* Embryology and Practical Anatomy, if taken together, £3 3s.

A Class in Fevers is held in the Belvidere Hospital (£1 1s.), and a Class in Vaccination at the Royal Infirmary (£1 1s.).

qualified Resident Medical Assistants are appointed every six months. Clinical Clerks and Dressers are attached to the Physicians and Surgeons, and students are appointed as assistants in the Pathological Department. There are in connexion with the clinical courses Tutorial Classes in Medicine and Surgery. Instruction is also given in Practical Pharmacy and Materia Medica and in Practical Dentistry. Full information can be obtained from Dr. H. E. Fraser, Medical Superintendent.

ROYAL ASYLUM.—Lectures on Mental Diseases and clinical instruction in connexion with University College, Dundee (University of St. Andrew's), are given at the University and at the Royal Asylum by Dr. Rorie. There are two paid qualified Resident Assistants and two unpaid Resident Clinical Assistants. The last Summer Session began on April 25th, 1900, and the course consisted of 12 Lectures at University College and 13 Clinical Lectures and Demonstrations at the Royal Asylum. Edward James Tyrrell and Margaret Scott Dickson obtained Certificates of Merit. Present Medical Assistant: Wm. Tuach, M.B., Ch.B. Clinical Assistants: Mr. Chauncy and Mr. Brownlee. The next Session will begin on April 24th, 1901.

### ABERDEEN.

ABERDEEN ROYAL LUNATIC ASYLUM.—Contains, with hospital attached to main institution and Agricultural Branch, about 850 beds. Medical Superintendent: Dr. William Reid. Assistant Physicians: Dr. W. R. Matthews, Dr. J. H. Mackay, Dr. Arthur L. Sutherland, and Dr. John McKenzie. Clerk, Treasurer, and Factor: Mr. Charles M. Brown. Clinical instruction is given to students during three months in summer.

ABERDEEN ROYAL INFIRMARY.—Contains over 230 beds. Consulting Physician: Dr. P. Blaikie Smith. Physicians: Dr. Angus Fraser, Professor Finlay, and Dr. George M. Edmond. Assistant Physicians: Drs. John Gordon, A. H. Lister, and Ashley W. Mackintosh. Consulting Surgeons: Professor Alexander Ogston, Dr. J. C. O. Will. Surgeons: Drs. R. J. Garden, J. McK. Booth, and J. S. Riddell. Assistant Surgeons: Drs. W. Sinclair, J. Marnoch, and H. M. W. Gray. Ophthalmic Surgeon: Dr. C. H. Usher. Gynæcologist: Professor W. Stephenson. Pathologist: Professor David James Hamilton. Assistant Pathologist: Dr. G. M. Duncan. Dental Surgeons: Dr. J. M. P. Crombie and Mr. John Cromar. Anæsthetist: Dr. J. J. Y. Dalgarno. Assistant ditto: Dr. W. R. Pirie. Medical Electrician: Dr. J. R. Levack. Clinical Registrar: Dr. J. F. Christie. Medical Superintendent: Dr. Charles Angus. Clerk and Treasurer and Factor for the Hospital Lands: Mr. Charles M. Brown.

## HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

ROYAL INFIRMARY, Edinburgh.—Beds are set apart for clinical instruction by the professors of the University of Edinburgh. Courses of Clinical Medicine and Surgery are also given by the ordinary physicians and surgeons. Special instruction is given in the medical department on Diseases of Women, Physical Diagnosis, and on Diseases of the Skin; and in the surgical department on Diseases of the Eye, the Ear, the Larynx, and the Teeth. Separate wards are devoted to Venereal Diseases, Diseases of Women, Diseases of the Eye, the Ear, and the Skin, and also to cases of Incidental Delirium or Insanity. Three wards are specially set apart for Clinical Instruction to Women Students. Post-mortem examinations are conducted in the anatomical theatre by the pathologists, who also give practical instruction in Pathological Anatomy and Histology. The fees for hospital attendance are as follows—viz.: Perpetual ticket, in one payment, £12; annual ticket, £6 6s.; six months, £4 4s.; three months, £2 2s.; monthly, £1 1s. Separate payments amounting to £12 12s. entitle the student to a perpetual ticket. No fees are paid for any medical or surgical appointment. The appointments are as follows:—1. Resident physicians and surgeons are appointed, and live in the house free of charge. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Non-resident house physicians and surgeons are appointed for six months. The appointment may be renewed for a like period by special recommendation. 3. Clerks and dressers are appointed by the physicians and surgeons. These appointments are open to all students and junior practitioners holding hospital tickets. 4. Assistants in the Pathological Department are appointed by the pathologists.

ROYAL HOSPITAL FOR SICK CHILDREN, Sciennes-road, Edinburgh.—This hospital, which has been recently built, contains over 100 beds, and is fitted with every modern improvement. A fully-equipped out-patient department (medical and surgical) is conducted daily in a building adjoining the hospital. Systematic courses of instruction, which qualify for graduation in the Edinburgh University and elsewhere, are given from time to time throughout the year by the staff. Students may enter at any time. Full particulars can be obtained from the Registrar at the hospital.

EYE, EAR, AND THROAT INFIRMARY OF EDINBURGH, 6, Cambridge-street, Lothian-road.—The Infirmary has been entirely re-arranged and greatly improved by recent structural alterations and the electric light introduced; also the electric power is used for illumination and cauterising purposes in all departments. Clinical Lectures and Instruction are given in this institution, which is open at 1 o'clock daily for outdoor patients for Eye Diseases; Mondays, Thursdays, and Saturdays at 12 noon for outdoor Ear, Nose, and Throat Patients; and Tuesdays and Fridays at 4 P.M. for outdoor Ear, Nose, and Throat Patients. Special Practical Ophthalmoscopic Classes by arrangement. Patients whose diseases require operations or more than ordinary care are accommodated in the house. Consulting Surgeon: Dr. Joseph Bell. Surgeons: Dr. G. Hunter Mackenzie, Dr. William George Sym, Dr. Logan Turner, Dr. Malcolm Farquharson, and Dr. John Cumming. Dental Surgeon:

Mr. G. W. Watson. Treasurer and Secretary: Mr. J. P. Watson, W.S., 13, Hill-street.

GLASGOW HOSPITAL AND DISPENSARY FOR DISEASES OF THE EAR, 28, Elmbank-crescent.[2]—The hospital, which contains 12 beds for indoor patients, is always open for urgent cases. Hours of surgeons' visits, 2 P.M. daily; clinical teaching daily. Out-patients are seen on Mondays, Tuesdays, Wednesdays, Thursdays, Fridays, and Saturdays, at 2 P.M., by Dr. Barr and assistants. Course of Lectures and Clinical Instruction given during winter months by Dr. Barr.

GLASGOW WESTERN INFIRMARY.—This hospital adjoins the University of Glasgow. Number of beds upwards of 420. Special wards are set apart for Diseases of Women and for Affections of the Skin. In the out-patient department there are special cliniques for Diseases of Women and for Diseases of the Throat, Ear, and Teeth. The Clinical Courses are given by the Physicians and Surgeons, each of whom conducts a separate class, and students require to enter their names at the beginning of the session for the class which they propose to attend. Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class. All the courses of clinical instruction are recognised by the University of Glasgow and the other boards in the kingdom. In the Pathological Department the course is both systematic and practical, also post-graduate courses, and extends through the winter and following summer; these are likewise recognised by the University for graduation. Ten resident assistants are appointed annually, without salary, from those who have completed their course. The fee for the hospital practice, including the various courses of clinical instruction, is 20 guineas in one payment, or in two equal instalments for the first and second year; for six months, 7 guineas; and for three months, 4 guineas.

ROYAL HOSPITAL FOR SICK CHILDREN, Glasgow, situated at Garnethill.—This Hospital was opened in December, 1882, and is now available to medical students for clinical instruction in the diseases peculiar to childhood. The hospital includes 80 beds for non-infectious cases only. A specially designed Dispensary, or Out-patient Department, was opened in October, 1888. Students may be enrolled at any time. Fee £1 1*s.* per annum, admitting to both Hospital and Dispensary. Particulars on applying to the House Surgeon, 45, Scott-street, Garnethill, Glasgow.

GLASGOW OPHTHALMIC INSTITUTION, 126, West Regent-street (31 beds and four cots).—Clinical and systematic course of lectures for students during the winter and summer sessions. In-patients, 772; out- or dispensary patients, 3713. Operations on Wednesdays and Saturdays. Consulting Surgeon: D. N. Knox, M.B., C.M., F.F.P.S.G. Acting Surgeon: A. Maitland Ramsay, M.D. Senior Assistant Surgeon: John Rowan, M.B., C.M. Junior Assistant Surgeons, Hugh Walker, M.B., C.M., and H. Wright Thomson, M.B., C.M. Pathologist: Hugh Walker, M.B., C.M. House Surgeons: Alex H. Edwards, M.B., C.M., and A. Bankier Sloan, M.B., Ch.B. This institution is the Ophthalmic Department of the Royal Infirmary. A post-graduate course is given by Dr. Ramsay and assistants during November and December. Clinical instruction is given in the summer session to students of Queen Margaret College and in winter to students of St. Mungo's College and to all who take the class.

GLASGOW EYE INFIRMARY, Berkeley-street and Charlotte-street.—This institution, the largest of its kind in Scotland, was founded in 1824. The Infirmary now consists of two large buildings—that in Berkeley-street being occupied as the Infirmary proper, and that in Charlotte-street (new buildings opened June, 1894) as a dispensary. The Infirmary is devoted exclusively to the treatment of Diseases of the Eye, and is intended primarily to provide treatment, and, when necessary, board and lodging, for those who are unable to do so for themselves. The average number of new patients for the last ten years has been 15431·3, and the total number of cases treated in 1899 was 21,130. The Medical Staff is as follows:—Senior Surgeon: Thomas Reid, M.D. Surgeons: Thomas S. Meighan, M.D., A. Freeland Fergus, M.D., William Robertson, M.D., Andrew Wilson, M.B., C.M., James Hinshelwood, M.A., M.D. Assistant Surgeons: A. Lewis M'Millan, M.D; W. Ernest Thomson, M.A., M.D.; Henry L. G. Leask, M.D.; W. Cochrane Murray, M.B., C.M.; Leslie Buchanan, M.B., C.M.; Brownlow Riddell, M.D.; James D. Cochran, M.B., Ch.B. Pathologist: Leslie Buchanan, M.B., C.M. House Surgeon: William C. Burns, M.B., Ch.B. Assistant House Surgeon: George Coats, M.B., Ch.B.

*Regulations as to Attendance of Students.*—(1) Gentlemen may attend as students on payment to the treasurer of the following fees:—For six months £1 1*s.*, twelve months £2 2*s.* (2) All students when duly entered in the Infirmary Register may attend the clinical instruction of any or every member of the medical staff on production of their tickets. The days on which the surgeons respectively attend to receive patients may be ascertained at the Infirmary. Students have the privilege of being present in the Dispensaries at such hours as are arranged. They may enter the wards along with the surgeon whose clinique they are attending when he visits his patients. They may also be present at operations under the sanction of the surgeon operating, but no student may enter the wards or operating-room except under the aforesaid regulation. Students may be allowed the use of the journals and case-books for examination on applying to the House Surgeon. The wards and dispensary are recognised by the University of Glasgow for the purpose of instruction in ophthalmology for graduation in medicine. Secretary and acting Treasurer: William George Black, 88, West Regent-street. Medical session begins April.

[2] No returns.

## IRISH SCHOOLS OF MEDICINE.[1]

QUEEN'S COLLEGE SCHOOL OF MEDICINE, Belfast.—Ten Junior Scholarships have been founded in the Faculty of Medicine of the annual value of £20 each. Two are tenable by matriculated students, of the first, second, third, fourth, and fifth years of their course respectively. The examinations for Scholarships take place at the commencement of the session. Class Prizes are awarded at examinations which take place at the close of the session. The Exhibitions, &c., of the Royal University of Ireland are also open to students. Lectures in Medicine at Queen's College, Belfast, will commence on Oct. 16th and end on March 30th. The Summer Session will begin on May 1st. Clinical instruction is given at the Royal Hospital. The Ulster Hospital for Diseases of Women and Children, the Maternity Hospital, the Ophthalmic Hospital, the Ulster Eye, Ear, and Throat Hospital, the Hospital for Sick Children, and the District Lunatic Asylum are open to students. A pamphlet containing full information can be had free on application to the Registrar, Queen's College, Belfast.

QUEEN'S COLLEGE SCHOOL OF MEDICINE, Cork.—The building is provided with a very large, well-ventilated dissecting-room, with physiological, toxicological, and pathological laboratories, materia medica, anatomical and pathological museums, as well as a room for surgical and obstetrical instruments and appliances. There are well-appointed physical, chemical, and biological laboratories, and a large natural history museum in the adjoining building, and part of the College ground is laid out as a botanical garden. The plant houses are well filled with plants and are open to the students in the class of Botany.

*Fees.*—For Practical Anatomy and for Practical Chemistry, £3 each course; for Anatomy and Physiology, £3 first course, and £2 for each subsequent course. Other medical classes, £2 first course, and £1 each subsequent course. Eight scholarships (value about £30 each), as well as several exhibitions and class prizes, are open to students in their first four years and the Blayney Scholarship, value £35, and a Senior Exhibition to students in their fifth year.

### HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

ADELAIDE MEDICAL AND SURGICAL HOSPITALS, Peter-street, Dublin.—Fee for nine months' hospital attendance, £12 12*s.*; six months, £8 8*s.* Summer, three months, £5 5*s.*

*Staff.*—Physicians: James Little, M.D., M.R.I.A.; Wallace Beatty, M.D., F.R.C.P.I.; H. T. Bewley, M.D., F.R.C.P.I. Surgeons: F. T. Heuston, M.D., F.R.C.S.I.; T. E. Gordon, M.B., F.R.C.S.I. Obstetric Surgeon: W. J. Smyly, M.D., F.R.C.P.I. Ophthalmic Surgeon: H. R. Swanzy, M.B., F.R.C.S.I. Pathologist and Bacteriologist: J. Alfred Scott, M.D. F.R.C.S.I. Assistant

* In Summer. † In Winter and in Summer. ‖ Zoology in Winter; Botany in Summer. § Including Biology. ¶ And Hygiene.

Physician: G. Peacocke, M.D., F.R.C.P. Assistant Surgeon: K. E. Levison-Gower Gunn, M.D., F.R.C.S. House Surgeon: Ashton Bond, M.B., B.Ch.

A resident surgeon is elected yearly and three resident pupils half-yearly. At the termination of the session prizes in Clinical Medicine and Surgery and in Obstetric Medicine will be awarded.

*Hudson Scholarship.*—In addition to the junior prizes, the Hudson Scholarship, £30 and a gold medal as well as a prize of £10, together with a silver medal, will be awarded at the end of the session for proficiency in Clinical Medicine and Medical Pathology, Clinical Surgery and Surgical Pathology, Pathological Histology, Surgical Appliances, including instruments and bandaging, Ophthalmology and Gynæcology.

The certificates of attendance are recognised by all the Universities and licensing bodies in the United Kingdom. Further particulars may be obtained from Mr. F. T. Heuston.

COOMBE LYING IN HOSPITAL AND GUINNESS DISPENSARY FOR THE TREATMENT OF DISEASES PECULIAR TO WOMEN, Dublin.—This hospital contains nearly 70 beds and consists of two divisions, one of which is devoted to lying-in cases and the other to the treatment of the diseases peculiar to women. The maternity department is one of the largest in Ireland, 3000 cases being annually treated either as intern or extern patients. A regular course of lectures is delivered in the hospital, and clinical instruction is given daily at the bedside. There are two large dispensaries connected with the institution, at one of which instruction is given on the General Diseases of Women and Children, and in the other on the Diseases Peculiar to Women. There is accommodation for a limited number of intern pupils, who enjoy exceptional advantages of acquiring a practical knowledge of this branch of their profession. Two Resident Pupil Midwifery Assistants and one Clinical Clerk are elected half-yearly from among the pupils of the hospital. Certificates of attendance at this hospital are accepted by all licensing bodies, and the diploma is recognised by the Local Government Board as a full legal midwifery qualification. Fees (six months' course): extern pupils, 8 guineas, half payable in advance; intern pupils, 18 guineas for six months' residence. If pupils enter as interns by the month the fees are £4 4*s.* for first month, and £3 3*s.* for each succeeding month. Intern pupils enjoy very special advantages, which can be learned on application. Registration fee on entrance, 10*s.* 6*d.* Students can enter for attendance at any time. Further particulars may be had on application to the Master or the Registrar at the hospital.

SIR PATRICK DUN'S HOSPITAL [2]—Fees for attendance of students—nine months, £12 12*s.*; six months, £8 8*s.*; three months, £5 5*s.* The hospital is open to extern students as well as to the students of Trinity College, and the certificates are recognised by all the licensing bodies in the kingdom. Dr. Taylor, Secretary to the Medical Board, will give any further information.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.[3]—This hospital was founded in 1753 and now contains 160 beds available for clinical teaching. A new building for the isolated treatment of fevers has recently been added. The certificates of this hospital are recognised by all the universities and licensing bodies of the United Kingdom. Medical and Surgical Resident Pupils and Clinical Clerks and Dressers are appointed every six months, and a House Surgeon is elected annually. A prospectus giving the complete arrangements for the Medical and Surgical classes for the coming session may be obtained from the Secretary of the Medical Board, R. Glasgow Patteson, F.R.C.S., 20, Lower Baggot-street, Dublin.

MATER MISERICORDIÆ HOSPITAL, Dublin.[4]—Consulting Physician: Sir Francis R. Cruise. Physicians: Sir Christopher Nixon, Dr. Joseph Redmond, Dr. John Murphy, and Dr. Martin Dempsey. Assistant Physician: Dr. John O'Donnell. Surgeons: Messrs. Patrick Hayes, Charles Coppinger, Arthur Chance, and John Lentaigne. Assistant Surgeon: Mr. Hugh Blaney. Obstetric Physician: Dr. Thos. More Madden. Ophthalmic Surgeon: Mr. Louis Werner. Dental Surgeon: Mr. Daniel Corbett, jun. Pathologist: Dr. Edmond McWeeney. Anæsthetist and Surgical Registrar: Dr. Michael O'Sullivan. House Physicians: Dr. Patrick Canning and Dr. John Murray. House Surgeons: Messrs. Matthew J. Russell, Joseph P. Quinn, John Keogh, and Thomas O'C. Donelan. This hospital, the largest in Dublin, at present containing 335 beds, is open at all hours for the reception of accidents and urgent cases. Fifty beds are specially reserved for the reception of patients suffering from fever and other contagious diseases. Instruction at the bedside will be given by the Physicians and Surgeons at 9 A.M. daily. Clinical Instruction will commence on Monday, Oct. 2nd, at 9 A.M. A course of Clinical Instruction on Fever will be given during the winter and summer sessions. A certificate of attendance upon this course, to meet the requirements of the licensing bodies, may be obtained. Opportunities are afforded for the study of Diseases of Women in the ward under the care of the Obstetric Physician, and at the Dispensary held on Tuesdays and Saturdays. Ophthalmic Surgery will be taught in the Special Wards and Dispensary. Surgical Operations will be performed on Mondays, Tuesdays, Fridays, and Saturdays at 11 o'clock. Connected with the hospital are extensive Dispensaries, which afford valuable opportunities for the study of general Medical and Surgical Diseases, Accidents, &c. Instruction will be given on Pathology and Bacteriology. Junior Appointments: Four House Physicians and eight House Surgeons will be appointed annually. Ten resident pupils will be elected from the most attentive of the class to hold office for six months. For the current session the elections will take place in November, 1899, and in May, 1900. Dressers and Clinical Clerks will be appointed, and certificates will be given to those who perform their duties to the satisfaction of the staff. Leonard Prizes: One Gold and one Silver Medal will be offered for competition annually in the subject of Medicine, and one Gold and one Silver Medal in the subject of Surgery. Junior Leonard Prizes: One prize value £3 and one prize value £2 will be awarded in Medicine, and one prize value £3 and one prize value £2 will be awarded in Surgery. They will be awarded on the aggregate of marks gained for Reports of Cases and at a Clinical Examination to be held at the close of the summer session. For further particulars see prospectus. Certificates of attendance upon this hospital are recognised by all the Universities and licensing bodies in the United Kingdom. Private Wards have been opened for the reception of Medical and Surgical cases. A Training School and Home for Trained Nurses have been opened in connexion with the Hospital.

*Terms of attendance.*—Nine months, £12 12*s.*; six winter months, £8 8*s.*; three summer months, £5 5*s.* Entries can be made with any of the physicians or surgeons, or with the Registrar, Arthur Chance, F.R.C.S., 90, Merrion-square. A prospectus containing in detail the arrangements for Clinical Instruction, Prizes, &c., may be obtained from the Secretary, Dr. Joseph Redmond, 41, Merrion-square, E., Dublin.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS, North Brunswick-street, Dublin.—These hospitals contain 312 beds—110 for Surgical cases, 82 for Medical cases, and 120 for Fever and other epidemic Diseases. A Resident Physician and a Resident Surgeon are appointed each year and are paid for their services. Clinical Clerks: Five Resident Clinical Clerks are appointed each half-year, and provided with furnished apartments, fuel, &c. These appointments are open not only to advanced Students as formerly, but also to those who are qualified in Medicine or Surgery. The Dressers are selected from among the best qualified of the pupils without the payment of any additional fee. For prospectuses apply to Sir W. Thomson, F.R.C.S., Treasurer, 54, Stephen's-green East; or to J. O'Carroll, M.D., Honorary Secretary, 43, Merrion-square, Dublin.

ROTUNDA HOSPITAL, Rutland-square, Dublin.—This institution consists of two distinct hospitals—namely, the Lying-in Hospital and the Auxiliary Hospital, the latter for the reception of patients suffering from Uterine and Ovarian Diseases. There is also a large extern maternity and a Dispensary for Diseases Peculiar to Women, which is open daily. Clinical instruction is given daily (Saturdays excepted) in Midwifery and the Diseases peculiar to Women, special attention being directed to the application of antiseptics in Midwifery. Accommodation is provided for a limited number of intern pupils. Consulting Physician: Dr. James Little. Consulting Surgeon: Sir Philip C. Smyly. Master: Dr. R. Dancer Purefoy. Assistant Physicians:

[2] No returns. [3] No returns. [4] No returns.

Dr. H. C. Lloyd and Dr. P. Carton. Clinical Clerks: Dr. A. Gills and Dr. W. L. Watt.

DR. STEEVENS'S HOSPITAL.[5]—This hospital, containing beds for 200 patients, is situated close to the Kingsbridge Terminus of the Great Southern and Western Railway, occupying a position in the centre of one of the busiest manufacturing districts of the city, otherwise unprovided with medical institutions, and affords exceptional advantages for clinical instruction. Immediately adjoining is St. Patrick's (Swift's) Asylum for the Insane. The hospital is easily accessible by two lines of tramways. There is a ward entirely devoted to Venereal Disease, a detached building for Fever Cases, and an extensive Out-patient Department, with separate Clinics for Diseases of the Skin, Throat, Eye, Ear, Teeth, and Women.

The hospital is visited daily by the physicians and surgeons. The wards are also visited by the resident surgeon each evening. Clinical Lectures are given by the physicians and surgeons during the session. There is accommodation in the hospital for four medical, six surgical, and two special resident clinical assistants.

*Fees.*—Hospital Practice: Nine months, £12 12*s.*; six months, £8 8*s.*; three months, £5 5*s.* Dressership: £10 10*s.* each three months. Further information may be obtained from the Resident Surgeon or from R. A. Hayes, M.D., Honorary Secretary, 82, Merrion-square South.

Dr. J. Beatty has been appointed Assistant Physician, Mr. W. S. Haughton Surgeon, and Dr. P. Kirkpatrick Anæsthetist to the hospital.

# PUBLIC HEALTH.

## INSTRUCTION FOR DIPLOMAS IN STATE MEDICINE.

### ENGLAND.

THE following recommendations, designed with a view of ensuring "the possession of a distinctively high proficiency, scientific and practical, in all the branches of study which concern the public health," were adopted by the General Medical Council in 1896.[1] The regulations require that—"(1) A period of not less than twelve months shall elapse between the attainment of a first registrable qualification in Medicine, Surgery, and Midwifery and the examination for a diploma in Sanitary Science, Public Health, or State Medicine; (2) every candidate shall have produced evidence of having attended, after obtaining a registrable qualification, during a period of six months, practical instruction in a laboratory approved of by the body granting the qualification; (3) every candidate shall have produced evidence of having for six months practically studied the duties of outdoor sanitary work either under a medical officer of health who is a teacher in public health in a recognised school, or under the medical officer of health of a county or of a single sanitary district of 50,000, or a combination of districts of 35,000 inhabitants in England, or in one or more districts of 30,000 in Scotland or Ireland; (4) the examination shall have been conducted by examiners specially qualified, and shall comprise laboratory work as well as written and oral examination; (5) the rules as to study shall not apply to medical practitioners registered, or entitled to be registered, on or before Jan. 1st, 1890." It was enacted by Section 18 (2) of the Local Government Act [England and Wales], 1888, that after Jan. 1st, 1892, no such appointment (that of medical officer of health) may be made in any county, or in any district or combination of districts with a population of 50,000 or upwards, unless the officer—having, of course, qualifications in Medicine, Surgery, and Midwifery—is registered as the holder of a diploma in Sanitary Science, Public Health, or State Medicine under Section 21 of the Medical Act, 1886, or has during any three consecutive years preceding 1892 been medical officer of a district or combination of districts with a population of 20,000 at least, or has for three years previously to August 13th, 1888, been a medical officer or inspector of the Local Government Board. With the sanction of the Local Government Board the same person may be appointed medical officer for two or more districts. It would seem, however, that the regulations of the General Medical Council may be undergoing revision; and, if this be so, the amended regulations are not likely to be less stringent—at least for recently qualified men—than those at present in force. It may, therefore, be well for those who are contemplating the taking of the diploma not to delay matters.

*London University.*—Sanitary Science is included under the head of State Medicine in the M.D. degree, and a certificate has to be produced showing that a course of practical instruction has been attended for the prescribed period, and that the course has included such chemical, microscopical, and meteorological work and exercises as more especially relate to sanitation. The attendance includes six months' practical instruction in a laboratory and six months' outdoor sanitary work. Certificates will be received from the holder of any public health office directly or indirectly subject to control by a Secretary of State or a Government Department. Candidates for the M.D. degree in State Medicine must have (1) studied State Medicine for two years or (2) have studied State Medicine for one year and have held for a period of two years the position of medical officer of health in any sanitary district, or (3) without having studied State Medicine have held for a period of three years the position of medical officer of health in any sanitary district.

*Cambridge University.*—Two examinations in so much of State Medicine as is comprised in the functions of medical officers of health will be held during the year 1900 in Cambridge. Each examination will consist of two parts. Part I. will begin on the first Tuesday in April and October respectively; Part II. will begin on the second Tuesday in April and October respectively; and each part will end on the following Thursday. Any person whose name is on the Medical Register is admissible as a candidate for this examination provided (1) a period of not less than twelve months shall have elapsed between the attainment of registrable qualification and the time when he presents himself for either part of the examination; (2) he produce evidence of having, before or after obtaining a registrable qualification, attended the clinical practice of a hospital for infectious diseases approved by one of the licensing bodies recognised under the Medical Acts; (3) he produce evidence of having, after obtaining a registrable qualification, attended during a period of six months on one or more courses, approved by the Syndicate, of practical laboratory instruction in Chemistry, Bacteriology, and the Pathology of those diseases of animals that are transmissible to man; (4) he produce evidence of having, after obtaining a registrable qualification, practically studied for six months the duties of outdoor sanitary work. (*a*) In England and Wales either under the medical officer of health of a county or of a single sanitary district having at the date of the last census a population of not less than 50,000 or the medical officer of health of a combination of two or more sanitary districts having collectively at the date of the last census a population of not less than 35,000; or (*b*) in Scotland or Ireland under the medical officer of health of a county or of one or more sanitary districts having at the date of the last census a population of not less than 30,000; or (*c*) under a medical officer of health who is a teacher in the department of public health of a recognised medical school. A certificate of an assistant officer of health of a county or a large urban district may be accepted, provided the medical officer of health of a county or district consents to the assistant officer giving such instruction. Any candidate who shall produce evidence that he has himself held an appointment as medical officer of health under conditions not requiring the possession of a special sanitary diploma shall be exempt from this regulation. The provisions as to previous study shall not apply to medical practitioners registered, or entitled to be registered, on or before Jan. 1st, 1890. The first part of the examination will have reference to the general principles of sanitary science and will comprise the following subjects. The elements of chemistry and physics: methods of chemical analysis and in particular the analysis of air and water. The laws of heat and the elements of pneumatics, hydrostatics, and hydraulics in their application to warming, ventilation, water-supply, and drainage. The geological and other conditions determining the healthiness of sites for dwellings. Sources, storage, and purification of water-supply. The elements of meteorology in relation to health. Principles of building construction in their application to dwellings,

[5] No returns.

[1] The regulations were last settled on June 9th, 1896, and came into operation on Jan. 1st, 1897.

hospitals, and schools. The disposal of sewage and refuse, and the general principles of sanitary engineering. Disinfectants, their chemistry and use. The chemical and microscopical examination of foods and the detection of the commoner forms of contamination. The methods of bacteriological investigation and analysis. The bacteriology of air, water, food, and soil. The general pathology of infection, and of the diseases of animals that are transmissible to man. The second part of the examination will have reference to State Medicine and to the applications of Pathology and Sanitary Science, and will comprise the following subjects. Laws and Statutes relating to Public Health.[2] The model by-laws of the Local Government Board. Sanitation of dwellings, schools, factories, and workshops, and of villages and towns. Inspection of slaughter-houses, cowsheds, &c. Inspection of meat and other articles of food. General epidemiology, with special reference to the origin, pathology, symptoms, propagation, geographical distribution, and prevention of the epidemic, endemic, and other infective diseases both of temperate and of tropical climates. The methods applicable to the medical investigation of epidemics. Effects on health of overcrowding, vitiated air, impure water, polluted soils, and bad or insufficient food. Unwholesome trades and occupations, and the diseases to which they have rise. Nuisances injurious or dangerous to health. The effects on health of season and climate. The principles and methods of vital statistics in relation to public health. (N.B.—The foregoing schedule is not to be understood as limiting the scope of the examination, which will include every branch of sanitary science. No candidate will be approved by the examiners who does not show a high proficiency in all the branches of study, scientific and practical, which bear upon the duties of medical officers of health.) The following is a list of colleges and schools of medicine at which the courses of laboratory instruction have, for the purposes of this examination, been already approved by the State Medicine Syndicate: The Chemical and Pathological Laboratories, Cambridge; the London Hospital Medical College; St. Bartholomew's Hospital Medical College; King's College, London: University College, London; the Army Medical School, Netley; Owens College, Manchester; the University of Durham Medical School, Newcastle-on-Tyne; Mason College, Birmingham; University College and Royal Southern Hospital School, Liverpool; St. Mary's Hospital Medical College; Charing-cross Hospital College; Westminster Hospital Medical School; University College, Bristol; Yorkshire College, Leeds; Guy's Hospital Medical School; St. Mungo's College, Glasgow; Edinburgh University Public Health Laboratory; Middlesex Hospital Medical School; Royal Colleges, Edinburgh; Surgeons' Hall, Edinburgh; British Institute of Preventive Medicine; Trinity College, Dublin; Queen's College, Belfast; St. Thomas's Hospital Medical School; University College, Cardiff; and University College, Sheffield. The examination in both parts will be oral and practical, as well as in writing. One day at least will be devoted to practical laboratory work and one day to oral and practical examination in, and reporting on, subjects connected with outdoor sanitary work. Candidates may present themselves for either part separately or for both together at their option; but the result of the examination in the case of any candidate will not be published until he has passed to the satisfaction of the examiners in both parts. Every candidate will be required to pay a fee of £6 6*s*. before admission or re-admission to *either part* of the examination, but candidates who have presented themselves before the year 1896 will be re-admitted to either part on payment of a fee of £5 5*s*. Every candidate who has passed both parts of the examination to the satisfaction of the examiners will receive a diploma testifying to his competent knowledge of what is required for the duties of a medical officer of health. All applications for information respecting this examination should be addressed to Dr. Anningson, Walt-ham-sal, Barton-road, Cambridge, Secretary to the Syndicate. Candidates who desire to present themselves for the examination must send in their applications on forms supplied for the purpose and transmit them with the fees to J. W. Clark, M.A., Registrary, University of Cambridge, for the April examination on or before March 17th and for the October examination on or before Sept. 15th. The prescribed certificates must be sent to the Registrary so as to reach him not later than 10 A.M. on March 29th and Sept 27th respectively. Cheques should be crossed "Barclay and Co., Ltd." The fee for either part of the examination cannot be returned to any candidate who fails to present himself; but he will be entitled, without an additional fee, to be a candidate on one subsequent occasion. Candidates must before admission to either part of the examination produce proof of having satisfied provisions (1), (2), and (3), and before admission to the second part having satisfied provisions (4), above mentioned.

*University of Oxford (Diploma in Public Health).*—An examination, open to all registered medical practitioners, conducted partly in writing, partly *viva voce*, and in each subject partly practical, is held in Michaelmas Term in the following subjects:—General Pathology (with special relation to Infectious Diseases), the Laws relating to Public Health, Sanitary Engineering, Vital Statistics. The fee for admission to the examination is £10. Candidates (*a*) must have spent after registration a period of at least six months studying in a public health laboratory approved by the Board of the Faculty of Medicine. Candidates must also (*b*) have had their names on the Medical Register of the United Kingdom for a period of at least twelve months; (*c*) have spent after registration a period of study of not less than six months in all, under the medical officer of health of a county or of a city or town containing at least 50,000 inhabitants, or under two or more such medical officers of health. Certificates of proficiency are granted to those who pass this examination.

*University of Durham.*—Sanitary Science is the special object of the degrees in Hygiene. Candidates for the degree of Bachelor in Hygiene (B. Hy.) must be at least twenty-two years of age and registered, and before presenting themselves for examination must have been for at least twelve months graduates in Medicine of a recognised university. They shall spend six months at Newcastle-upon-Tyne studying Public Health, Comparative Pathology, Practical Bacteriology, Outdoor Sanitary Work, Infectious Diseases, Sanitary and Practical Chemistry. They have to pass an examination in Sanitary Chemistry, Physics, Sanitary Legislation, Comparative Pathology, Vital Statistics, Nosology, Distribution of Health and Disease, Sanitary Medicine and Practical Hygiene. The fee for the examination for the degree of B.Hy. is 10 guineas, and for the degree £6 6*s*. The examination is divided into two parts and candidates may present themselves for either part or both together at their option. Candidates for the degree of Doctor in Hygiene (D.Hy.) must have acquired the degree of Bachelor in Hygiene, must for two years subsequently have been engaged in practice as a medical officer of health and must write an essay upon some practical hygienic subject. The fee for the examination for the degree of D.Hy. is £5, and for the degree £6 6*s*. The regulations for education and examination for the Diploma in Public Health (D.P.H.) are the same as those for the degree of Bachelor of Hygiene, except that the candidate is not required to be a graduate in Medicine of a recognised University, and the course of study need not be passed at Newcastle-upon-Tyne. The fee for the examination and Diploma in Public Health is ten guineas.

*Victoria University.*—An examination in Public Health is held yearly under the following regulations: The examination is in two parts, and is written, oral, and practical. Candidates before entering for either part of the examination must have held for not less than twelve months a registrable qualification in Medicine, Surgery, and Midwifery, and must present satisfactory certificates of having attended courses of instruction in Public Health in a college of the University, or in a college or medical school recognised for this purpose by the University; of having attended, after obtaining a registrable qualification, during at least six months, practical instruction in a laboratory approved by the University, the courses including Chemistry as applied to Public Health, Bacteriology, and the Pathology of those diseases of animals which are communicable from animals to man; of having attended for three months the clinical practice of a hospital for infectious diseases; of having practically studied the duties of outdoor sanitary work for not less than six months under the medical officer of health of a county

[2] All candidates will be examined in the provisions of the English Statutes relating to public health, but any candidate will be given an opportunity of showing a special knowledge of other sanitary laws in operation within the British Empire, provided that, *when applying for admission to the examination, he give notice* of his desire and indicate the special law he proposes to offer.

or of a large urban district. Candidates may present themselves for Parts I. and II. separately or at the same time, provided that no candidate be admitted to Part II. unless he has already passed in Part I. No candidate's name will be published until he has satisfied the examiners in both parts of the examination The fee for each part is £5 5*s*., and must be paid on or before July 1st in each year. For any subsequent examination in the same part the fee will be £3 3*s*. Every candidate who has passed both parts of the examination to the satisfaction of the examiners, and who is legally registered, will receive a Diploma in Public Health. The examinations will begin on the third Monday in July each year.

*Royal College of Physicians of London and the Royal College of Surgeons of England.* — The following are the regulations for obtaining the Diploma in Public Health: Section 1: Candidates must be registered under the Medical Act. The examination consists of two parts. The fee for each part is £5 5*s*. A candidate intending to present himself must give fourteen days' written notice to the Secretary, at the Examination Hall, Thames Embankment, W.C. A candidate registered under the Medical Act on or before Jan. 1st, 1890, will be admissible to Part I of the examination on producing evidence of being at least twenty-three years of age, and to Part II. on producing evidence of being at least twenty-four years of age. A candidate registered under the Medical Act after Jan. 1st, 1890, will be admissible to examination in Part I. on producing evidence (1) of having been in possession of a registrable qualification in Medicine, Surgery, and Midwifery for at least twelve months; (2) of having attended, after obtaining such registrable qualification, practical instruction in a laboratory recognised by the Examining Board in England during a period of six months; and (3) of being at least twenty-three years of age. A candidate will be admitted to Part II. of the examination on producing evidence (1) of having, during a period of six months after obtaining a registrable qualification, either practically studied the duties of outdoor sanitary work under the medical officer of health of a county or large urban district or else held appointment as medical officer of health under conditions not requiring the possession of a special Sanitary diploma; (2) of having attended the clinical practice of a hospital for infectious diseases recognised by the Examining Board in England, either before or after obtaining his registrable qualification in Medicine, Surgery, and Midwifery (this certificate is not required in the case of a candidate who produces evidence that he has commenced special study of Sanitary Science before Jan. 1st, 1894); and (3) of being at least twenty-four years of age.

*King's College, London.* — The necessary Laboratory Instruction to comply with the regulations of the various Universities and other Medical Licensing Bodies will be given by Professor William R. Smith, M.D., D.Sc., and Professor Edgar M. Crookshank, M.B. Lond. The syllabus includes Physics, Chemistry, Microscopy; Parasites and other Organisms Infesting Food-stuff or the Human Body; Bacteriology, including the Cultivation and Recognition of Micro-organisms. The course will last six months, four months of which will be spent in the Laboratories of Public Health, and two months in the Bacteriological Laboratory. Fee 20 guineas, payable in advance in the College office. Under the direction of Professor William R. Smith, M.D., D.Sc., and Demonstrator E. Russell, B.Sc., F.C.S., practical instruction will be given in the laboratories in the methods of Analysis of Air, Water, Foods, &c.; Detection of Poisons. Fees, one month, £4 4*s*.; three months, £10 10*s*. The laboratories are also available for original investigations and practical work in Public Health, and are open daily from 9 A.M. to 4 P.M. and on Saturdays to 1 P.M. In Public Health special classes will be held during the winter session by Professor W. R. Smith; fee, £12 12*s*. The Bacteriological Laboratory is open daily for original research under the direction of the professor and demonstrator of Comparative Pathology and Bacteriology. For one month for original research, 5 guineas. For a longer period by arrangement. For one month for private study, with supervision, 5 guineas. For a longer period by arrangement. Practical course for a month, with attendance on lectures, 5 guineas. For a year, 30 guineas. Professor H. G. Seeley, F.R.S., will deliver a course of six lectures on Physiography.

*University College, Bristol.*—A course of lectures on the Principles and Practice of Hygiene is given at the College by D. S. Davies, M.D. Lond., D.P.H. Cantab., on Mondays and Fridays, 10–11 A.M., commencing on the first Monday in October. A six months' course of Practical Laboratory Instruction is given at the Western Counties' Laboratory, Park-street, by Mr. F. Wallis Stoddart, commencing on the first Wednesday in October, and including the subjects of Chemistry and Physics. Instruction in Bacteriology is given at the College by Professor A. F. Stanley Kent, M.A., F.L.S., F.G.S. Demonstrations on the provisions and practical working of the various Acts relating to Public Health and on the Orders, Circulars, and By-laws of the Local Government Board are delivered by Mr. J. C. Heaven on Mondays and Fridays, commencing on the first Monday in October. Gentlemen taking out the course are admitted to practical outdoor sanitary work during the session, under the supervision of the medical officer of health for the city and port of Bristol. They are considered as pupil assistants and are required to carry out diligently such of the duties of medical officers of health as they may be directed to undertake. Facilities are afforded during the course for the study of those diseases of the lower animals which are communicable to man. Fee for the entire course, 20 guineas.

*University of Birmingham.*—The University grants a degree of B.Sc. in Public Health and also a Diploma in the same subject on the following conditions: Graduates in Medicine of this University may become candidates for the degree of Bachelor of Science in Public Health, by conforming to all the requirements laid down for candidates for the Diploma in Public Health, except that after graduating in Medicine all courses of study must be taken out in the University and they must, in addition, have attended a three months' course of Geology in the University. The following are the regulations for Diploma in Public Health (general conditions):—1. All candidates must be registered under the Medical Act. 2. The examinations will be held in the months of January and July, and will consist of two parts. No candidate will be admitted to Part II. until he has passed Part I. 3. Candidates may enter for Parts I. and II. separately or at the same time. 4. The examination in each part will be written, oral and practical. 5. Candidates intending to present themselves for either part of the examination must give 14 days' notice in writing to the registrar of the University. 6. The fee for each part of the examination is £5. The conditions of admission to the examinations are as follows:—I.—For candidates registered under the Medical Act on or before Jan. 1st, 1890. Candidates so registered will be allowed to sit for examination on producing certificate of registration. II.—For candidates registered under the Medical Act after Jan. 1st, 1890. Candidates will be admitted to examination in Part I. on producing evidence: (1) of being at least 23 years of age, and of having been possessed of a registrable qualification in Medicine, Surgery, and Midwifery, for a period of 12 months; (2) of having attended, after obtaining such registrable qualification, a six months' practical course of Hygienic Chemistry in a Laboratory recognised by the University; and (3) of having attended a course of Bacteriology. Candidates will be admitted to Part II. of the examination on producing evidence (1) of being at least 24 years of age; (2) of having during a period of six months after obtaining a registrable qualification, practically studied out-door sanitary work, under the medical officer of health of a county or large urban district with a population of at least 50,000, or under the medical officer of health of two or more combined districts with a similar population, or else held appointment as medical officer of health under conditions not requiring the possession of a Diploma in Public Health; and (3) of having attended the practice of a hospital for infectious diseases, recognised by the University, either before or after obtaining his registrable qualification.

*University College, Cardiff.*—During the last year a department of Public Health has been established at Cardiff, and courses of instruction in public health instituted, which have received the recognition of the University of Cambridge, of Victoria University, and of the Royal College of Physicians. At the beginning of the year Dr. W. G. Savage was appointed Lecturer in Bacteriology and later Dr. Edward Walford and Dr. William Williams were appointed lecturers in Public Health and Hygiene. The Cardiff Corporation and the Glamorgan County Council have placed their public health laboratory at the disposal of the college for teaching

purposes. During the last month Mr. John H. Sugden has been appointed assistant to the bacteriologist.

### SCOTLAND.

*Edinburgh University.*—Two degrees in Science in the Department of Public Health are conferred by the University of Edinburgh, viz., Bachelor of Science in Public Health and Doctor of Science in Public Health. Candidates for the degree of B.Sc. in Public Health must be graduates in Medicine of a University of the United Kingdom, or of some other University recognised for the purpose, and must pass two examinations, for the first of which they must, after graduation in Medicine, have worked for at least twenty hours per week during a period of not less than eight months, of which at least five consecutive months must be in the Public Health Laboratory of the University of Edinburgh and the remainder either there or in a laboratory recognised by that University; they must also have attended lectures on Physics and Geology in some Scottish University. Candidates are not admitted to the Second Examination sooner than six months after having passed the First Examination, nor sooner than eighteen months after having taken their degree in Medicine, and they must have attended two separate courses in Public Health in some University of the United Kingdom or in such medical school or Indian, Colonial, or Foreign University as may be approved for the purpose by Edinburgh University, each course consisting of forty lectures at least; one of these courses shall deal with medicine and the other with engineering, each in its relation to public health. They must also give evidence (1) that for six months they have practically studied sanitary work under the medical officer of health of a county or borough or district containing a population of not less than 25,000; (2) that they have had three months' clinical instruction regarding fevers and infectious diseases; and (3) that they have had three months' instruction in mensuration and drawing. The subjects of examination include Laboratory work, Physics, Geology, Medicine in its application to Public Health, Sanitation, Sanitary Law, and Vital Statistics. Graduates who have held the degree of B.Sc. in Public Health from the University of Edinburgh for a term of five years may offer themselves for the degree of D.Sc. in Public Health in that University. They must then present a Thesis and pass an examination in Public Health. The fees are £3 3*s.* for the First and £3 3*s.* for the Second B.Sc. Examinations, and £10 10*s* for the degree of D.Sc.

*University of Aberdeen.*—The Diploma in Public Health (D.P.H.) is conferred only on graduates in Medicine of a University in the United Kingdom; and a period of not less than twelve months must elapse between medical graduation and entrance to the examination for the diploma. Every candidate must produce evidence of having attended, after graduation in Medicine, during a period of six months, practical instruction in Hygiene and Bacteriology in laboratories approved of by the University, together with having for a like period after graduation practically and daily studied the duties of outdoor sanitary work under the medical officer of health of a county or large urban district, or of having himself held appointment as medical officer of health. He must also have regularly attended for six months the wards of a general fever hospital containing not less than fifty beds. Every candidate who is not a graduate in Medicine of this University must have attended a course of instruction in the University in one or more of the subjects embraced in the examination for the diploma. The diploma is conferred after an examination in Public Health held in March and July of each year. Candidates desiring to appear for examination at either of these periods must send in their names, with the necessary fee, to the Secretary of the Medical Faculty a fortnight before the examination. The fee is £5 5*s.* The examination is conducted by specially qualified examiners appointed by the University. Candidates may enter for the whole examination at one period or they may enter for Part I. at one period and for Part II. at another and subsequent period.

*The Royal Colleges of Surgeons and Physicians of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow.*—All candidates for the Diploma in Public Health must have been qualified for at least one year. Those qualified before 1890 and also those who have held the position of medical officer of health to a county or to an urban district of more than 20,000 inhabitants, or an entire rural sanitary district, do not require to produce evidence of attendance on any special courses. All other candidates must have attended, after qualifying, six months' practical instruction in a recognised public health laboratory or laboratories, and must have studied for six months the duties of outdoor sanitary work under the medical officer of health of a county or large urban district, or must themselves have held an appointment as medical officer of health under conditions not requiring the possession of a sanitary diploma. It is also recommended where possible to take out a course of instruction in the diseases of animals transmissible to man. There are two examinations, and candidates may enter for both at one period or for either separately. The First Examination includes (*a*) Laboratory Work, (*b*) Chemistry, (*c*) Physics, and (*d*) Meteorology; and the Second Examination embraces (*a*) Report on Premises visited, (*b*) Examination at Fever Hospital, (*c*) Examination at Public Abattoir, (*d*) Epidemiology and Endemiology, (*e*) Vital Statistics and Sanitary Law, and (*f*) Practical Sanitation. The fee is 12 guineas for both examinations, or 6 guineas for either of them. A fee of £3 3*s.* is payable by rejected candidates to either examination. The examination is held twice yearly in May and October. The published regulations provide detailed synopses of the subjects of examination and give lists of books from which to select. The Registrar for Edinburgh is Mr. James Robertson, solicitor, 43, George-square, and for Glasgow Mr. Alexander Duncan, LL.D., 242, St. Vincent-street.

### IRELAND.

*Royal University of Ireland.*—This University grants a Diploma in Sanitary Science. It is conferred only on graduates in Medicine of the University. Candidates are not admitted to this examination until the lapse of twelve months from the time of obtaining the first registrable qualification; they must give notice in writing to the Secretaries of their intention to present themselves and must pay the fee, £2 at least one month previously to the examination. Candidates are required to produce a certificate of having, *after obtaining the degree of M.B., B.Ch., B.A.O.*, attended six months' practical instruction in a laboratory approved by the University, and also of having for six months practically studied the duties of outdoor sanitary work under the Medical Officer of Health of a county or large urban district. Candidates at this examination must answer in the following subjects. (1) Physics, (2) Climatology, (3) Chemistry, (4), Microscopy, (5) Bacteriology, (6) Geology, (7) Sanitary Engineering, and (8) Hygiene, Sanitary Law, and Vital Statistics.

*University of Dublin.*—The Diploma in Public Health is conferred, after examination, on the following conditions:—The candidate must be a Doctor in Medicine or a graduate in Medicine and Surgery of Dublin, Oxford, or Cambridge. The name of the candidate must have been on the Medical Register at least twelve months before the examination. The candidate must have completed (unless registered as a practitioner on or before Jan. 1st, 1890), subsequently to registration, six months' practical instruction in a laboratory approved by the University and also have studied practically outdoor sanitary work for six months, under an approved officer of health. The subjects of examination will be—(*a*) State Medicine and Hygiene, including causation and prevention of disease, contagion in different diseases morbid diathesis, congenital diseases and malformations, diseases of animals in relation to the health of man, diseases of the vegetable kingdom, famine diseases, causes of origin and spread of epidemics, principles of bacteriology, quarantine, disinfection, &c.; (*b*) Chemistry, including air, water, and articles of food and drink, and their chemical and microscopical examination and analysis, the detection of common poisons and recognition of injurious pigments, &c.; (*c*) Physics and Meteorology; (*d*) Engineering; (*e*) Morbid Anatomy; (*f*) Vital Statistics; (*g*) Medical Jurisprudence; (*h*) Practical Sanitary Engineering, Epidemiology, and Duties of a Public Health Officer; and (*i*) Law.

*Royal College of Physicians and Royal College of Surgeons in Ireland.*—Stated examinations for the Diploma in State Medicine are held in the months of February, May, and November. A special examination for the diploma can be (except during the months of August and September) obtained on payment of £10 10*s.*, in addition to the ordinary fees mentioned below, and on giving notice at least one fortnight before the date of the proposed examination. Every candidate for the Diploma in State Medicine must be a registered medical practitioner. (Candidates registered or entitled to be registered prior to January, 1890, are

exempt from the rules as to study.) He must subsequently to qualification (1) receive six months' laboratory instruction in Chemistry, Bacteriology, and the Diseases of Animals transmissible to man; and (2) during six months either practically study outdoor sanitary work under a medical officer of health or himself hold an appointment of medical officer of health under conditions not requiring the possession of a special sanitary diploma, and shall as an additional requirement attend a hospital for infectious diseases, unless this has been already done during his ordinary medical course. Candidates are examined on four days commencing on the first Tuesday of February, May, and November. Each candidate must return his name to the secretary of the Committee of Management under the Conjoint Scheme three weeks before the examination, and lodge with him a testimonial of character from a Fellow of either of the Colleges, or of the Royal Colleges of Physicians or Surgeons of London or Edinburgh. The fee for the examination is £10 10s. The examination for the diploma in State Medicine comprises the following subjects:—State Medicine and Hygiene, Chemistry, Meteorology and Climatology, Engineering, Vital Statistics, Law and Bacteriology. For further particulars apply to the Secretary, Committee of Management; Office, Royal College of Physicians, Dublin.

## DENTAL SURGERY.

ANYONE who is on the Medical Register is entitled to practise as a dentist, although he cannot register as such without the special licence; but it is of eminent advantage to take the L.D.S., otherwise few dental appointments at general or special hospitals or dispensaries are available, and, what is still more important, the manual dexterity and knowledge of mechanics requisite for the successful practice of dentistry can only be gained by long and careful training at the dental operating chair and in the dental laboratory; and, this having been attained, it costs but little trouole to pass the special examinations. The subjects beyond those included in the general qualification are—Dental Anatomy and Physiology (Human and Comparative), one course; a separate course of Dental Histology, including the preparation of microscopical sections; Dental Surgery, one course; a separate course of Practical Dental Surgery; a course of not less than five lectures on the Surgery of the Mouth; Dental Mechanics, one course; a course of Practical Dental Mechanics, including the manufacture and adjustment of six dentures and six crowns; Dental Metallurgy, one course; a course of Practical Dental Metallurgy; Practice of Dental Surgery at a recognised school, two years, and a certificate of having been engaged during a period of not less than three years in acquiring a knowledge of Dental Mechanics (this may be obtained by apprenticeship to a duly qualified dental practitioner or in the mechanical department of a recognised dental hospital). In the case of qualified surgeons two years will suffice. The Dental Schools in London are the Dental Hospital of London, the National Dental Hospital and College, and Guy's Hospital Dental School. Most of the large provincial towns have now dental hospitals. A convenient arrangement by which the M.R.C.S., L.R.C.P., and L.D.S. can be taken is as follows:—The Preliminary Examination in General Education having been passed the student should become apprenticed to a qualified dentist and register as a dental and medical student. (This instruction, however, may be taken prior to the date of registration as a dental student.) During his apprenticeship the student should receive instruction in Chemistry and Physics, Pharmacy and Elementary Biology, and pass in these subjects before entering the hospital. (The foregoing constitute the First Examination.) Having entered the hospital the student should attend the dental and general courses contemporaneously, and pass at the end of the second winter the Second Examination—namely, Anatomy and Physiology. At the completion of his second year of study the Dental Examination should be passed. The student should then devote his time to general studies and pass the Third Examination. When time permits it is advisable to attend the general hospital only until after the First and Second Examinations have been passed. At this point a break may be made to admit of the completion of the dental curriculum and the passing of the examinations for the L.D.S. diploma. The best course, ho vever, is to entirely finish the curriculum for the M.R.C.S. and L.R.C.P. and then take the special Dental work. The regulations for the Dental Licence of the Royal Colleges of Ireland and Edinburgh and of the Faculty of Physicians and Surgeons of Glasgow are very similar to those of the English College. The L.D.S. can also be obtained alone.

### REGISTRATION OF DENTAL STUDENTS.

The registration of dental students is carried on at the Medical Council Office in London in the same manner as the existing registration of medical students, and subject to the same regulations as regards Preliminary Examinations. Students who commenced their professional education by apprenticeship to dentists entitled to be registered or by attendance upon professional lectures before July 22nd, 1878 (when dental education became compulsory), are not required to produce evidence of having passed a Preliminary Examination. Candidates for a diploma in Dental Surgery must produce certificates of having been engaged during four years in professional studies and of having received three years' instruction in mechanical dentistry from a registered practitioner. One year's *bonâ-fide* apprenticeship with a registered dental practitioner, after being registered as a dental student, may be counted as part of the four years of professional study. The three years of instruction in mechanical dentistry, or any part of them, may be taken by the dental student either before or after his registration as a student, but no year of such mechanical instruction will be counted as one of the four years of professional study unless taken after registration.

It is now necessary for anyone practising Dental Surgery in this country to register and no foreign qualifications are admitted. Formerly exception was made with regard to the Universities of Harvard and Michigan.

*The Royal College of Surgeons of England* grants a diploma in Dental Surgery under the following regulations, which apply to all candidates who have registered as dental students after Jan. 1st, 1897. Candidates are required to pass three examinations: the Preliminary Science Examination, the First Professional Examination, and the Second Professional Examination. I. Preliminary Science Examination.—Before admission to this examination the candidate must produce a certificate of having received instruction (which may be taken prior to the date of registration as a dental student) at a recognised institution in Chemistry, Physics, and Practical Chemistry. The examination consists of these subjects and is identical with Part I. of the First Examination of the Examining Board in England. II. The First Professional Examination.—The candidate must produce the following certificates: 1. Of having been engaged during a period of not less than three years in acquiring a practical familiarity with the details of mechanical dentistry, under the instruction (which may be taken prior to registration as a dental student) of a competent practitioner or under the direction of the superintendent of the mechanical department of a recognised dental hospital. In the case of qualified surgeons evidence of a period of not less than two, instead of three, years of such instruction will be sufficient. 2. Of registration as a dental student by the General Medical Council. 3. Of having attended at a recognised Dental Hospital and School (*a*) a course of lectures on Dental Metallurgy; (*b*) a course of Practical Dental Metallurgy; (*c*) a course of Lectures on Dental Mechanics; and (*d*) a course of Practical Dental Mechanics, including the manufacture and adjustment of six dentures and six crowns. Candidates may present themselves for the First Professional Examination after the completion of six months' attendance at a recognised Dental Hospital and School. The Examination consists of Mechanical Dentistry and Dental Metallurgy; the examination in Dental Metallurgy will be by written paper. III. The Second Professional Examination—The candidate must produce the following certificates: 1. Of having been engaged during four years in the acquirement of professional knowledge subsequently to the date of registration as a dental student. 2. Of having attended at a recognised dental hospital and school (*a*) a course of Dental Anatomy and Physiology; (*b*) a separate course of Dental Histology, including the preparation of microscopical sections; (*c*) a course of Dental Surgery; (*d*) a separate course of Practical Dental Surgery; and (*e*) a course of not less than five lectures on the Surgery of the Mouth, which lectures may be given at a dental hospital or at a recognised medical school; in the latter case they may form part of the course of lectures on Surgery. 3. Of

having attended at a recognised dental hospital or in the dental department of a recogised general hospital the practice of Dental Surgery during two years. 4. Of having attended at a recognised medical school (*a*) a course of lectures on Anatomy, (*b*) a course of lectures on Physiology, (*c*) a separate Practical Course of Physiology, (*d*) a course of lectures on Surgery, and (*e*) a course of lectures on Medicine. 5. Of having performed Dissections at a recognised medical school during not less than twelve months. 6. Of having attended at a recognised hospital the practice of Surgery and Clinical Lectures on Surgery during two winter sessions. 7. Of being twenty-one years of age. The certificates of professional study will be required to show that students have attended the courses of professional study to the satisfaction of their teachers. Candidates may present themselves for the Second Professional Examination after the completion of four years' professional study from the date of registration as a dental student and after the lapse of not less than six months from the date of passing the First Professional Examination. The Second Professional Examination consists of General Anatomy and Physiology, General Surgery and Pathology, Dental Anatomy and Physiology, Dental Pathology and Surgery, and Practical Dental Surgery. The written examination comprises General Anatomy and Physiology, General Pathology and Surgery, Dental Anatomy and Physiology, and Dental Pathology and Surgery. At the Practical Examination candidates may be examined (*a*) on the treatment of Dental Caries, and may be required to prepare and fill cavities with gold or plastic filling or material, or to do any other operation in Dental Surgery (candidates must provide their own instruments); (*b*) on the Mechanical and Surgical Treatment of the various irregularities of Children's Teeth. There is also an Oral Examination. Exemption from the Preliminary Science Examination is granted to candidates who have passed an Examination in Chemistry and Physics for a degree in Medicine at a University in the United Kingdom, in India, or in a British colony. Exemption from Examination in Anatomy and Physiology is granted to candidates who have passed the Second Examination of the Examining Board in England or the corresponding Examination of the Royal College of Surgeons of Edinburgh, of the Royal College of Surgeons in Ireland, or the Faculty of Physicians and Surgeons of Glasgow, or of any University in the United Kingdom. Exemption from Examination in General Surgery and Pathology is granted to candidates who have passed the Examination in Surgery of the Examining Board in England or the corresponding Examinations of the Colleges and Universities above mentioned. The fee for the diploma is 20 guineas and is payable as follows:—Preliminary Science Examination, 3 guineas; First Professional Examination, 2 guineas; Second Professional examination, 5 guineas; the balance to be paid on the completion of the Examinations. The Preliminary Science Examination is held in January, March or April, July, and October in each year. The First and Second Professional Examinations are held in May and November in each year. Candidates must give twenty-one clear days' notice of their intention to present themselves for examination.

*Royal College of Surgeons, Edinburgh.*—For the Licence in Dental Surgery all candidates must pass a Preliminary Examination in General Knowledge and have their names inscribed in the Register of Dental Students of the General Medical Council. A copy of regulations, giving a list of Preliminary Examinations recognised for obtaining this Licence, as well as of the subjects of the Professional Examinations, may be obtained from Mr. James Robertson, Clerk to the Royal College of Surgeons, at 48, George square, Edinburgh. Students who commenced their professional education by apprenticeship or attendance on lectures before July 22nd, 1878, are exempt from the Preliminary Examinations. Candidates must produce certificates of having, subsequently to the date of registration, been engaged for four years in professional studies and of three years' instruction in Mechanical Dentistry from a registered dental practitioner, except in the case of previously registered medical practitioners, when two years will be considered sufficient. Candidates who have commenced their studies *after* Oct. 1st, 1890, must have attended the following curriculum: Anatomy, one course of six months; Practical Anatomy, twelve months; Chemistry, one course of six months; Practical Chemistry, one course of three months; Physiology, one course of six months; Materia Medica, one course of three months; Surgery, one course of six months; Medicine, one course of six months; and attendance on the practice of a recognised general hospital, with Clinical Instruction, twelve months. (Candidates who commenced study in accordance with the regulations in force before July, 1895, shall not be required to attend more than six months' hospital work.) These courses must have been attended at a University or in an established school of medicine or in a provincial school specially recognised by the College as qualifying for the diploma in Surgery. In addition to these courses candidates will be required to have attended in a recognised dental hospital, or with teachers recognised by the College, the following special courses of lectures and instruction: Dental Anatomy and Physiology (Human and Comparative) (not less than 24 lectures), Dental Surgery and Pathology (not less than 20 lectures), Dental Mechanics (not less than 12 lectures)—one course each; two years' attendance at a dental hospital or the dental department of a general hospital recognised by the College. Certificates of attendance on such of these courses of the new curriculum as may be respectively required will entitle candidates to appear either for the First Dental Examination or for the First and Second Examinations for the Triple Qualification, as they may select, and subject to the existing regulations for each qualification. Candidates who have passed the First and Second Examinations for the Triple Qualification will be exempt from the First Dental Examination and will have the advantage of being admissible either to the Final Dental Examination or to the subsequent Examination for the Triple Qualification, or to both. But the First Dental Examination will not be held as equivalent to the First and Second Triple Examinations and will admit to the Final Dental Examination only. Candidates who are Licentiates of this College or who may be registered medical practitioners will be required to produce certificates of attendance on the special subjects only and will be examined in these only for the dental diploma. First Professional Examination: The candidate must have attended the courses on Anatomy, Chemistry, and Physiology. The examination embraces Anatomy, Chemistry and Physiology. The fee is £4 4*s*. Second Examination: The candidate must have attended the remaining courses of the curriculum, must produce certificates showing that he is twenty-one years of age, and must pay a fee of £6 6*s*. The examination embraces Surgery, Medicine, Therapeutics, and the special subjects of Dental Anatomy and Physiology, Dental Surgery and Pathology, and Dental Mechanics with Dental Metallurgy. Unsuccessful candidates will be repaid £2 2*s*. in the First and £3 3*s*. in the Second Examinations. Candidates who claim exemption from the First Dental Examination on the ground of having passed the First and Second Triple Qualification Examinations will, before being admitted to the Second Dental Examination, be required to pay the total fee of £10 10*s*. payable for the dental diploma, of which £3 3*s*. will be returned in case of rejection. The fee payable by candidates who begin study after Oct. 1st, 1896, shall be £15 15*s*.

*Faculty of Physicians and Surgeons of Glasgow.*—The regulations as to certificates, curriculum, number, and subjects of examinations, fees, &c., are in effect similar to those of the Royal College of Surgeons of Edinburgh. Special provision is made for candidates who intend to qualify both in Medicine and in Dentistry. There is a practical examination in Mechanical Dentistry and also an examination in Practical Dentistry conducted in a dental hospital.

*Royal College of Surgeons in Ireland.*—All information concerning the licence in Dentistry may be obtained from the Registrar of the College, who will receive the applications of candidates for permission to be examined. The bank receipt for fees, together with all certificates, &c., are to be lodged with him at least seven days prior to the day fixed for the commencement of the examination. The Primary Dental Examinations commence on the second Monday in the months of February, May, and November. The Final Dental Examinations commence on the Thursdays immediately following the Primary Dental Examinations. Candidates are required to pass three examinations—viz., Preliminary (in General Education), Primary Dental, and Final Dental. Preliminary Examination.—All examinations in general education recognised by the General Medical Council are accepted by the College. Preliminary Examinations are held conjointly by the Royal Colleges of Physicians and Surgeons on the third Wednesdays in March and September. Primary Dental

Examination.—Fee £10 10*s.*; for re examination, if rejected, £5 5*s.* Every candidate[1] is required, before admission to the Primary Dental Examination, to produce evidence—(1) of having passed a recognised preliminary examination and of having been registered as a medical or dental student by the General Medical Council; (2) of having, subsequently to registration as a dental or medical student, attended at a recognised medical school the following courses: Lectures on Practical Anatomy, including Dental Anatomy, six months; Demonstrations and Dissections, two courses of six months each; Lectures on Chemistry, six months; Lectures on Physiology, including Dental Physiology, six months; Practical Histology; and Practical Chemistry, including Metallurgy, three months; (3) of having attended Clinical Instruction at a recognised general hospital for one year. The subjects of this examination are: (1) Physics;[2] (2) Chemistry, including Metallurgy; (3) Anatomy; (4) Physiology and Histology; and (5) Surgery. Final Examination.—Candidates holding L.R.C.S.I. or students who have passed Primary Dental or Third Professional Examination of the College, £10 10*s*; re-examination, £5 5*s*. Fees for Final Examination of all other candidates, £26 5*s*.; re-examination, £10 10*s*. Extra fee for Special Examination, £5 5*s*. Candidates must produce evidence of having passed the Primary Dental Examination of this College, or the Third Professional Examination under the Conjoint Board with the Royal College of Physicians in Ireland, or with the Apothecaries' Hall, or an equivalent examination recognised by the College, and are required to produce certificates of having attended: (1) the following courses of lectures recognised by the College: Dental Surgery and Pathology (two courses), Dental Mechanics (two courses); (2) for two years the practice of a dental hospital recognised by the College or of the dental department of a general hospital so recognised; (3) of having been engaged during four years in professional studies; and (4) of having received three years' instruction in Mechanical Dentistry from a registered dentist. Candidates holding a diploma in Surgery shall be admissible to the Final Dental Examination on producing certificates of having attended: (1) one course of Lectures on Dental Surgery and Pathology; (2) one course of Lectures on Dental Mechanics; (3) for one year the practice of a dental hospital recognised by the College, or of the dental department of a general hospital so recognised, where such attendance has been subsequent to the date of diploma (this remission (3) has been made on the understanding that the surgeon devotes his whole time to dental work); and (4) of having been engaged during a period of not less than two years in acquiring a practical familiarity with the details of Mechanical Dentistry under the instruction of a registered dentist. The following are the subjects of examination: Dental Surgery, Theoretical (including Dental Pathology), Clinical, and Operative; Dental Mechanics, Theoretical, Clinical, and Practical (including the Metallurgy of the Workshop). Examinations for the Licence in Dentistry *sine curriculo:* The Council has power to admit to examination, *sine curriculo*, candidates whose names are on the Dental Register published under the direction of the General Medical Council, and who are unable to furnish the certificates required by the foregoing regulations, on presentation of a special schedule of application.

## TEACHING INSTITUTIONS.

### ENGLAND.

*Dental Hospital of London and School of Dental Surgery, Leicester-square.*—The school provides the special dental education required by the Royal College of Surgeons for the Licence in Dental Surgery. The general part of the curriculum may be taken at any general hospital. The hospital is open from 9 A.M. to 4 P.M., there being one staff for the morning and another for the afternoon of each day. Pupils are received for the three years' mechanical training recognised by the curriculum. The demonstrators at the commencement of each session give a course of lectures on Operative Dental Surgery. The eight house surgeoncies are held for one year each, and are open to all qualified students. The lecturers in addition to their lectures, give special demonstrations on the Microscopy of Dental Anatomy and Dental Surgery. The lecturer on Dental Mechanics also gives practical demonstrations in the mechanical laboratory. Two scholarships of the value of £20 have been founded by Sir Edwin Saunders and Dr Joseph Walker. Prizes and certificates are awarded by the lecturers for the best examinations in the subjects of their respective courses, at the end of the summer and winter sessions. A prize of the value of 5 guineas is given by Messrs. Ash and Sons for the best essay on some surgical subject connected with Dental Surgery. The conditions under which this prize is to be competed for are the same as those for the Saunders Scholarship, with this exception, that the papers are to be written in the hospital during the summer session. Consulting Physician: Sir Richard Douglas Powell, Bart., M.D. Consulting Surgeon: Mr. Christopher Heath, F.R.C.S. Consulting Dental Surgeons: Mr. T. Arnold Rogers, M.R.C.S., L.D.S., and Mr. Smith Turner, M.R.C.S., L.D.S. Dental Surgeons: Leonard Matheson, L.D.S.; E. Lloyd Williams, L.R.C.P., M.R.C.S., L.D.S., L.S.A.; W. B. Paterson, F.R.C.S., L.D.S.; W. H. Woodruff, L.D.S.; A. Clayton Woodhouse, M.R.C.S., L.D.S.; and J. F. Colyer, L.R.C.P., M.R.C.S., L.D.S. Assistant Dental Surgeons: C. F. Rilot, L.R.C.P., M.R.C.S., L.D.S.; H. Lloyd Williams, M.R.C.S., L.D.S.; W. H. Dolamore, L.R.C.P., M.R.C.S., L.D.S.; G. Hern, L.R.C.P., M.R.C.S., L.D.S.; J. G. Turner, L.R.C.P., F.R.C.S., L.D.S.; Russell Barrett, L.R.C.P., M.R.C.S., L.D.S.; N. G. Bennett, M.A., M.B., B.C., L.R.C.P., M.R.C.S., L.D.S.; D. P. Gabell, L.R.C.P., M.R.C.S., L.D.S.; and W. J. May, L.R.C.P., M.R.C.S., L.D.S.; A. Hopewell Smith, L.R.C.P., M.R.C.S., L.D.S.; W. S. Nowell, M.A., L.R.C.P., M.R.C.S., L.D.S. Anæsthetists: Dudley W. Buxton, M.D., B.S. Lond., M.R.C.P. Lond.; Frederic W. Hewitt, B.A., M.D. Cantab.; Carter Braine, F.R.C.S.; Henry Davis, M.R.C.S., L.S.A.; George Rowell, F.R.C.S.; and E. A. Bridger, M.D. Assistant Anæsthetists: R. Turle Bakewell, M.B. Lond., L.R.C.P., M.R.C.S.; R. J. Probyn-Williams, M.D. Durh.; H. Bellamy Gardner, L.R.C.P., M.R.C.S.; George Flux, M.D. Brux.; H. J. Paterson, M.A., M.B., B.C. Cantab., F.R.C.S. Demonstrators: H. Austin, M.D. Lond., L.D.S.; R. Herschell, L.D.S.; and R. McKay, L.R.C.P., M.R.C.S., L.D.S.; and H. E. Cribb, L.D.S. Medical Tutor: W. S. Nowell, M.A. Oxon., L.D.S. Curator of Mechanical Laboratory: W. E. Fletcher. Lecturers.—Dental Anatomy and Physiology (Human and Comparative): Charles Tomes, F.R.S., M.A. Oxon., F.R.C.S., L.D.S., assisted by Mr. Hopewell Smith in Dental Histology. Dental Surgery and Pathology: W. Hern, L.R.C.P., M.R.C.S., L.D.S., assisted by Mr. R. Herschell. Mechanical Dentistry: E. Lloyd Williams, L.R.C.P., M.R.C.S., L.D.S., L.S.A. Metallurgy in its Application to Dental Purposes: Dr. Forster Morley, M.A., F.I.C., F.C.S., assisted by Mr. H. Richards. During the sessions the surgeons of the day will give demonstrations at stated hours. The house surgeons attend daily while the hospital is open. Fee for two years' hospital practice required by the curriculum, including lectures, £50 in one payment, or 50 guineas in two yearly instalments. The curriculum requires two years to be passed at a General Hospital; the fee for this is about £55. Both hospitals can be attended simultaneously. The Dean, Mr. Morton Smale, attends at the hospital every Wednesday morning from 10 to 12, or he can be seen at other times by appointment. Letters to be addressed—The Dean, 40, Leicester-square, "to be forwarded."

*National Dental Hospital and College.*—Winter Session, 1900–1901, commences on Oct. 1st at the new building at the corner of Great Portland and Devonshire-streets, W.—Consulting Physician: Sir W. H. Broadbent. Consulting Surgeon: Mr. Christopher Heath. Consulting Dental Surgeon: Sir Edwin Saunders. Visiting Physician: Dr. James Maughan. Visiting Surgeon: Mr. E. W. Roughton. Dental Surgeons: Mr. F. H. Weiss, Mr. A. Smith, Mr. M. Davis, Mr. T. G. Read, Mr. Rushton, and Mr. C. W. Glassington. Assistant Dental Surgeons: Mr. W. Weiss, Mr. E. Beverley, Mr. S. F. Rose, Mr. A. E. Relph, and Mr. H. J. Relph. Anæsthetists: Mr. H. P. Noble, Mr. C. E. A.

[1] Candidates educated in England or Scotland are admitted to the Primary Dental Examination on the production of the certificates that would be necessary for both Primary and Final Examinations in their own countries.

[2] Candidates who have passed in Chemistry and Physics at a First Professional Examination under the Conjoint Board with the Royal College of Physicians in Ireland, or with the Apothecaries' Hall, or an equivalent examination recognised by the College, are exempted from examination in these subjects at the Primary Dental Examination.

Macleod, Mr. C. J. Ogle, Mr. G. E. Norton, Dr. J. Maughan, and Dr. Harold Low. Lecturers (winter), Dental Anatomy and Physiology: Dr J. W. Pare, Tuesdays and Thursdays, 5 P.M., in October, November, and December. Dental Metallurgy: Dr. A. B. Griffiths, Tuesdays, 5.45 P.M., in January, February, and March. Dental Mechanics: Mr. H. Rose, Wednesdays, 6 P.M., in January, February, and March. Summer—Dental Surgery and Pathology, Mr. H. J. Relph, Tuesdays and Fridays, 6 P.M., in May, June, and July. Surgery of the Mouth: Mr. E. W. Roughton, Mondays at 5, May, June, and July. Practical courses to comply with the R.C.S. curriculum are also held. The hospital is lighted throughout by electricity and warmed and ventilated by approved methods. Clinical Lectures and Demonstrations are given from time to time, and each student on entering passes through a preliminary course under a demonstrator. The stopping rooms have accommodation for sixty chairs. Dresserships in the extraction and stopping rooms are re-arranged every three months. An Entrance Exhibition, of the value of £15, is open for competition at the commencement of each summer and winter session. Prizes in medals are open for competition at the end of each course of lectures. Certificates of honour are given in each class. The Rymer Medal for General Proficiency, value £5, is awarded annually to the most meritorious student; and the Ash Prize, value £3 3*s.*, for a Thesis on a subject in Dental Surgery. Total fee for the Special Lectures and Hospital Practice required, 40 guineas. Single Courses: Dental Anatomy and Physiology, Dental Surgery and Pathology, Dental Mechanics, Dental Metallurgy, Dental Materia Medica, Demonstration of Dental Mechanics, £5 5*s.* each. Hospital Practice to registered practitioners by special permission of Committee, twelve months, £15 15*s.* The Committee also consider applications from medical men who may desire to attend the Anæsthetic Room for a course of instruction in Nitrous Oxide administration. Information respecting the Hospital Practice and the College may be obtained from the Dean, Mr. Sidney Spokes, who attends at the Hospital, Great Portland-street, on Tuesday mornings.

*Guy's Hospital.*—The work of the Dental Department begins daily at 9 A.M. both in the extraction rooms and in the conservation room. *The Extraction Rooms:* Patients are admitted between 9 and 9.30 A.M., and are seen by the dental surgeon for the day, the dental house surgeon, the assistant dental house surgeon, and the dressers. Such cases as are suitable for conservative treatment are transferred to the conservation room, taking with them a dental chart to indicate the treatment required. *The Conservation Room:* This room is open from 9 A.M. till 5 P.M. There are 55 Morrison chairs for the use of the Dressers, who, under the supervision of the Staff, perform the various operations of Dental Surgery. The members of the staff attend every morning and afternoon in the week to give demonstrations and otherwise assist students in their work in the Conservation Room and Mechanical Laboratory. Dental students have the opportunity of attending concurrently at this hospital the two courses of instruction required by the examining board for the L.D.S. Eng., viz., the special lectures and practice of the Dental Department and the general lectures and practice of the Medical School. The fees for these two courses may be paid separately or together, or they may be combined with the fees required to be paid for the course for a medical diploma. Students who enter for a medical as well as a dental diploma are allowed to pursue their study of Dentistry during any period of their medical course most convenient to themselves without further charge. An Entrance Scholarship[3] in Arts of the value of £30 is offered for competition annually in September, and prizes of the aggregate value of £35 are awarded for general proficiency and skill in Practical Dentistry. Dental students are eligible for admission to the Residential College and enjoy the other social privileges of students in the Medical School.

*London Hospital.*—Mr. Dolamore and Mr. Farmer give practical instruction during the winter and summer sessions on Mondays, Tuesdays, Thursdays, and Fridays at 9 A.M. In selecting from candidates for the office of Dental Assistant priority will be given to those who have attended the greatest number of lectures on Dental Pathology and Surgery, and have also been the most punctual in attendance in the dental department. A class for special instruction in filling teeth will be formed each term. Candidates for Dressership must undertake to attend regularly on Mondays and Thursdays, or on Tuesdays and Fridays, for three months, and to follow the practical course of demonstrations.

*University of Birmingham.*—The teaching of Dentistry is undertaken by the University acting in association with the Birmingham Dental Hospital and the Birmingham Clinical Board, so that the students may fully qualify themselves for the Dental diploma of the Royal Colleges. There is a special and well-equipped Dental Museum and Laboratory. An Entrance Exhibition, value £37 10*s.*, is awarded annually at the commencement of the winter session. Medals and honour certificates are awarded annually in the various classes. The following are the regulations for Degrees in Dentistry:—1. The degrees conferred by the University are those of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.). 2. All candidates for these degrees must pass the same Matriculation Examination as that required from candidates for Medical Degrees. 3. The degree of Bachelor of Dental Surgery is not conferred upon any candidate who has not obtained a Licence in Dental Surgery from some body legally entitled to confer such qualification. The candidate is not eligible for the degree until a period of 12 months has elapsed from the passing of his examination for the Licence in Dental Surgery. Of this period at least six months must be spent in the dental department of a general hospital approved by the University. 4. *A.* In addition to the Licence in Dental Surgery the candidate must produce evidence that he has attended the Courses required by medical students of the University in the following subjects and passed the Examinations held in the same for Medical and Surgical Degrees: (*a*) Chemistry and Practical Chemistry, (*b*) Physics and Practical Physics, (*c*) Biology, (*d*) Anatomy and Practical Anatomy, and (*e*) Physiology and Practical Physiology. *B.* That he has attended the following Courses: (*f*) One Course of Lectures on Medicine, (*g*) One Course of Lectures on Surgery, (*h*) Special Courses of Lectures on the Surgery and Medicine of the Mouth, and (*i*) Pathology and Bacteriology, and has passed the examinations for candidates for Dental Degrees held in each of these subjects: *C.* That he has attended Courses in: (*k*) Dental Histology and Patho-Histology, (*l*) Comparative Dental Anatomy, and (*m*) Dental Surgery and Prosthetic Dentistry. *D.* That he has received instruction in the Clinical Examination of living cases at the dental department of a general hospital for a period not less than six months. 5. The Final Examination will deal with the subjects in Classes *C.* and *D.* 6. On the expiration of 12 months from the date of passing the Examination for the Degree of Bachelor of Dental Surgery, the candidate will be eligible for that of Master of Dental Surgery. 7. For this degree candidates will be required to submit a thesis containing original work and investigations in some subject connected with Dentistry, which thesis shall be submitted to examiners to be nominated by the Board of Dental Studies. The degree will be awarded or withheld according to the report of these examiners.

*University College, Bristol.* — Dental students can enter for the full curriculum at Bristol. The Lectures are delivered at the college. Practical instruction is given at the *Royal Infirmary* by Mr. Ackland and at the *General Hospital* by Mr. Genge, both institutions being recognised by the Dental Board of the Royal College of Surgeons of England. Full information may be obtained of the Dean of the Medical Faculty, Professor E. Markham Skerritt, University College, Bristol.

*Owens College, Manchester* —Arrangements have been made for dental students to attend the hospital practice at the Manchester Royal Infirmary and the practice at the Victoria Dental Hospital. Lectures on special subjects will be given in the College as follows:—Winter session: Dental Mechanics, Mr. Tanner, Thursday, 4 P.M. Dental Metallurgy, Mr. J. P. Headridge, Monday, at 3.30 P.M. Summer session: Dental Anatomy and Physiology, Dr. Preston, Tuesday at 4 P.M., Friday at 2 P.M. Dental Surgery, Mr. Campion, Tuesday and Friday, 3 P.M. Practical and Operative Dental Surgery, Mr. Whittaker, Wednesday: Lecture, 2.30 P.M.; Demonstration, 4 P.M. Lectures in Dental Histology, Mr. D. Headridge, Monday, at 2 P.M. Fee for each course £4 4*s.* for the Class in Practical

[3] In Sept., 1901, a scholarship of the same value in Dental Mechanics will be substituted. A Dental Travelling Scholarship of the value of £100 has been founded. The next award will be made in June, 1902.

Metallurgy, £2 2s. Dental practice for two years at the Manchester Royal Infirmary, £10 10s.; at the Victoria Dental Hospital at Manchester, £21, paid in advance, or £13 13s. for the first year and £8 8s. for the second year. At the Victoria Dental Hospital patients attend at 8.30 A.M. daily, and at 6.30 P.M. on Monday, Wednesday, and Friday. Consulting Physician: (vacant). Consulting Surgeon: Mr. J. Hardie. Consulting Dental Surgeon: Mr. H. Campion. Dental Surgeons: Mr. G. G. Campion, Mr. E. P. Collett, Mr. J. W. Dunkerley, Mr. W. Dykes, Mr. W. Headridge, Mr. W. A. Hooton, Mr. P. A. Linnell, Mr. F. W. Marshall, Mr. I. Renshaw, Mr. W. Simms, Mr. T. Tanner, and Mr. G. O. Whittaker. Assistant Dental Surgeons: Mr. H. T. Dreschfeld, Mr. D. Headridge, Mr. W. H. Norman, Mr. T. E. Sherratt, and Mr. C. H. Smale. Demonstrator: Mr. W. H. Jones. Tutor: Dr. C. H. Preston. Consulting Prosthetic Dental Surgeon: Mr. T. Tanner. Prosthetic Dental Surgeon: Mr. W. Nicholson. House Dental Surgeons: Mr. R. Howard and Mr. S. Kersh. Curator of Museum: Mr. D. Headridge. Administrators of Anæsthetics: Dr. A. Wilson, Mr. F. H. Westmacott, and Dr. W. B. Pritchard. Dean: Mr. William Simms.

*University College, Liverpool (Liverpool Dental Hospital and School of Dental Surgery).*—The courses of systematic instruction are given in University College, five minutes from the Dental Hospital. The two institutions are now closely associated and the management of the curriculum is in the hands of a joint committee. At the Dental Hospital recent alterations have been made and as it now stands this school offers advantages to students which are not excelled anywhere. The ground floor of the building contains the following: Extraction-room, with all needful appliances; anæsthetic room, specially reserved with every convenience; and large waiting-room for patients. The first floor has a large board-room and a very comfortable students' room set apart exclusively for the use of students. The whole top floor of the building has been thrown into one fine, airy, and well-ventilated operating room. This room will accommodate upwards of 30 operating chairs, which are of the "Morrison pattern," and each of which has a special electric light (canting pendant) suspended before it. In the basement a very convenient workroom has been fitted up containing the necessary requirements, and there are commodious lavatories for students. A new Laboratory for practical mechanical work was constructed last year, so as to meet the requirements of the curriculum. It is adequately furnished with all the modern appliances of a dental workshop. A skilled Dental Mechanic has been engaged and students are able to undertake at the hospital the whole of their training in Mechanical Dentistry. The times of the lectures at University College are arranged to meet the convenience of students, thus allowing the maximum time for attendance upon Dental Hospital practice. The staff of the hospital includes seven honorary Dental Surgeons, a Demonstrator, two House Surgeons, and a Curator. Fees for two years' hospital practice £21. Further information may be had from the Warden, Mr. W. H. Gilmour. The various medical and dental lectures are given at University College. The Anatomical Department contains an excellent collection of skulls illustrative of human and comparative dental anatomy. The dissecting-room and theatre are lighted by electricity. The Physiological and Pathological Departments are housed in new and spacious laboratories erected by the Rev. S. A. Thompson Yates. Fees: The composition fee for all lectures is £50 in one payment on entrance, or in two equal instalments (one-half on entrance and the remainder within twelve months). The fee for general hospital practice is £10 10s. Further particulars can be obtained of A. M. Paterson, M.D., Dean.

*Devon and Exeter Dental Hospital, Castle street, Exeter.*—Established 1880.—The hospital is open daily (Sundays excepted), and patients are admitted between the hours of 9 and 11 A.M. Students attending the practice of the hospital must consider themselves strictly under the control of the medical officers, and must not undertake any operation without the consent of the dental surgeon for the day. Hon. treasurer, Mr. J. M. Ackland; hon. secretary, Mr. Henry Yeo.

## SCOTLAND.

*The Incorporated Edinburgh Dental Hospital and School, 31, Chambers-street, Edinburgh.*—For the special classes, both theoretical and practical, required by dental students the directors have secured the services of an efficient staff of dental officers and lecturers. There will also be a course of demonstrations in Mechanical Dentistry. Students will receive instruction in Practical Dental Mechanics under the mechanician. The fee for clinics in gold filling is included in the Dental Hospital fee of £15 15s. The minimum cost of classes for the whole course of dental instruction amounts to £90 7s.

*Dental Hospital and School, Glasgow.*—The winter session will begin on Oct. 18th, and the lectures will be delivered as follows. In Dental Mechanics on Tuesday evenings, at 7.30 P.M., by Mr. Hugh McKay, L.R.C.S., L.R.C.P. Edin., L.F.P.S., L.D.S. and in Dental Metallurgy on Wednesday evenings at 7.30 P.M., by Professor T. R. Marshall, D.Sc. Ed., F.C.S. Fee for each of the above courses of lectures, £3 3s. The lectures and instruction at the Glasgow Dental Hospital and School are recognised by all the licensing bodies in the United Kingdom. The fees for two years' hospital practice are £15 15s. Intending students before commencing to attend the lectures or hospital practice must produce evidence of having passed the preliminary examination prescribed by the regulations of the General Medical Council for registration of dental students. The hospital is open daily from 5 to 7 P.M. (Saturdays excepted). Students may enrol either at the beginning of the winter or summer session.

*Glasgow Royal Infirmary* (Dental Department).—Mr. W. H. Gray, L.D.S., attends at the Royal Infirmary at 3 P.M. on Mondays, Wednesdays, and Saturdays, and gives a course of instruction in Dental Surgery on these days in summer. The following course in the curriculum can be taken at St. Mungo's College: Anatomy, six months; Practical Anatomy, nine months; Physiology, six months; Chemistry, six months; Practical Chemistry with Metallurgy, three months; Surgery, six months; Medicine, six months; Materia Medica, three months; Clinical Surgery, six months; Dental Surgery, six months, and attendance for two years on the dental department of the hospital. The attendance on the Dental Clinic is free to students of the hospital; to dental students, one year, £5 5s.; perpetual £10 10s. The winter session opens Thursday, Oct. 18th.

## IRELAND.

*Royal College of Surgeons in Ireland.*—The schools of surgery are attached by Charter to the Royal College of Surgeons and have existed as a department of the College for nearly a century. They are carried on within the College buildings and are specially subject to the supervision and control of the Council, who are empowered to appoint and remove the professors and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the dissecting-room nearly trebled, and special pathological, bacteriological, public health, and pharmaceutical laboratories fitted with the most approved appliances in order that students may have the advantage of the most modern methods of instruction. A refreshment-room is now open where students can have luncheon. There are special rooms set apart for lady students. The entire building is heated by hot-water pipes and lighted throughout by the electric light. Dentistry: Professor R. T. Stack, M.D. Univ. Dub., F.R.C.S., L.D.S. Eng., Examiner Royal College of Surgeons, Dentist, Dental Hospital of Ireland. Arrangements are completed for the education of candidates for the Licence in Dental Surgery of the College, and all the lectures of the Dental curriculum are delivered during the summer and winter sessions. All the lectures and courses of practical instruction may be attended by medical students who are otherwise unconnected with the College.

PRESENTATION TO A MEDICAL MAN.—At a meeting of the members of the Hertford Town Cricket Club held at the Dimsdale Hotel on August 8th Mr. J. T. Tasker-Evans, M.D. Aberd., was the recipient of a gold matchbox, in appreciation of the successful services he had rendered in connexion with the new Pavilion Fund by which £150 were raised. Dr. Tasker-Evans is a vice-president of the club and a resident in the town.

# SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY.

| INSTITUTION. | TITLE OF SCHOLARSHIP, &c. | ANNUAL OR TOTAL VALUE. | HOW LONG TENABLE. | HOW OBTAINABLE. | CONDITIONS ATTACHED TO TENURE. |
|---|---|---|---|---|---|
| LONDON UNIVERSITY .. | No. 1. | £40 per annum. | 2 years. | By first place with distinction in ANATOMY at July Intermediate M.B. Honours Examination. | M.B. Examination within 3 years. |
| | No. 2. | £40 per annum. | 2 years. | By first place with distinction in PHYSIOLOGY AND HISTOLOGY at July Intermediate M.B. Honours Examination. | Ditto |
| | No. 3. | £30 per annum. | 2 years. | By first place with distinction in ORGANIC CHEMISTRY at July Intermediate M.B. Honours Examination. | Ditto. |
| | No. 4. | £30 per annum. | 2 years. | By first place with distinction in MATERIA MEDICA and PHARMACEUTICAL CHEMISTRY at July Intermediate M.B. Honours Examination. | Ditto. |
| | University Scholarship in Medicine. | £50 per annum. | 2 years. | By first place with distinction in MEDICINE at M.B. Honours Examination. | |
| | University Scholarship in Obstetric Medicine. | £30 per annum. | 2 years. | By first place with distinction in OBSTETRIC MEDICINE at M.B. Honours Examination. | |
| | University Scholarship in Forensic Medicine. | £30 per annum. | 2 years. | By first place with distinction in FORENSIC MEDICINE at M.B. Honours Examination. | |
| | University Scholarship in Surgery. | £50 per annum. | 2 years. | By first place with distinction in B.S. Honours Examination. | |
| ST. BARTHOLOMEW'S MEDICAL SCHOOL | Entrance Scholarships. No. 1. | £75. | ... | Open Competitive Examination in not more than three nor fewer than two of CHEMISTRY, PHYSICS, ZOOLOGY, BOTANY, PHYSIOLOGY, ANATOMY. | Full Course at St. Bartholomew's Hospital. |
| | ,, No. 2. | £75. | ... | | Ditto. |
| | ,, No. 3 | £150. | ... | Open Competitive Examination in not fewer than three of the following :— CHEMISTRY, PHYSICS, BOTANY, ZOOLOGY, PHYSIOLOGY. | Ditto. |
| | Preliminary Scientific Exhibition. | £50. | ... | | Ditto. |
| | Jeaffreson Exhibition. | £20. | ... | Open Competitive Examination in LATIN, MATHEMATICS, and GREEK, FRENCH, or GERMAN. | Ditto. |
| | Shuter Scholarship. | £50. | .. | Competitive Examination among Cambridge Graduates in ANATOMY, PHYSIOLOGY, and MATERIA MEDICA. | Ditto. |
| | Junior Scholarships. | | | | |
| | ,, No. 1. | £30. | .. | Competitive Examination among Students in ANATOMY and BIOLOGY. | Study at St. Bartholomew's Hospital. |
| | ,, No. 2. | £20. | ... | Ditto. | Ditto. |
| | ,, No. 3. | £25. | ... | Competitive Examination in CHEMISTRY, PHYSICS, and HISTOLOGY. | Ditto. |
| | ,, No. 4. | £15. | ... | Ditto. | Ditto. |
| | Senior Scholarship. | £50. | ... | Competitive Examination among Students in ANATOMY, PHYSIOLOGY, and CHEMISTRY. | Ditto. |
| | Kirkes Scholarship. | £30 and Medal. | .. | Competitive Examination among Students in CLINICAL MEDICINE. | |
| | Brackenbury Scholarships. | | | | |
| | ,, No. 1. | £39. | .. | Competitive Examination among Students in MEDICINE. | Ditto. |
| | ,, No. 2. | £39. | ... | Competitive Examination among Students in SURGERY. | Ditto. |
| | Lawrence Scholarship. | £42 and Medal. | ... | Competitive Examination among Students in SURGERY, MEDICINE, and MIDWIFERY. | Ditto. |
| | Sir Geo. Burrows Prize. | £10 10s. | .. | Competitive Examination in PATHOLOGY among Students. | |
| | Skynner Prize. | £15. | ... | Competitive Examination in REGIONAL and MORBID ANATOMY among Students. | Ditto. |
| | Matthews Duncan Medal and Prize. | £20. | ... | Competitive Examination among Students in MIDWIFERY and GYNÆCOLOGY. | Ditto |
| | Research Studentship in Pathology. | £100. | ... | By Election, on the recommendation of the School Committee. | Research Work at St. Bartholomew's Hospital. |
| CHARING CROSS HOSPITAL AND COLLEGE | Entrance Scholarships, open to students at the commencement of curriculum. | | | | |
| | Livingstone. | 100 guineas. | .. | The Livingstone and Huxley Scholarships are awarded annually at the commencement of each Winter Session, after a competitive examination in the following groups of subjects : — (1) ENGLISH, including LANGUAGE, HISTORY, and GEOGRAPHY; (2) Any two of the following four languages —LATIN, GREEK, FRENCH, and GERMAN; (3) MATHEMATICS, | Open to all general students. |
| | ... | 60 ,, | ... | | Open to all general students. |

## SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY—*continued.*

| INSTITUTION. | TITLE OF SCHOLARSHIP, &c. | ANNUAL OR TOTAL VALUE. | HOW LONG TENABLE. | HOW OBTAINABLE. | CONDITIONS ATTACHED TO TENURE. |
|---|---|---|---|---|---|
| CHARING-CROSS HOSPITAL AND COLLEGE—*continued.* | Huxley. | 55 guineas. | .... | Including ARITHMETIC, ALGEBRA, and GEOMETRY; and MECHANICS, including STATICS and DYNAMICS; (4) INORGANIC CHEMISTRY and EXPERIMENTAL PHYSICS, including ACOUSTICS, HEAT, MAGNETISM, ELECTRICITY, and OPTICS; and (5) ANIMAL and VEGETABLE BIOLOGY. No Candidate may offer himself for examination in more than three of the above groups of subjects, the selection of the groups being left entirely to the Candidate. | For sons of medical men. |
| | ... | 40 ,, | .... | | Open to all general students. |
| | ... | 30 ,, | .... | | For dental students. |
| | Epsom Scholarship. | Free education. | .... | .... | Epsom Foundation Scholars who have passed Preliminary Scientific M.B. Lond. Univ. |
| | Universities Scholarship (1) | 60 guineas. | .... | Examination in ANATOMY and PHYSIOLOGY, including HISTOLOGY. | Oxford Students who have passed first M.B. Exam. |
| | Universities Scholarship (2) | 60 ,, | .... | | Cambridge students who have passed second M.B. Exam. |
| | | | | | London students who have passed Intermediate Exam. in Med. who have not entered at any London Medical School. |
| | Llewellyn Scholarship. | £25. | .... | Awarded annually to the Student of not more than five years' standing, who, in the opinion of the School Committee, shall have distinguished himself the most at the Prize Examinations in the following subjects, viz.:—MEDICINE, SURGERY, MIDWIFERY, PATHOLOGY, THERAPEUTICS, FORENSIC MEDICINE, PUBLIC HEALTH, PSYCHOLOGICAL MEDICINE, OPHTHALMOLOGY, PRACTICAL MEDICINE, PRACTICAL SURGERY, PRACTICAL MIDWIFERY. | None. |
| | Golding Scholarship. | £10. | .... | Competitive Examination among Second-year General Students in ANATOMY and PHYSIOLOGY, CHEMISTRY, and BIOLOGY. | Students must have attended the Classes in each subject at this School. |
| ST. GEORGE'S HOSPITAL. | Entrance Scholarships. No. 1. | £150. | .... | Competitive Examination among First-year Students, being the sons of medical men, in LATIN, GREEK, FRENCH, GERMAN, MATHEMATICS, PHYSICS, CHEMISTRY, and BIOLOGY; three at option. | Previous entrance at St. George's School. |
| | ,, No. 2. | £85. | .... | Competitive Examination among Students being First M.B.'s of Oxford or Second M.B.'s of Cambridge, in ORGANIC CHEMISTRY, ANATOMY, PHYSIOLOGY, ZOOLOGY, and BOTANY; two at option. | Ditto. |
| | ,, No. 3. | £85. | .... | Ditto. | Ditto. |
| | ,, No. 4. | £85. | .... | Competitive Examination among Students of Provincial University Colleges of similar standing in the same subjects. | Ditto. |
| | ,, No. 5. | £50. | .... | Competitive Examination among Students in the same subjects as Entrance Scholarship No. 1. | To enter St. George's School. |
| | ,, No. 6. | £50. | .... | Ditto. | Ditto. |
| | Wm. Brown Exhibition. | £100 per annum. | 2 years. | Competitive Examination among Perpetual Pupils having registrable qualification in the PRACTICE OF MEDICINE, MIDWIFERY, and SURGERY. | Study at St. George's School. |
| | ,, | £40 ,, ,, | 3 years. | Competition among Third-year Students in the same subjects. | Ditto. |
| | Brackenbury Prize in Medicine. | Interest on £1103. | .... | Competitive Examination among Students of not more than five years' standing. | None. |
| | Brackenbury Prize in Surgery. | Interest on £1103. | .... | Competitive Examination among Students of not more than five years' standing. | None. |
| | Treasurer's Prize. | £10 10s. | .... | Proficiency in Clinical Examination of three Medical and three Surgical Cases, together with a written Examination in Medicine, Surgery, and Midwifery. | None. |
| | H. C. Johnson Memorial Prize. | £10 10s. | .... | Competitive Examination in PRACTICAL ANATOMY. | None. |
| | Pollock Prize. | Interest on £372. | .... | Competitive Examination in PHYSIOLOGY, PHYSIOLOGICAL CHEMISTRY, and HISTOLOGY. | None. |
| | Clarke Prize. | Interest on £209. | .... | Awarded for Clinical Reports and Commentaries. | None. |
| | Thompson Medal. | Interest on £185. | .... | | |
| | Brodie Prize. | Interest on £220. | .... | | |
| | Acland Prize. | £5. | .... | | |

| BRISTOL ROYAL INFIRMARY AND BRISTOL GENERAL HOSPITAL—*Bristol Royal Infirmary—continued.* | Clark Prize. | £11 11s. | — | Class Work of Third-year Students. | Restricted to Perpetual Students who have done the necessary qualifying work at the Bristol Royal Infirmary. |
| | Crosby Leonard Prize. | £7 7s. | — | Examination in CLINICAL SURGERY. | |
| | Augustin Prichard Prize. | £7 7s. | — | Examination in SURGICAL ANATOMY. | |
| *Bristol General Hospital* ... | Sanders Scholarship. | £22 10s. | .... | Competitive Examination in MEDICINE, SURGERY, and MIDWIFERY of Fourth-year Students. | Restricted to Perpetual Students who have done the necessary qualifying work at the Bristol General Hospital. |
| | Clarke Scholarship. | £15. | .... | Competitive Examination in SURGERY among Students of Fourth Year. | |
| | Marshall Prize. | £9. | — | To the best Surgical Dresser of the year.. | |
| LEEDS SCHOOL OF MEDICINE (YORKSHIRE COLLEGE). | Entrance Scholarship. | £67 4s. | .... | Competitive Examination among Medical Students who have passed Preliminary Scientific Examination at London or Victoria University. | Complete Course of Lectures and Practical Classes at Leeds School. |
| | Infirmary Scholarship. | £42. | — | Competitive Examination in ARTS among Students who have passed one of the Preliminary Examinations. | Complete Course of Hospital Practice and Clinical Lectures at Leeds Infirmary. |
| | Hardwick Prize. | £10. | — | Competitive Examination among Clinical Clerk Students of two years' standing in CLINICAL MEDICINE. | |
| | McGill Prize. | £10. | — | Competitive Examination among advanced Surgical Students in CLINICAL SURGERY. | |
| | Thorp Prizes. | £10 and £5. | .... | Examinations in Forensic Medicine and Hygiene. | |
| | Thorp Prize Essay. | £15. | — | Essay or research on some subject connected with FORENSIC MEDICINE, TOXICOLOGY, or PUBLIC HEALTH. | Every three years to former student of the Leeds School. |
| | Scattergood Prize. | — | .... | Examination in MIDWIFERY. | |
| UNIVERSITY COLLEGE, LIVERPOOL. | Robert Gee Entrance Scholarships (four annually). | £25 each. | 1 year. | Special College Scholarship Examination held in May. | First M.B. Course. |
| | Holt Fellowships (Physiology and Pathology). | £100 each. | 1 year. | Vote of Faculty to Student after graduation. | Teaching and Original Research. |
| | Gee Fellowship (Anatomy). | £100. | 1 year. | Ditto. | Teaching and Research. |
| | Alexander Fellowship (Pathology). | £100. | 1 year. | Ditto. | Research in Pathology. |
| | Johnston Colonial Fellowship (Pathology and Bacteriology). | £100. | 1 year. | Ditto. | Ditto. |
| | Lyon Jones Scholarship. No. 1. | £21 per annum. | 2 years. | Competitive Examination among Junior Students in 1st M.B. SUBJECTS. | Perpetual Course at Victoria University. |
| | ,, No. 2. | £21. | — | Competitive Examination among Senior Students in ANATOMY, PHYSIOLOGY, and THERAPEUTICS. | |
| | Derby Exhibition. | £15. | — | Competitive Examination among Fourth- or Fifth-year Students in CLINICAL SUBJECTS. | |
| EDINBURGH UNIVERSITY | *Sibbald Bursaries (1 or 2 annually). | Each £30 per annum. | 3 years. | Competitive Examination in Preliminary Subjects among entrants. | Continued Study. |
| | *Heriot Bursaries (7 for men and 1 for women annually). | Each £30 per annum. | 3 years. | Ditto. | |
| | *Thomson Bursaries (2 annually). | Each £25 per annum. | 4 years. | Distinction in Medical Preliminary Examination. | Ditto. |
| | *Grierson Bursary. ,, No. 1. | £20. | 1 year. | Ditto. | Ditto. |
| | *Crichton Bursaries (2 or 3 annually). | Each £50 per annum. | 4 years. | Distinction in Medical Preliminary Examination, with extra subjects. | Born in Scotland. |
| | *Mackie Bursary. ,, No. 1. | £30 per annum. | 2 years. | — | Pecuniary circumstances requiring assistance, &c. |
| | *Junior J. A. Carlyle Bursary. | £28. | 1 year. | Distinction in Class Examinations in ANATOMY and CHEMISTRY. | |
| | *Coldstream Memorial Scholarship. | £25 per annum. | 5 years. | — | Intention to become Medical Missionary, &c. |

* For Students entering on or in their First Year.

"Ne quid nimis."

## THE CENTENARY OF THE OWENS COLLEGE.

THE Owens College was opened in 1851, so that its jubilee will coincide with the first year of the coming century. It was founded, as everyone knows, by Mr. John Owens, a Manchester merchant, but owes almost as much to the munificence of his friend Mr. George Faulkner, also a business man of Manchester. The former was a Liberal or Radical in politics and a Nonconformist, while the latter was a Churchman and a Tory, and this coöperation was happily a foretaste of the interest and help given to the College from its earliest days by men of very various political and religious views who were desirous for "university teaching and university work of the highest kind to form part of the city life." The time is fitting therefore for an authoritative account to be given of the College, independent of the fact that there was a demand for such information for the Educational Exhibition in London and for the Paris Exhibition. This want has been very satisfactorily supplied in a volume entitled, "A Brief History of the College and Description of its various Departments," edited by P. J. Hartog, B.Sc., and published by J. E. Cornish, Manchester. It is divided into 15 sections dealing with the history of the College, its government and administration, its relation to the Victoria University, its several departments of arts, science, law, and last, though not least, medicine. Like many other great institutions, the College in its early days passed through a period of non-appreciation and adversity, perhaps because Manchester as a community had not become alive to the importance and value of local university teaching and influence. The College opened with 62 students, but the number fell till in 1856–9 there were only 40, and it was said to be a "mortifying failure." Now there are over 1000, a number which has been nearly reached for ten years past. At first its endowment was rather less than £90,000, but now its capital account is very nearly ten times £90,000, and more than £650,000 of this sum have been added during the last 30 years. In 1872, when the College was reconstituted, the annual expenditure was under £10,000, it is now over £40,000. Several years ago the College took over the Manchester Museum which, though of interest and value, had fallen into a state of more or less dilapidation. This collection is rapidly becoming richer in its various departments, and in that of geology is acknowledged to be of special value to those practically interested in the mining resources of a wide district. But though interesting to many of the students of the College it is of far greater service to the general public and has a claim for more municipal support than it has so far received. Its proper income has to be supplemented by about £1400 a year drawn from the educational revenue of the College to maintain its efficiency. In 1894 a costly but absolutely needed extension of the medical department of the College was made and growth in one direction or another is constantly going on, and if the College is to continue equal to its ever-growing work must go on. This being so it necessarily follows that the munificence of the citizens is always welcomed and, indeed, craved for, and it is satisfactory to know that such munificence can scarcely be devoted to an object which will give a better return to the community. Owens College is, of course, the premier college of Victoria University, a group comprising colleges at Liverpool and Leeds also, but the seat of the University is by charter fixed at Manchester, where all University meetings must be held. Mr. Hartog's volume gives accounts, varying a good deal in fulness, of the various departments of study, those of the older subjects, as classics and mathematics, being more briefly treated than the more modern ones of engineering, education, physiology, and pathology. A sketch is also given of the original work emanating from the College during the last 30 years and the record is one of which no educational institution need be ashamed. Portraits are added of some of the benefactors of the College. "From its earliest days down to the present time the College has never wanted for enthusiastic and unselfish service," and invaluable help has been given by many who have avoided public recognition.

## SUPPOSED PLAGUE IN GLASGOW.

WE regret to state that several cases believed on good grounds to be plague have occurred in Glasgow. The first patient was a child living in Thistle-street, a thoroughfare on the south side of the river Clyde. The illness quickly proved fatal, and in the course of three or four days both of the parents and a third person living in the same house were attacked. All three were removed to the city hospital for infectious diseases at Belvidere on the supposition that they were suffering from enteric fever, but the medical officers of the hospital suspected the disease to be plague. Dr. Robert Muir, professor of pathology in the University, was asked to see the patients, one of whom died on August 28th. The latest information is to the effect that clinically and pathologically there seems to be no doubt of the disease being plague, but the inoculation experiments are not yet completed. The announcement is, no doubt, one to cause anxiety, but from the ability of modern sanitary science to localise outbreaks of infectious disease in well-governed communities there need be no occasion for panic.

## THE LATE SIR HENRY LUNNON SIMPSON.

THE veterinary profession has sustained a severe loss through the accidental death by drowning of Sir Henry Lunnon Simpson. Sir Henry Simpson was a native of Windsor and after obtaining the diploma of the Royal College of Veterinary Surgeons in 1861 joined his father in practice in that town. He was elected a Vice-President of his College in 1881 and was an active member of the Council between 1882 and 1890, during which time he was always energetically on the side of progress. In the Jubilee year of 1887 honours fell thick upon him, as, in addition to being unanimously elected President of the Council, he was made mayor of Windsor. It was in this year that he received from Her Majesty the honour of knighthood. Sir Henry Simpson had a large consultative and general practice, from the latter of which he was gradually retiring in favour of his son. He was well known in horse-judging and sporting circles, his particular hobbies being hunters and polo ponies. He was veterinary surgeon to the Royal buckhounds. The sad occurrence took place at his country residence, the South Lea estate, Datchet, on the morning of August 17th. He was very fond of walking by the Thames and, as was his usual custom after reading his letters, he went for a walk by the river bank. What happened exactly will never be known, but it is surmised that he had a fainting fit and fell in. He had for some time been the subject of cardiac trouble and had remarked upon his occasional attacks of giddiness. Sir Henry Simpson was an expert swimmer and in the place where the body was found the water was only about four feet deep. He was 58 years of age. The funeral took place at Windsor Cemetery on August 21st, representatives of all classes being present, for the deceased was an exceedingly popular man and much respected. Deep sympathy is felt with Lady Simpson and

family, the Queen and other members of the Royal family being amongst those who have sent messages of condolence.

COLONEL J. LANE NOTTER, R.A.M.C., has resigned the post of Professor of Military Hygiene in the Army Medical School, Netley, and has, as we have already announced, left for South Africa as a member of the Commission of Inquiry into the causes of the great prevalence in many South African districts of enteric fever. He will also act as adviser to the Commander in-Chief as to the selection of sites for barracks and standing camps. We understand that the Professorship of Military Hygiene has been offered to Major R. Hammill Firth, F.R.C.S. Eng., R.A.M.C., formerly Assistant Professor.

DR. R. BLONDEL, who acted as the General Secretary of the First International Congress of the Medical Press recently held in Paris, has been named a Chevalier of the Legion of Honour.

## THE PRESENT POSITION OF PATHOLOGY IN ENGLAND.

*To the Editors of* THE LANCET.

SIRS,—It is somewhat remarkable, considering the advances in medicine and surgery due to pathological investigation, that the science of pathology should be held in such low esteem by the majority of the medical profession. Pathologists are consultants as much as surgeons and physicians and as such they ought to receive adequate fees, yet we find that while the opinion of a physician or surgeon is supposed to be worth two guineas or more the opinion of a pathologist is usually valued at about 5*s*. This is owing to the numerous "research associations" which have sprung up of late years in different parts of the country. These associations, as a rule, impose no limit whatever as regards the examination of material sent to them, they are backed up by the leading members of the profession and in some instances by the professors of pathology at the medical schools.

We have heard a great deal lately about the abuse of hospitals and clubs, but surely it is just as great an abuse that—to take an example—a surgeon who receives a large fee for the removal of a tumour can obtain a pathological report as to its nature for the sum of 5*s*. In a large number of these cases this report is of vital importance as regards diagnosis, prognosis, and treatment, and upon it may turn the result of medico-legal cases, yet it is supposed to be only worth a fee which a consulting physician or surgeon would refuse to take. Again, the low esteem in which pathology is held is shown by the way in which the pathological department at our larger hospitals is conducted. In a great number of these hospitals there is either no pathologist at all or if there is one he is in a very subordinate position and has no direct voice in the management of his department. This is strikingly seen on looking through the lists of officers of the large hospitals. Very few of these appoint pathologists on their staff and these are usually assistant physicians at the same time who, however capable they may be, may not have the necessary amount of time to devote to pathological work. Post-mortem examinations and microscopical investigations are often carried out by a house physician who has probably had no special training in pathology and who is hardly in a position to demonstrate the morbid changes to the students and others who may be present. As a matter of fact, physicians and surgeons look upon pathological investigation as a mere mechanical process of cutting sections, &c., and forget that to be able to interpret the appearances in the prepared specimens requires years of special study and experience.

Let us now see how this state of things can be remedied. All research associations and similar bodies should strictly confine their work to those cases in which an adequate fee cannot be obtained. The managers of these bodies should confer together and come to a definite understanding on this point. In the case of hospitals in connexion with medical schools the lecturer on pathology should be pathologist to the hospital. He should rank with the visiting staff and should have a direct voice in the management of his department. He should conduct post-mortem examinations and should be responsible for the pathological reports. He should have an assistant, preferably a resident, who should have the same relation to him as a house physician has to the visiting physician. The assistant would do the routine pathological and bacteriological work of the hospital, and would submit the results to the pathologist who would sign the reports. In the absence of the pathologist the assistant would himself conduct post-mortem examinations and would sign the reports. Post-mortem examinations should be systematically carried out at a fixed time, and as far as possible should not clash with other hospital duties. The post-mortem demonstration forms a most important part of the pathological course, and it should be in the same hands as the lectures and practical work. If it is impossible to have a special assistant for the hospital work, the duties might be carried out by one of the demonstrators of pathology. The pathological laboratories of the medical school should be devoted to teaching and research and should not be overburdened with work for sanitary authorities who should appoint their own bacteriologist and should have their own laboratories. Lastly all pathological reports in published cases should be attested by the name of the pathologist responsible for the report. This is an important point which is too often neglected.

If these reforms were carried out it would do much to raise the status of pathology, and, in consequence, there would be a considerable increase in the numbers of those who would take up pathology as a special line of study.

I am, Sirs, yours faithfully,
CHARLES POWELL WHITE, M.D. CANTAB.,
F.R.C.S. ENG.

## MEDICAL TEACHERS.

MR. R. C. B. KERIN, B.A., London, first in First Class Honours in Classics, assisted by a staff of B.A. and B.Sc. Honour Graduates, prepares candidates in class and by private tuition for Medical Preliminaries, London Matriculation, Preliminary Scientific Inter. Science, Hospital Scholarships, First Conjoint, First M.B. Lond., Oxon., and Camb., &c. Biological, Chemical, and Physical Laboratories. For last six years 150 London University Successes and three Hospital Science Scholarships, &c.—Carlyon College, 55 and 56, Chancery-lane, W.C.

THE UNIVERSITY EXAMINATION POSTAL INSTITUTION prepares candidates either through the post or orally for all Medical Examinations, especially the M.D. (London or Durham), the D.P.H. (Cambridge or London), and the F.R.C.S. (England or Edinburgh). There are five tutors holding the M.D. or M.S. degree for the postal preparation, besides other tutors for laboratory work. The institution has a well-equipped laboratory for Public Health work, including Bacteriology. The Manager is Mr. E. S. Weymouth, M.A., 27, Southampton-street, Strand, London, W.C.

M.D., B.S. LOND. prepares for all the Professional Exams. Small classes are held for the Final College of Surgeons and Physicians, the Hall, the M.D.'s of Brussels and Durham (15 years' standing). Tuition by correspondence.—Address, M.D., 23, Wimpole-street, Cavendish-square, W.

Special preparations, in class, privately, and by correspondence, for the Triple Qualification, Edinburgh. Also for Fellowship Examinations of Royal College of Surgeons, Edinburgh, and M.D. Brussels. Resident pupils received.—Address, CLASS ROOMS, 7, Chambers-street, Edinburgh.

Coaching for Examination (University of Brussels). Also Correspondence Course for Provincial Practitioners, with practical and *viva voce* work in London before going to Brussels.—Address, CANTAB., 38, Manchester-street, Manchester-square, W.

Classes for the Navy Medical Service are held at 46, Great Ormond-street, W.C. Those for the November Competitions begin on Monday, Sept. 18th, at 11 A.M.—E. C. DUCHESNE, Secy.

INSTRUCTORS IN ELOCUTION, &c.

Professor ALTSCHUL, Ph.D., has made Stammering, Stuttering, Lisping, Falsetto, recent or of long standing, due to nervousness, &c., irrespectively of age or sex (without any mechanical appliance), his special life-long study. The voice greatly developed and strengthened.—9, Old Bond-street, W. (Attends at Brighton.)

Mr. WILLIAM VAN PRAAGH, the public introducer of the Pure Oral System of teaching Deaf Mutes, has made the subject of Lip-reading and the cure of all Defects of Speech, both acquired and congenital, his special study. Papers on the various subjects can be had at 11, Fitzroy-square, W.

Mrs. EMIL BEHNKE gives instruction in Voice Training and treats Stammering and other Defects of Speech at 18, Earl's-court-square, S.W.

# Births, Marriages, and Deaths.

## DEATHS.

BROWN.—On August 27th, at Walton-on-Thames, Robert Gosset Brown, Esq., M.D., M.R.C.P. Lond., after nearly two years of much suffering borne with patient resignation. R.I.P.

WALLIS.—On August 19th, at The Cedars, Aldershot, William Edward James Wallis, M.B. Edin., aged 25 years.

WEBSTER.—On August 18th, at Middlesbrough, Arthur Webster, M.R.C.S. Eng., L.R.C.P. Lond., aged 32 years.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

### *OUR CURRENT NUMBER*

*Being almost exclusively devoted to information especially interesting to Students we are necessarily compelled to defer the publication of communications on other important subjects.*

*We tender our best thanks to those gentlemen who have at considerable personal trouble kindly supplied us with the returns and prospectuses upon which the information given in this Students' Number of* THE LANCET *relative to the various medical examining bodies, hospitals, and medical schools of the United Kingdom is based. We regret that in some cases, however, owing to proofs having been either not returned at all or too late, certain inaccuracies may be found.*

---

*TO ADVERTISERS.*

*Owing to the pressure on our advertisement columns this week some announcements have unavoidably been held over.*

## Communications, Letters, &c., have been received from—

A.—Mr. B. G. Advani, Portland; Messrs. Armour and Co., Lond.; Mr. T. H. Agnew, Liverpool; Messrs. Allen and Hanburys, Lond.; A. W.; Army Medical Department, Director-General of; Rev. J. W. Atkinson, Lond.; Mr. P. Allen, Lond.

B.—Mr. A. Benthall, Catford; Mr. C. Birchall, Liverpool; Mr. H. E. Burch, Buluwayo; Mr. G. D. Barton, Lond.

C.—Dr. F. H. A. Clayton, R.N.; Dr. H. Campbell, Lond.; Dr. J. H. Cook, Calcutta; County Asylum, Lancaster, Clerk to; Corporation of Newcastle-on-Tyne, Medical Superintendent of; Dr. L. Cerf, Angers; Messrs. J. A. Carveth and Co., Toronto; Cortland Wagon Co., Lond.; Messrs. Cassell and Co., Lond.; Messrs. T. Christy and Co., Lond.; Messrs. C. J. Clay and Sons, Lond.; Dr. A. Cox, Gateshead; Dr. A. J. Chalmers, Liverpool.

D.—Lieutenant-Colonel G. W. P. Dennys, I.M.S., Sidmouth; Messrs. Debenham, Tewson, and Co., Lond.; Mr. R. Davis, Lond.; Mrs. Dodgson, Lond.; Dubious, Hinderwell; Messrs. Davies, Lond.; Mr. G. Drury, Newcastle-on-Tyne.

E.—Mr. C. Etheridge, Whitstable; Captain H. M. Earle, I.M.S., Ferozepore, India; Early Closing Association, Assistant Secretary of; Dr. A. G. Edington, Grahamstown; Enquirer, Eckington; Mr. T. S. Ellis, Gloucester.

F.—Dr. W. H. Forsbrook, Lond.; Mr. F. H. Foulds, Droitwich; Mr. W. T. Freeman, Reading; F. C. W.; Mr. E. H. Freeland, Lond.; Mr. M. Finucane, Aldershot.

G.—Mr. R. J. Gillanders, Fortrose; Messrs. Gardner and Co., Wisbech; Dr. Guido Guerrini, Bologna; Mr. P. G. Garrett, Pendleton.

H.—Mr. C. J. Harris, Lond.; Dr. J. A. Hutton, Scarborough; Dr. J. H. Hunter, South Shields; Dr. J. S. Hicks, Falmouth; Borough of Hastings, Town Clerk of.

I.—Mr. R. Inwards, Lond.

J.—Messrs. W. & A. K. Johnston, Edinburgh; J. H. G.; Mr. P. Napier Jones, Plaistow; Dr. Mary D. Jones, New York.; J. W. H.

K.—Dr. H. Kenwood, Lond.

L.—Mr. J. C. Lindop, Lond.; Lynn Rural District, Medical Officer of Health of; London Throat Hospital, Hon. Secretary of; Mr. H. K. Lewis, Lond.; Mr. C. C. Vacy Lyle, Guernsey; London College of Pharmacy, &c., Principal of.

M.—Dr. A. S. Morton, Putney; Medical Society of Victoria, Melbourne, Hon. Treasurer of, Manchester Medical Agency; Mr. H. Marsh, Lond.; Mr. H. H. Mason, Lond.; *Midland Counties Herald*, Birmingham; Medical Graduates' College and Polyclinic; Dr. J. D. P. McLatchie, Lond.; Dr. E. J. McWeeney, Dublin.

N.—Mr. F. A. Nodal, Manchester; Mr. H. Needes, Lond.; North Shields Dispensary, Hon. Secretary of; Mr. B. L. Nicholson, Chester-le-Street.

O.—Mr. G. Olliver, Brighton; Mr. C. A. P. Osburne, Old Catton; Dr. J. B. Oliver, Liverpool; Mr. G. W. Ord, Richmond; Dr. F. Orton, Lond.

P.—Mr. Y. J. Pentland, Edinburgh; Mr. W. Poppelreuter, Manchester; Messrs. Parke, Davis, and Co., Lond.; P. P.; Practitioner, Brandon; Dr. C. Y. Pearson, Cork; Dr. S. W. Plummer, Durham; Mr. J. Plummer, Sydney; Dr. O. Paget, Freemantle; Mr. J. B. Pike, Loughborough.

R.—Dr. E. Rayner, Stockport; Messrs. Reynolds and Branson, Leeds; Royal Isle of Wight Infirmary, Ryde, Secretary of; Dr. D. R. Rowlands, Edgbaston; Mr. R. H. Russell, Farningham; Dr. Nathan Raw, Liverpool; Mr. T. B. Read, Oldham.

S.—Mr. E. Sturridge, Lond.; Mr. Noble Smith, Lond.; Scholastic, Clerical, &c., Association, Lond.; Dr. R. Sturgis-White, Cradley; Messrs. Street and Co., Lond.; Mr. K. Scott, Lond.; St. Mungo's College, Glasgow, Secretary of; Mr. J. W. Staniforth, Hinderwell; Dr. T. C. Squance, Sunderland; Mr. J. L. Stretton, Kidderminster.

T.—Tallerman Institute, Lond.; Messrs. C. Tayler and Co., Lond.; Tottenham Hospital, Secretary of; Dr. R. Thomson, Margate; *Torquay Times*.

U.—University College, Lond.; University Examination Postal Institution, Manager of.

V.—Mr. F. A. Verney, Ixopo, Natal.

W.—Mr. D. J. Williams, Cardiff; *Wisconsin Medical Recorder*, Editor of; Dr. M. Waldheim, Millstatt, Austria; Messrs. J. Wright and Co., Bristol; Mr. T. B. Whitelaw, Tyldesley; Major J. H. T. Walsh, I.M.S.; Mr. S. Wand, Leicester.

## Letters, each with enclosure, are also acknowledged from—

A.—A. R. A.

B.—Mr. W. Brown, Backworth; Dr. E. R. Bowen, Barry Deck; Dr. H. C. Bhuttacharjee, Cawnpur, India; Bristol Royal Hospital for Sick Children, Secretary of; B. R.; Dr. R. W. Baxter, Bromley.

C.—Mr. J. E. Cornish, Manchester; Dr. A. Crawford, Lond.; Cantab, Lond.; Church Agency, Lond.; Mr. W. H. Cook, Huddersfield; Messrs. A. Cohen and Co., Lond.; County Asylum, Prestwich, Treasurer of; Lieutenant-Colonel T. Clarke, Sialkote, India; Messrs. J. W. Cooke and Co., Lond.; Messrs. Cowie and Co., Lond.; Mrs. E. M. Champness, Rochdale.

D.—Mr. J. W. Disney, Kingstown; Dover Hospital, Hon. Secretary of.

E.—Mr. J. Edwards, Liverpool; Mr. H. T. Evans, Blackwood; Messrs. Elliott, Son, and Boyton, Lond.; Mr. F. G. Ernst, Lond.

F.—Messrs. Fassett and Johnson, Lond.; F. G.

G.—Mr. B. B. Gough, Capel; Gwilym, Walkley; G. A. B.; Mr. H. Greenwood, St. Just; Messrs. Gilyard Bros., Bradford; G. E. B.; G. W.

H.—Mr. A. Hawkyard, Hunslet; Miss K. Hogg, Lond.; H. C. W.; Messrs. J. Haddon and Co., Lond.; H. R.; Mr. G. Hume, Newcastle-on-Tyne.

I.—Messrs. Ingram and Royle, Lond.

J.—Mr. E. O. Jones, Merthyr Tydfil; Dr. R. O. Joyce, Porth, Dr. C. H. L. Johnston, St. John, N.B.; Mr. J. P. Jones, Corris; Mr. D. J. Jones, Blaenavon; J. R. S.; J. H. J.; J. S. W.; J. F.

K.—Mr. R. C. B. Kerin, Lond.; Mr. V. R. Kirlosker, Jamkhandi, India; Mr. W. Kirkby, Maesteg.

L.—Mr. R. J. Lyle, Omagh; Mr. J. L. Leckie, Pontypridd; Messrs. T. Lewin and Co., Lond.; Leeds Trained Nurses' Institute, Superintendent of; London Temperance Hospital, Secretary of; L. B.

M.—Mr. A. Moxon, Nuneaton; Messrs. Moore and Co., Lond.; Mr. J. A. H. Mogg, Feckenham; Messrs. E. MacGeorge and Co., Lond.; Medicus, Aston; Dr. Mason, Lond.; M. K. S.; Messrs. Millikin and Lawley, Lond.; Messrs. W. Mate and Sons, Boscombe; Dr. D. A. MacGregor, Clayton West; Manchester Royal Eye Hospital, Secretary of; Medical Supply Association, Dublin; M. G. M. E.

N.—Northern Medical Association, Glasgow; Nottingham City Asylum, Clerk of; National Hospital for the Paralysed, Lond., Secretary of.

P.—Mr. E. A. B. Poole, Stonebroom; Mr. F. W. Provost, Harrow-on-the-Hill; Poplar Union, Clerk of; Proprietor, Swanage; Mr. C. J. Perrott, Bristol; Physician, Lond.; Mr. J. E. Proud, Middlesbrough.

R.—Mr. A. Ramsay, Acton; R. M.; Mr. R. Richardson, Handsworth; Royal Devon and Exeter Hospital, Secretary of; Royal United Hospital, Bath, Secretary of.

S.—Mr. J. Stott, Haslingden; Dr. Stevenson, Darlington; Lady P. Stewart, Arundel; Mr. W. Smith, Aberdeen; South Australian Government Bonded Depôt, Lond., Manager of; Mrs. S.; Messrs. Squire and Sons, Lond.; Surgeon, Taunton; Dr. W. H. Smith, Meriden; Sigma, Leeds; Salford Royal Hospital, Secretary of.

T.—Mr. W. E. Tarbet, Ledbury; T. W. B.

W.—Mr. W. Wallace, Leicester; Dr. J. S. Wallace, Kingston-on-Thames; Mr. R. Walker, Aberdeen; W. E. R.; Mrs. Warden, St. Leonards-on-Sea; Mr. E. Welchman, Heckington; Messrs. Wright, Layman, and Umney, Lond.; Mr. C. H. Whiteford, Plymouth; W. E. S.; W. A. W.; W. R. E., Wrexham Infirmary, House Surgeon of.

EVERY FRIDAY.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 3, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

**Agent for the Advertisement Department in France.—J. ASTIER, 8, Rue Traversière, Asnières, Paris.**

# Presidential Address

ON

# SOME ASPECTS OF BIOLOGY.

*Delivered at the Meeting at Bradford, on Sept. 5th, 1900, of the British Association for the Advancement of Science,*

BY SIR WILLIAM TURNER, M.B. LOND., D.C.L. OXON., LL.D. GLASG. & MONTREAL, D.SC. CAMB. & DUB, F.R.S.,

PRESIDENT OF THE ASSOCIATION, PRESIDENT OF THE GENERAL MEDICAL COUNCIL, AND PROFESSOR OF ANATOMY IN THE UNIVERSITY OF EDINBURGH.

SIR WILLIAM TURNER commenced by recalling the former meeting of the Association held in Bradford 27 years ago. He then referred to the deaths of two past presidents which had occurred since the Dover meeting—namely, those of the Duke of Argyll, president at Glasgow in 1855, and Sir J. W. Dawson, president at Birmingham in 1886. He then proceeded to lay down the qualities necessary for scientific method. In scientific research, he said, diligence and accuracy are fundamental qualities. ..... Scientific method consists, therefore, in close observation, frequently repeated so as to eliminate the possibility of erroneous seeing; in experiments checked and controlled in every direction in which fallacies might arise; in continuous reflection on the appearances and phenomena observed, and in logically reasoning out their meaning and the conclusions to be drawn from them. Were the method followed out in its integrity by all who are engaged in scientific investigations the time and labour expended in correcting errors committed by ourselves or by other observers and experimentalists would be saved and the volumes devoted annually to scientific literature would be materially diminished in size. Were it applied, as far as the conditions of life admit, to the conduct and management of human affairs we should not require to be told when critical periods in our welfare as a nation arise that we shall muddle through somehow. Recent experience has taught us that wise discretion and careful prevision are as necessary in the direction of public affairs as in the pursuit of science, and in both instances when properly exercised they enable us to reach with comparative certainty the goal which we strive to attain.

Sir William Turner then reminded his audience of the improvements in methods of observation which modern times had brought forth. A certain amount of gross anatomy had been known from very early times, but even down to the early part of this century but little more was known of the texture of the animal body than could be determined by the naked eye, assisted by a simple lens. Thus nerves, muscles, and tendons were known to be composed of fibres and blood- and lymph-vessels were known to be tubes. In 1830 Joseph Jackson Lister read a paper before the Royal Society upon the principles of the construction of achromatic object glasses for microscopes. One outcome of the increased penetrative powers of the microscope was Schwann's great cell theory announced in 1839. The enunciation of the fundamental principle that the elementary tissues consisted of cells constituted a step in the progress of biological science which will for ever stamp the century now drawing to a close with a character and renown equalling those which it has derived from the most brilliant discoveries in the physical sciences.

## STRUCTURE OF CELLS.

Sir William Turner continued: A cell is a living particle, so minute that it needs a microscope for its examination; it grows in size, maintains itself in a state of activity, responds to the action of stimuli, reproduces its kind, and in the course of time it degenerates and dies. Let us glance at the structure of a cell to determine its constituent parts and the rôle which each plays in the function to be discharged. The original conception of a cell, based upon the study of the vegetable tissues, was a minute vesicle enclosed by a definite wall, which exercised chemical or metabolic change on the surrounding material and secreted into the vesicle its characteristic contents. A similar conception was at first also entertained regarding the cells of animal tissues; but as observations multiplied it was seen that numerous elementary particles, which were obviously in their nature cells, did not possess an enclosing envelope. A wall ceased to have a primary value as a constituent part of a cell, the necessary vesicular character of which, therefore, could no longer be maintained. The other constituent parts of a cell are the cell plasm, which forms the body of the cell, and the nucleus embedded in its substance. Notwithstanding the very minute size of the nucleus, which even in the largest cells is not more than $\frac{1}{500}$th inch in diameter, and usually is considerably smaller, its almost constant form, its well-defined sharp outline, and its power of resisting the action of strong reagents when applied to the cell, have from the period of its discovery by Robert Brown caused histologists to bestow on it much attention. Its structure and chemical composition; its mode of origin; the part which it plays in the formation of new cells, and its function in nutrition and secretion have been investigated. When examined under favourable conditions in its passive or resting state, the nucleus is seen to be bounded by a membrane which separates it from the cell plasm and gives it the characteristic sharp contour. It contains an apparently structureless nuclear substance, nucleoplasm or enchylema, in which are embedded one or more extremely minute particles called nucleoli, along with a network of exceedingly fine threads or fibres, which in the active living cell play an essential part in the production of new nuclei within the cell. In its chemical composition the nuclear substance consists of albuminous plastin and globulin and of a special material named nuclein, rich in phosphorus and with an acid reaction. The delicate network within the nucleus consists apparently of the nuclein, a substance which stains with carmine and other dyes, a property which enables the changes which take place in the network in the production of young cells to be more readily seen and followed out by the observer. The mode of origin of the nucleus and the part which it plays in the production of new cells have been the subject of much discussion. Schleiden, whose observations, published in 1838, were made on the cells of plants, believed that within the cell a nucleolus first appeared, and that around it molecules aggregated to form the nucleus. Schwann, again, whose observations were mostly made on the cells of animals, considered that an amorphous material existed in organised bodies, which he called "cytoblastema." It formed the contents of cells, or it might be situated free or external to them. He figuratively compared it to a mother liquor in which crystals are formed. Either in the cytoblastema within the cells or in that situated external to them, the aggregation of molecules around a nucleolus to form a nucleus might occur, and when once the nucleus had been formed in its turn it would serve as a centre of aggregation of additional molecules from which a new cell would be produced. He regarded, therefore, the formation of nuclei and cells as possible in two ways: one within pre-existing cells (endogenous cell-formation), the other in a free blastema lying external to cells (free cell-formation). In animals, he says, the endogenous method is rare and the customary origin is in an external blastema. Both Schleiden and Schwann considered that after the cell was formed the nucleus had no permanent influence on the life of the cell and usually disappeared. Under the teaching principally of Henle, the famous professor of anatomy in Göttingen, the conception of the free formation of nuclei and cells in a more or less fluid blastema by an aggregation of elementary granules and molecules obtained so much credence, especially amongst those who were engaged in the study of pathological processes, that the origin of cells within pre-existing cells was to a large extent lost sight of. That a parent cell was requisite for the production of new cells seemed to many investigators to be no longer needed. Without doubt this conception of free cell-formation contributed in no small degree to the belief, entertained by various observers, that the simplest plants and animals might arise, without pre-existing parents, in organic fluids destitute of life, by a process of spontaneous generation—a belief which prevailed in many minds almost to the present day. If, as has been stated, the doctrine of abiogenesis cannot be experimentally refuted, on the other hand it has not been experimentally proved. The burden of proof lies with those

who hold the doctrine, and the evidence that we possess is all the other way.

Apparently the first to recognise a multiplication of cells in plants by division, was von Mohl in 1835. Von Baer and others had recognised the germinal vesicle in the animal ovum before 1839 and Barry in 1839 and 1840 communicated two papers to the Royal Society describing the multiplication of cells in or of the ovum.

John Goodsir and his brother Harry in 1842 and 1845 described the cleavage of cell nuclei and Remak (1850–1855) confirmed the idea that the nucleus was the starting point for multiplication of cells. Finally Virchow in 1858 in his Cellular Pathology gave the death-blow to the theory of the free formation of cells in blastema and laid down his well-known formula, *Omnis cellula e cellulâ*.

### KARYOKINESIS.

The nucleus in its passive or resting stage contains a very delicate network of threads or fibres. The first stage in the process of nuclear division consists in the threads arranging themselves in loops and forming a compact coil within the nucleus. The coil then becomes looser, the loops of threads shorten and thicken, and somewhat later each looped thread splits longitudinally into two portions. As the threads stain when colouring agents are applied to them, they are called chromatin fibres, and the loose coil is the chromosome (Waldeyer). As the process continues the investing membrane of the nucleus disappears and the loops of threads arrange themselves within the nucleus so that the closed ends of the loops are directed to a common centre, from which the loops radiate outwards and produce a star-like figure (aster). At the same time clusters of extremely delicate lines appear both in the nucleoplasm and in the body of the cell, named the achromatic figure, which has a spindle-like form with two opposite poles and stains much more feebly than the chromatic fibres. The loops of the chromatic star then arrange themselves in the equatorial plane of the spindle and bending round turn their closed ends towards the periphery of the nucleus and the cell. The next stage marks an important step in the process of division of the nucleus. The two longitudinal portions into which each looped thread had previously split now separate from each other, and whilst one part migrates to one pole of the spindle the other moves to the opposite pole and the free ends of each loop are directed towards its equator (metakinesis). By this division of the chromatin fibres and their separation from each other to opposite poles of the spindle two star-like chromatin figures are produced (dyaster). Each group of fibres thickens, shortens, becomes surrounded by a membrane, and forms a new or daughter nucleus (dispirem). Two nuclei, therefore, have arisen within the cell by the division of that which had previously existed, and the expression formulated by Flemming—*omnis nucleus e nucleo*—is justified. Whilst this stage is in course of being completed the body of the cell becomes constricted in the equatorial plane of the spindle, and as the constriction deepens it separates into two parts, each containing a daughter nucleus, so that two nucleated cells have arisen out of a pre-existing cell. A repetition of the process in each of these cells leads to the formation of other cells, and although modifications in details are found in different species of plants and animals the multiplication of cells in the egg and in the tissues generally on similar lines is now a thoroughly established fact in biological science.

In the study of karyokinesis importance has been attached to the number of chromosomes in the nucleus of the cell. Flemming had seen in the salamander 24 chromosome fibres, which seems to be a constant number in the cells of epithelium and connective tissues. In other cells, again, especially in the ova of certain animals, the number is smaller, and 14, 12, four, and even two only have been described. The theory formulated by Boveri that the number of chromosomes is constant for each species, and that in the karyokinetic figures corresponding numbers are found in homologous cells, seems to be not improbable. In the preceding description I have incidentally referred to the appearance in the proliferating cell of an achromatic spindle-like figure. Although this was recognised by Fol in 1873 it is only during the last 10 or 12 years that attention has been paid to its more minute arrangements and possible signification in cell-division. The pole at each end of the spindle lies in the cell plasm which surrounds the nucleus. In the centre of each pole is a somewhat opaque spot (central body) surrounded by a clear space, which, along with the spot, constitutes the centrosome or the sphere of attraction. From each centrosome extremely delicate lines may be seen to radiate in two directions. One set extends towards the pole at the opposite end of the spindle and, meeting or coming into close proximity with radiations from it, constitutes the body of the spindle, which, like a perforated mantle, forms an imperfect envelope around the nucleus during the process of division. The other set of radiations is called the polar and extends in the region of the pole towards the periphery of the cell. The question has been much discussed whether any constituent part of the achromatic figure, or the entire figure, exists in the cell as a permanent structure in its resting phase, or if it is only present during the process of karyokinesis. During the development of the egg the formation of young cells, by division of the segmentation nucleus, is so rapid and continuous that the achromatic figure, with the centrosome in the pole of the spindle, is a readily recognisable object in each cell. The polar and spindle-like radiations are in evidence during karyokinesis and have apparently a temporary endurance and function. On the other hand, van Beneden and Boveri were of opinion that the central body of the centrosome did not disappear when the division of the nucleus came to an end, but that it remained as a constituent part of a cell lying in the cell plasm near to the nucleus. Flemming has seen the central body with its sphere in leucocytes, as well as in epithelial cells and those of other tissues. Subsequently Heidenhain and other histologists have recorded similar observations. It would seem, therefore, as if there were reason to regard the centrosome, like the nucleus, as a permanent constituent of a cell. This view, however, is not universally entertained. If not always capable of demonstration in the resting stage of a cell it is doubtless to be regarded as potentially present and ready to assume, along with the radiations, a characteristic appearance when the process of nuclear division is about to begin. One can scarcely regard the presence of so remarkable an appearance as the achromatic figure without associating with it an important function in the economy of the cell. As from the centrosome at the pole of the spindle both sets of radiations diverge, it is not unlikely that it acts as a centre or sphere of energy and attraction. By some observers the radiations are regarded as substantive fibrillar structures, elastic or even contractile in their properties. Others, again, look upon them as morphological expressions of chemical and dynamical energy in the protoplasm of the cell body. On either theory we may assume that they indicate an influence, emanating, it may be, from the centrosome and capable of being exercised both on the cell plasm and on the nucleus contained in it. On the contractile theory the radiations which form the body of the spindle, either by actual traction of the supposed fibrillæ or by their pressure on the nucleus which they surround, might impel during karyokinesis the dividing chromosome elements towards the poles of the spindle to form there the daughter nuclei. On the dynamical theory the chemical and physical energy in the centrosome might influence the cell plasm and the nucleus and attract the chromosome elements of the nucleus to the poles of the spindle. The radiated appearance would therefore be consequent and attendant on the physico-chemical activity of the centrosome. One or other of these theories may also be applied to the interpretation of the significance of the polar radiations.

### CELL PLASM.

In the cells of plants, in addition to the cell wall, the cell body and the cell juice require to be examined. The material of the cell body, or the cell contents, was named by von Mohl (1846) "protoplasm," and consisted of a colourless tenacious substance which partly lined the cell wall (primordial utricle), and partly traversed the interior of the cell as delicate threads enclosing spaces (vacuoles) in which the cell juice was contained. In the protoplasm the nucleus was embedded. Nägeli, about the same time, had also recognised the difference between the protoplasm and the other contents of vegetable cells, and had noticed its nitrogenous composition. Though the analogy with a closed bladder or vesicle could no longer be sustained in the animal tissues the name "cell" continued to be retained for descriptive purposes and the body of the cell was spoken of as a more or less soft substance enclosing a nucleus (Leydig). In 1861 Max Schultze adopted for the substance forming the body of the animal cell the term "protoplasm." He defined a cell to be a particle of protoplasm in the substance of

which a nucleus was situated. He regarded the protoplasm, as indeed had previously been pointed out by the botanist Unger, as essentially the same as the contractile sarcode which constitutes the body and pseudopodia of the amœba and other rhizopoda. As the term "protoplasm," as well as that of "bioplasm" employed by Lionel Beale in a somewhat similar though not precisely identical sense, involves certain theoretical views of the origin and function of the body of the cell it would be better to apply to it the more purely descriptive term "cytoplasm" or "cell plasm." Schultze defined protoplasm as a homogeneous, glassy, tenacious material, of a jelly-like or somewhat firmer consistency, in which numerous minute granules were embedded. He regarded it as the part of the cell especially endowed with vital energy, whilst the exact function of the nucleus could not be defined. Based upon this conception of the jelly-like character of protoplasm the idea for a time prevailed that a structureless, dimly granular jelly or slime destitute of organisation possessed great physiological activity and was the medium through which the phenomena of life were displayed.

More accurate conceptions of the nature of the cell plasm soon began to be entertained. Brücke recognised that the body of the cell was not simple but had a complex organisation. Flemming observed that the cell plasm contained extremely delicate threads which frequently formed a network the interspaces of which were occupied by a more homogeneous substance. Where the threads crossed each other granular particles (mikrosomen) were situated. Bütschli considered that he could recognise in the cell plasm a honeycomb like appearance as if it consisted of excessively minute chambers in which a homogeneous more or less fluid material was contained. The polar and spindle-like radiations visible during the process of karyokinesis, which have already been referred to, and the presence of the centrosome, possibly even during the resting stage of the cell, furnished additional illustrations of differentiation within the cell plasm. In many cells there appears also to be a difference in the character of the cell plasm which immediately surrounds the nucleus and that which lies at and near the periphery of the cell. The peripheral part (ektoplasma) is more compact and gives a definite outline to the cell, although not necessarily differentiating into a cell membrane. The inner part (endoplasma) is softer, and is distinguished by a more distinct granular appearance, and by containing the products specially formed in each particular kind of cell during the nutritive process. By the researches of numerous investigators on the internal organisation of cells in plants and animals a large body of evidence has now been accumulated which shows that both the nucleus and the cell plasm consist of something more than a homogeneous, more or less viscid, slimy material. Recognisable objects in the form of granules, threads, or fibres can be distinguished in each. The cell plasm and the nucleus respectively are therefore not of the same constitution throughout but possess polymorphic characters the study of which in health and the changes produced by disease will for many years to come form important matters for investigation.

### FUNCTION OF CELLS.

Sir William Turner then shortly sketched the various functions of cells and gave a brief retrospect of the researches of Schwann, Henle, the Goodsirs, and others who had studied and are studying the subject. He continued—

### NERVE CELLS.

Of recent years great attention has been paid to the intimate structure of nerve cells and to the appearance which they present when in the exercise of their functional activity. A nerve cell is not a secreting cell, that is, it does not derive from the blood or surrounding fluid a pabulum which it elaborates into a visible, palpable secretion characteristic of the organ of which the cell is a constituent element, to be in due course discharged into a duct which conveys the secretion out of the gland. Nerve cells, through the metabolic changes which take place in them in connexion with their nutrition are associated with the production of the form of energy specially exhibited by animals which possess a nervous system, termed nerve energy. It has long been known that every nerve cell has a body in which a relatively large nucleus is situated. A most important discovery was the recognition that the body of every nerve cell had one or more processes growing out from it. More recently it has been proved, chiefly through the researches of Schultze, His, Golgi, and Ramon y Cajal, that at least one of the processes, the axon of the nerve cell, is continued into the axial cylinder of a nerve fibre and that in the multipolar nerve cell the other processes, or dendrites, branch and ramify for some distance away from the body. A nerve fibre is therefore an essential part of the cell with which it is continuous, and the cell, its processes, the nerve fibre, and the collaterals which arise from the nerve fibre collectively form a neuron or structural nerve unit (Waldeyer). The nucleated body of the nerve cell is the physiological centre of the unit. The cell plasm occupies both the body of the nerve cell and its processes. The intimate structure of the plasm has, by improved methods of observation introduced during the last eight years by Nissl and conducted on similar lines by other investigators, become more definitely understood. It has been ascertained that it possesses two distinct characters which imply different structures. One of these stains deeply on the addition of certain dyes, and is named "chromophile" or "chromatic substance"; the other, which does not possess a similar property, is the "achromatic network." The chromophile is found in the cell body and the dendritic processes but not in the axon. It occurs in the form of granular particles, which may be scattered throughout the plasm or aggregated into little heaps which are elongated or fusiform in shape and appear as distinct coloured particles or masses. The achromatic network is found in the cell body and the dendrites and is continued also into the axon, where it forms the axial cylinder of the nerve fibre. It consists apparently of delicate threads or fibrillæ, in the meshes of which a homogeneous material, such as is found in cell plasm generally, is contained. In the nerve cells, as in other cells, the plasm is without doubt concerned in the process of cell nutrition. The achromatic fibrillæ exercise an important influence on the axon or nerve fibre with which they are continuous, and probably they conduct the nerve impulses which manifest themselves in the form of nerve energy. The dendritic processes of a multipolar nerve-cell ramify in close relation with similar processes branching from other cells in the same group. The collaterals and the free end of the axon fibre process branch and ramify in association with the body of a nerve cell or of its dendrites. We cannot say that these parts are directly continuous with each other to form an inter-cellular network, but they are apparently in apposition, and through contact exercise influence one on the other in the transmission of nerve impulses. There is evidence to show that in the nerve cell the nucleus, as well as the cell plasm, is an effective agent in nutrition. When the cell is functionally active, both the cell body and the nucleus increase in size (Vas, G. Mann, Lugaro); on the other hand, when nerve cells are fatigued through excessive use, the nucleus decreases in size and shrivels; the cell plasm also shrinks, and its coloured or chromophile constituent becomes diminished in quantity, as if it had been consumed during the prolonged use of the cell (Hodge, Mann, Lugaro). It is interesting also to note that in hibernating animals in the winter season, when their functional activity is reduced to a minimum, the chromophile in the plasm of the nerve cells is much smaller in amount than when the animal is leading an active life in the spring and summer (G. Levi). When a nerve cell has attained its normal size it does not seem to be capable of reproducing new cells in its substance by a process of karyokinesis, such as takes place when young cells arise in the egg and in the tissues generally. It would appear that nerve cells are so highly specialised in their association with the evolution of nerve energy, that they have ceased to have the power of reproducing their kind, and the metabolic changes both in cell plasm and nucleus are needed to enable them to discharge their very peculiar function. Hence it follows that when a portion of the brain or other nerve centre is destroyed the injury is not repaired by the production of fresh specimens of their characteristic cells, as would be the case in injuries to bones and tendons. In our endeavours to differentiate the function of the nucleus from that of the cell plasm, we should not regard the former as concerned only in the production of young cells, and the latter as the exclusive agent in growth, nutrition, and, where gland cells are concerned, in the formation of their characteristic products. As regards cell reproduction also, though the process of division begins in the nucleus in its chromosome constituents, the achromatic figure in the cell plasm undoubtedly

plays a part, and the cell plasm itself ultimately undergoes cleavage. A few years ago the tendency amongst biologists was to ignore or attach but little importance to the physiological use of the nucleus in the nucleated cell, and to regard the protoplasm as the essential and active constituent of living matter; so much so, indeed, was this the case that independent organisms regarded as distinct species were described as consisting of protoplasm destitute of a nucleus; also that scraps of protoplasm separated from larger nucleated masses could, when isolated, exhibit vital phenomena. There is reason to believe that a fragment of protoplasm, when isolated from the nucleus of a cell, though retaining its contractility and capable of nourishing itself for a short time, cannot increase in amount, act as a secreting structure, or reproduce its kind: it soon loses its activity, withers, and dies. In order that these qualities of living matter should be retained a nucleus is by most observers regarded as necessary (Nussbaum, Gruber, Haberlandt, Korschelt), and for the complete manifestation of vital activity both nucleus and cell plasm are required.

### BACTERIA.

The observations of Cohn, made about 30 years ago, and those of De Bary shortly afterwards, brought into notice a group of organisms to which the name "bacterium" or "microbe" is given. They were seen to vary in shape: some were rounded specks called cocci, others were straight rods called bacilli, others were curved or spiral rods, vibrios or spirillæ. All were characterised by their extreme minuteness, and required for their examination the highest powers of the best microscopes. Many bacteria measure in their least diameter not more than $\frac{1}{25000}$th of an inch, $\frac{1}{10}$th the diameter of a human white blood corpuscle. Through the researches of Pasteur, Lord Lister, Koch, and other observers bacteria have been shown to play an important part in nature. They exercise a very remarkable power over organic substances, especially those which are complex in chemical constitution, and can resolve them into simpler combinations. Owing to this property some bacteria are of great economic value and without their agency many of our industries could not be pursued; others again, and these are the most talked of, exercise a malign influence in the production of the most deadly diseases which afflict man and the domestic animals.

Great attention has been given to the structure of bacteria and to their mode of propagation. When examined in the living state and magnified about 2000 times, a bacterium appears as a homogeneous particle, with a sharp definite outline, though a membranous envelope or wall, distinct from the body of the bacterium, cannot at first be recognised, but when treated with reagents a membranous envelope appears, the presence of which without doubt gives precision of form to the bacterium. The substance within the membrane contains granules which can be dyed with colouring agents. Owing to their extreme minuteness it is difficult to pronounce an opinion on the nature of the chromatine granules and the substance in which they lie. Some observers regard them as nuclear material, invested by only a thin layer of protoplasm, on which view a bacterium would be a nucleated cell. Others consider the bacterium as formed of protoplasm containing granules capable of being coloured, which are a part of the protoplasm itself and not a nuclear substance. On the latter view bacteria would consist of cell plasm enclosed in a membrane and destitute of a nucleus. Whatever be the nature of the granule-containing material each bacterium is regarded as a cell, the minutest and simplest living particle capable of an independent existence that has yet been discovered. Bacteria cells, like cells generally, can reproduce their kind. They multiply by simple fission, probably with an ingrowth of the cell wall, but without the karyokinetic phenomena observed in nucleated cells. Each cell gives rise to two daughter cells, which may for a time remain attached to each other and form a cluster or a chain, or they may separate and become independent isolated cells. The multiplication, under favourable conditions of light, air, temperature, moisture, and food, goes on with extraordinary rapidity, so that in a few hours many thousand new individuals may arise from a parent bacterium.

Connected with the life-history of a bacterium cell is the formation in its substance, in many species and under certain conditions, of a highly refractile shiny particle called a "spore." At first sight a spore seems if it were the nucleus of the bacterium cell, but it is not always present when multiplication by cleavage is taking place and when present it does not appear to take part in the fission. On the other hand, a spore, from the character of its envelope, possesses great power of resistance, so that dried bacteria, when placed in conditions favourable to germination, can through their spores germinate and resume an active existence. Spore formation seems, therefore, to be a provision for continuing the life of the bacterium under conditions which, if spores had not formed, would have been the cause of its death. The time has gone by to search for the origin of living organisms by a spontaneous aggregation of molecules in vegetable or other infusions or from a layer of formless primordial slime diffused over the bed of the ocean. Living matter during our epoch has been, and continues to be, derived from pre-existing living matter, even when it possesses the simplicity of structure of a bacterium, and the morphological unit is the cell.

[Sir William Turner then referred to the structure and development of the tissues and organs, and mentioned the names of those who had been foremost in the study of this subject. Such were Wolff, Hofmeister, Julius von Sachs, William Bowman, F. M. Balfour, and the veteran Albert von Kölliker who still lives. General morphology, which must be studied along with the origin and structure of tissues, had among those who had worked at it such thinkers as Goethe, Richard Owen, Reichert, Ralke, and Huxley. Sir William Turner continued:]

The morphological characters exhibited by a plant or animal tend to be hereditarily transmitted from parents to offspring and the species is perpetuated. In each species the evolution of an individual, through the developmental changes in the egg, follows the same lines in all the individuals of the same species which possess, therefore, in common the features called specific characters. The transmission of the characters is due, according to the theory of Weismann, to certain properties possessed by the chromosome constituents of the segmentation nucleus in the fertilised ovum, named by him the germ plasm, which is continued from one generation to another and impresses its specific character on the egg and on the plant or animal developed from it. The special tissues which build up the bodies of the more complex organisms are evolved out of cells at first simple in form. During the evolution of the individual, cells become modified or differentiated in structure and function, and so long as the differentiation follows certain prescribed lines the morphological characters of the species are preserved. We can readily conceive that, as the process of specialisation is going on, modifications or variations in groups of cells and the tissues derived from them, notwithstanding the influence of heredity, may in an individual diverge so far from that which is characteristic of the species as to assume the arrangements found in another species, or even in another order. Anatomists had, indeed, long recognised that variations from the customary arrangement of parts occasionally appeared and they described such deviations from the current descriptions as irregularities.

### DARWINIAN THEORY.

The signification of the variations which arise in plants and animals had not been apprehended until a flood of light was thrown on the entire subject by the genius of Charles Darwin, who formulated the wide-reaching theory that variations could be transmitted by heredity to younger generations. In this manner he conceived new characters would arise, accumulate, and be perpetuated which would in the course of time assume specific importance. New species might thus be evolved out of organisms originally distinct from them, and their specific characters would in turn be transmitted to their descendants. By a continuance of this process new species would multiply in many directions, until at length from one or more originally simple forms the earth would become peopled by the infinite varieties of plant and animal organisms which have in past ages inhabited, or do at present inhabit, our globe. The Darwinian theory may therefore be defined as heredity modified and influenced by variability. It assumes that there is an heredity quality in the egg which, if we take the common fowl for an example, shall continue to produce similar fowls. Under conditions, of which we are ignorant, which occasion molecular changes in the cells and tissues of the developing egg, variations might arise in the first instance probably slight, but becoming intensified in successive generations until at length the

descendants would have lost the characters of the fowl and have become another species. No precise estimate has been arrived at, and, indeed, one does not see how it is possible to obtain it, of the length of years which might be required to convert a variation capable of being transmitted into a new and definite specific character.

The circumstances which according to the Darwinian theory determined the perpetuation by hereditary transmission of a variety and its assumption of a specific character depended, it was argued, on whether it possessed such properties as enabled the plant or animal in which it appeared to adapt itself more readily to its environment—i.e., to the surrounding conditions. If it were to be of use the organism in so far became better adapted to hold its own in the struggle for existence with its fellows and with the forces of nature operating on it. Through the accumulation of useful characters the specific variety was perpetuated by natural selection so long as the conditions were favourable for its existence and it survived as being the best fitted to live. In the study of the transmission of variations which may arise in the course of development it should not be too exclusively thought that only those variations are likely to be preserved which can be of service during the life of the individual, or in the perpetuation of the species, and possibly available for the evolution of new species. It should also be kept in mind that morphological characters can be transmitted by hereditary descent, which, though doubtless of service in some bygone ancestor, are in the new conditions of life of the species of no physiological value. Our knowledge of the structural and functional modifications to be found in the human body, in connexion with abnormalities and with tendencies or predisposition to diseases of various kinds, teaches us that characters which are of no use, and, indeed, detrimental to the individual, may be hereditarily transmitted from parents to offspring through a succession of generations.

Since the conception of the possibility of the evolution of new species from pre-existing forms took possession of the minds of naturalists, attempts have been made to trace out the lines on which it has proceeded. The first to give a systematic account of what he conceived to be the order of succession in the evolution of animals was Ernst Haeckel of Jena, in a well-known treatise. Memoirs on special departments of the subject, too numerous to particularise, have subsequently appeared. The problem has been attacked along two different lines: the one by embryologists, of whom may be named Kowalewsky, Gegenbaur, Dohrn, Ray Lankester, Balfour, and Gaskell, who with many others have conducted careful and methodical inquiries into the stages of development of numerous forms belonging to the two great divisions of the animal kingdom. Invertebrates, as well as vertebrates, have been carefully compared with each other in the bearing of their development and structure on their affinities and descent, and the possible sequence in the evolution of the vertebrata from the invertebrata has been discussed. The other method pursued by palæontologists, of whom Huxley, Marsh, Cope, Osborne, and Traquair are prominent authorities, has been the study of the extinct forms preserved in the rocks and the comparison of their structure with each other and with that of existing organisms. In the attempts to trace the line of descent the imagination has not infrequently been called into play in constructing various conflicting hypotheses. Though from the nature of things the order of descent is, and without doubt will continue to be, ever a matter of speculation and not of demonstration, the study of the subject has been a valuable intellectual exercise and a powerful stimulant to research.

We know not as regards time when the fiat went forth, "Let there be Life, and there was Life." All we can say is that it must have been in the far-distant past, at a period so remote from the present that the mind fails to grasp the duration of the interval. Prior to its genesis our earth consisted of barren rock and desolate ocean. When matter became endowed with life, with the capacity of self-maintenance and of resisting external disintegrating forces, the face of nature began to undergo a momentous change. Living organisms multiplied, the land became covered with vegetation, and multitudinous varieties of plants, from the humble fungus and moss to the stately palm and oak, beautified its surface and fitted it to sustain higher kinds of living beings. Animal forms appeared, in the first instance simple in structure, to be followed by others more complex, until the mammalian type was produced. The ocean also became peopled with plant and animal organisms, from the microscopic diatom to the hugh leviathan. Plants and animals acted and reacted on each other, on the atmosphere which surrounded them, and on the earth on which they dwelt, the surface of which became modified in character and aspect. At last Man came into existence. His nerve-energy, in addition to regulating the processes in his economy which he possesses in common with animals, was endowed with higher powers. When translated into psychical activity it has enabled him throughout the ages to progress from the condition of a rude savage to an advanced stage of civilisation; to produce works in literature, art, and the moral sciences which have exerted, and must continue to exert, a lasting influence on the development of his higher being; to make discoveries in physical science; to acquire a knowledge of the structure of the earth, of the ocean in its changing aspects, of the atmosphere and the stellar universe, of the chemical composition and physical properties of matter in its various forms, and to analyse, comprehend, and subdue the forces of nature. By the application of these discoveries to his own purposes man has, to a large extent, overcome time and space; he has studded the ocean with steamships, girdled the earth with the electric wire, tunnelled the lofty Alps, spanned the Forth with a bridge of steel, invented machines and founded industries of all kinds for the promotion of his material welfare, elaborated systems of government fitted for the management of great communities, formulated economic principles, obtained an insight into the laws of health, the causes of infective diseases, and the means of controlling and preventing them.

When we reflect that many of the most important discoveries in abstract science and in its applications have been made during the present century, and indeed since the British Association held its first meeting in the ancient capital of your county 69 years ago, we may look forward with confidence to the future. Every advance in science provides a fresh platform from which a new start can be made. The human intellect is still in process of evolution. The power of application and of concentration of thought for the elucidation of scientific problems is by no means exhausted. In science is no hereditary aristocracy. The army of workers is recruited from all classes. The natural ambition of even the private in the ranks to maintain and increase the reputation of the branch of knowledge which he cultivates affords an ample guarantee that the march of science is ever onwards, and justifies us in proclaiming for the next century, as in the one fast ebbing to a close, that great is science and it will prevail.

# A Clinical Lecture

ON

# THE EXPECTANCY OF LIFE IN CASES OF CANCER OF THE BREAST.

*Delivered at University College Hospital on July 14th, 190*

BY ARTHUR E. BARKER, F.R.C.S. ENG.,

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF SURGERY AT UNIVERSITY COLLEGE AND SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

GENTLEMEN,—The gloom which has hung over the question of the expectancy of life in cancer of the breast has hitherto been fully justified. We know from the experience of the older surgeons that the majority of women afflicted with this disease are doomed if untreated by operation to death within two years. And even those who in former years submitted to the removal of the breast for this disease in most cases suffered from speedy local or general recurrence. But within the last few years some rays of hope have been cast upon this dark chapter of surgery by the achievements reported in various directions of the results of more recent and improved operations. At the present moment the outlook of a woman with cancer of the breast is

by no means so desperate as, say, 20 years ago, either as regards the prospect of prolongation of life by operation or complete immunity from recurrence. This is due to many causes operating together and reacting one upon the other. Before all things it depends upon the spread of knowledge among the general population and the profession in regard to the danger of neglecting any tumour of the breast. This is as much as to say that the knowledge of the pathology of breast carcinoma is more accurate and general than in earlier days. The particular way in which this more general diffusion of knowledge has influenced our results can perhaps be most briefly expressed by putting before you some of the axioms now pretty generally received in relation to this question.

In the first place, our pathological knowledge is now much more accurate than formerly in regard to the commencement and mode of dissemination of cancer of the breast. The following are the pathological axioms which most directly influence our surgical practice in dealing with the disease. 1. Carcinoma of the breast is probably for a short time a purely local disease. 2. It very soon begins to spread from the primary focus into the surrounding tissues by way of the lymphatics. 3. Three systems of lymphatics participate in this process—the epi-mammary under the skin, the mammary in the breast substance, and the sub-mammary in the fascia covering the pectoral muscles. 4. The lymphatic glands of the axilla receive most of the lymph and cancer germs from these systems and act as a dam to their further progress for a time. In some rarer cases the flow of lymph takes place—in part, at all events, towards the lymph-channels underlying the pleura. 5. It is probably possible to reinfect otherwise healthy tissues during an excision of the breast by the juices of the infected material in process of removal. This may take place either by the knife or other instruments, the surgeon's hands, or by actual contact of a cut surface of the infected area with the dissected surface. 6. When the cancerous infection has reached the underlying muscles it usually corresponds with a spread to the internal organs.

Bearing these points in mind the following surgical axioms have come to be pretty generally held and acted on in the operative treatment of the disease with great advantage to the patient. 1. An excision of the breast to be effectual must be early. 2. The overlying skin, subcutaneous fat, pectoral fascia, axillary fat and glands with the entire breast must be widely and deliberately removed. 3. During this dissection all division of carcinomatous tissue should be avoided and if inevitable freshly sterilised instruments, &c., must be used. 4. As little direct handling of the parts to be removed as possible should take place. 5. Arrest of all immediate bleeding should be accomplished preferably by forcipressure, and if not by ligature and subsequent oosing by elastic pressure and bandaging. Rest for the wound and the patient should be secured for at least two weeks. 6. All this extensive removal can be accomplished with but little risk to the patient in fairly early cases. 7. When the disease has infected the muscles palliation alone can be expected from surgical interference, and it is questionable whether very extensive operations involving risk from shock ought to be performed with only this end in view. Indeed, the apparently paradoxical rule (which for my own part I have followed of late) appears to be justified—viz., that the more localised the primary focus of carcinoma in the breast is the more wide reaching should be the excision on the above lines. That is to say, there is in such cases a fair prospect of complete eradication of the disease by a wide-reaching operation, and therefore it is justifiable to run some risk of shock. The converse rule appears also to have much to recommend it—viz., that the more wide reaching the disease the more clearly should the operator keep mere palliation in view and by limiting his operation avoid the risk of extreme shock.

These considerations at all events have materially influenced my own practice of late years and I should now like to place before you the results of 100 consecutive excisions of the breast which I have done. They have been carefully analysed by a brilliant former student, Mr. J. E. Simpson, in his Liston Prize Essay for 1898, and I have only for your benefit to-day brought the record down to date which he had hoped to do had he lived. He spared no pains to make the analysis accurate by looking up the patients and examining the documents in the Registrar-General's office at Somerset House, and his industry and ability are known to us all. The first point he examined into was the nature of the disease for which excision was performed. The following were his results:—

| Nature of tumour. | Number of cases. | Nature of tumour. | Number of cases. |
|---|---|---|---|
| Scirrhus ... ... ... ... | 82 | Cystic adenoma... ... | 1 |
| Colloid cancer ... ... | 2 | Duct papilloma ... ... | 1 |
| Scirrho-encephaloid ... | 2 | Chronic fibrosis ... ... | 1 |
| Duct cancer ... ... ... | 4 | Doubtful ... ... ... | 1 |
| Cystic degeneration ... | 4 | | |
| Fibro-adenoma ... ... | 2 | Total ... ... ... | 100 |

This gives us a proportion of 90 malignant cases to nine of non-malignant and one doubtful.

The next point studied was the gross mortality in 100 excisions. This comes out as follows, and you will notice that the deaths fall mostly to the earlier years when procedures were far less perfect than of late.

| No. of cases. | Cause of death. | Date of death. |
|---|---|---|
| 1 | Pyæmia. | 1878—3 months after operation. |
| 1 | Septicæmia. | 1880—1 month ,, ,, |
| 1 | Cellulitis. | 1888—8 days ,, ,, |
| 1 | Syncope. | 1894—9 ,, ,, ,, |
| 1 | Pleurisy. | 1895—4 ,, ,, ,, |

The first three of this group of deaths from operation would probably not appear in any subsequent series of cases so much has been the improvement in wound treatment since 1888. The mortality, therefore, to-day is probably far below this 5 per cent. But such cases as that of syncope occurring in an old lady on the eighth day when the wound was perfectly healed per primam belong to the accidents of our experience against which we cannot be shielded by any amount of care. In the case of pleurisy there was no injury of the pleura so that the cause was probably the exposure in a feeble woman. Leaving out the cases of so-called duct cancer as perhaps not strictly carcinoma there remain 86 cases of undoubtedly malignant character, including scirrhus (82), colloid (2), and scirrho-encephaloid (2). These I have grouped in the following tables in a way which gives us some idea as to the "expectancy of life in cancer of the breast."

TABLE I.—*Cases known to have Died long after Excision, presumably from Recurrence, though one case certainly died from Calculous Pyelitis without Recurrence, and possibly others.*

| | | | |
|---|---|---|---|
| Lived over 7 years ... | 1 | Lived over 2 years ... ... ... | 14 |
| ,, ,, 6 ,, ... | 3 | ,, ,, 1 ,, ... ... ... | 14 |
| ,, ,, 5 ,, ... | 1 | ,, under 1 ,, ... ... ... | 10 |
| ,, ,, 4 ,, ... | 2 | | |
| ,, ,, 3 ,, ... | 7 | Total ... ... ... ... ... | 52 |

(Lived over 7 years to over 3 years: 14 = 26·9 per cent.)

It is evident from this that 26·9 per cent. have lived over three years and yet succumbed to cancer. Mr. Simpson traced a further nine cases for over three years, but found no record of death in any.

Here we see that 52 cases have died within intervals ranging from two months to over seven years. In Table II. you have 20 cases known to be alive at the intervals given; and of these 15 are or were alive over three years.

TABLE II.—*Cases of Excision of the Breast known to be Alive at the Intervals given in July, 1900, grouped with those Alive and without Recurrence respectively 10 years and one month, one year and seven months, and one year and two months when last heard of more than a year ago.*

| | | | |
|---|---|---|---|
| Living after 14 years ... ... | 1 | Living after 2 years ... ... ... | 3 |
| ,, ,, 10 ,, ... ... | 1 | ,, ,, 1 ,, ... ... ... | 2 |
| ,, ,, 8 ,, ... ... | 2 | | |
| ,, ,, 7 ,, ... ... | 1 | Total ... ... ... ... ... | 20 |
| ,, ,, ,, ... ... | 3 | | |
| ,, ,, ,, ... ... | 1 | | |
| ,, ,, 4 ,, ... ... | 3 | | |
| ,, ,, ,, ... ... | 3 | | |

(Living after 14 years to over 3 years: 15)

TABLE III.—*Cases known to have Died taken together with those still Alive and Examined as to Duration of Life.*

| | | | |
|---|---|---|---|
| Lived over 13 years | 1 | | |
| ,, ,, 10 ,, | 1 | | |
| ,, ,, 8 ,, | 2 | | |
| ,, ,, 7 ,, | 2 | = 14 = 16·2 per cent. | |
| ,, ,, 6 ,, | 6 | | |
| ,, ,, 5 ,, | 2 | | |
| ,, ,, 4 ,, | 5 | = 29 = 33·7 per cent. | |
| ,, ,, 3 ,, | 10 | | |
| ,, ,, 2 ,, | 1 | | |
| Lived over 1 year | 16 | | |
| | 62 | | |
| ,, ,, 1 month | 10 | | |
| | 72 | | |
| Untraced | 9 | | |
| | 81 | | |
| Died from operation | 5 | | |
| | 86 | | |

From this it will be seen that 16 per cent. lived over five years and 33·7 per cent. over three years. These figures appear to justify the hope that the expectancy of life is improving as time goes on. It is clear that over 33 per cent. live more than three years after the operation, which has suggested to some surgeons that such cases should be regarded as permanent cures. But some of the cases (26·9 per cent.) have died most likely from recurrence in all but one after an interval of immunity of over three years, so that such a presumption is unwarranted.

Another interesting point comes out from this analysis—namely, that only seven suffered from *local* recurrence. Those in whom the disease has returned have shown it in internal parts. This is another good feature of the modern operations, local recurrence being most depressing and painful, while internal generalisation is often not so.

These cases have been accurately recorded and in almost every case the diagnosis with the naked eye has been confirmed by microscopical examination by various competent observers, mostly the hospital registrars. In the oldest case in the list the glands were extensively invaded as well as the breast, and a bad prognosis was given at the end of the operation, and yet at the end of 14 years the patient is well and free from any trace of cancer. This and some of the other cases seem to justify the hope that this disease can be eradicated by the knife. And it is not too much to hope that with still further improvement in early diagnosis and treatment a far larger proportion of cases may be saved. If the four cases of duct cancer were included the figures would be still more favourable.

## ON THE PATHOLOGY AND THERAPY OF ANGINA PECTORIS.

BY PROFESSOR THEODOR SCHOTT, M.D.

AMONG chronic diseases of the heart angina pectoris has in the passing century attracted the interest of the medical profession in a remarkable manner. Ever since the first excellent description by Heberden appeared more than 100 years ago the various theories advanced as to the nature and the causes of stenocardiac accesses have been in sharp opposition. This may be explained in great part by the fact that, as Latham justly remarks, angina pectoris must be regarded not as a disease *sui generis* but as a series of symptoms. Even, however, in regard to angina pectoris vera—to which the following observations are exclusively directed—opinions still remain unsettled and divided. The hypothesis of Heberden and of Latham that the anginal fit is to be regarded as a real tetanic contraction of the cardiac muscle has found at different times a varying number of adherents. A tetanic cramp of the whole cardiac wall would, if it prevailed but a short time, certainly destroy human life; but a tetanic contraction of a part of the heart might take place without deadly result, as has been demonstrated latterly by experiments of Basch and Grossmann. In direct opposition, however, is the theory of Parry which has been effectively supported by the celebrated Stokes. According to this opinion angina pectoris must be attributed, not to an increase but to a further reduction of the muscular energy of a heart already enfeebled. According to Parry the stenocardia is a sort of syncope with a preceding strong oppression or pain in or near the heart, the consequence of an organic lesion the effects of which are brought into evidence by a lowering of heart power. Thus Parry opines that the symptoms are caused by an accumulation of blood in the cardiac cavities. This explanation has been powerfully supported in Germany by the well-known Professor Traube, an authority on the subject of heart diseases. Traube also believes that there is loss of power of the heart muscle, but he thinks that the access results from a rapidly increasing tension of the walls of the ventricles under the influence of an accelerated over-filling of the cardiac cavities, in consequence of which the motor as well as the sensor nerves of the heart respectively are subjected to a degree of pressure or tension sufficient to account for the sudden pain. Samuelson, whose experiments are founded upon an artificial constriction of the coronary vessels, differs from Traube only in that he supposes the over-filling of the heart to take place, not in the left ventricle but in the right auricle. French physicians, such as Potain, Germain Sée, and others, attribute the attack to an ischæmic state of the cardiac muscle, attributing the pains to causes similar to those observed when there is a blocking of the arteries as in endarteritis obliterans and in similar processes. But the ischaemic state of the cardiac muscle may be taken to induce a weakness of the organ, so that this theory agrees in the main with that of Parry and Stokes. Although the latter view commands a majority of adherents—as may be gathered, for example, from the opinion expressed at the meetings of the London medical societies—it has always found opponents as at the Congress of Internal Medicine at Wiesbaden (1891) where Vierordt, one of those who opened the discussion, revived the question whether the stenocardiac fit is really dependent on debility of the heart. The principal argument for that doubt is that the pulse does not of necessity show any corresponding change—that there may be no diminution of volume—that in some cases, indeed, it becomes stronger. Another argument is that manifest signs of weakness of the heart are not invariably discoverable.

Before we discuss these theories let us consider what processes are found to be associated with angina pectoris vera. They are, in the first place, sclerosis of the coronary vessels, alterations of the aortic valves, and aortitis, especially that form which causes an ectasia of the ascending portion. (In a case of angina pectoris combined with insufficiency of the mitral valve which has been under my treatment these three years I observed latterly the development of an aortic stenosis; so that also in this case, though there are no signs of rigidity of the vessels, the sclerotic process at the heart cannot be regarded as doubtful. I may add that latterly I have seen several similar cases.) It is known, however, that the sclerotic change in just this part of the aorta is not without an influence on that spot from which the coronary vessels take their origin, and not seldom it may be noted post mortem that, though the other parts of the coronary arteries still show a sufficient lumen it is reduced at the point referred to in such a degree that a bristle can scarcely be introduced. The next consequence of such an arterial change must be that as a result of decreased circulation the muscles of the heart are no longer adequately nourished. Weakening of the heart and defect of energy follow of necessity. Moreover in the stenocardia of angina pectoris vasomotoria—the pseudo angina resulting from so many different causes may be left aside—the heart is called on to exert itself against a contracted arterial system, so that in such cases, also, there is a sufficient cause for a sudden relative weakness of the heart. The conditions calculated to induce a weakening of the heart are apparently present in both instances, and it is easy to understand that every demand for additional effort is likely to be followed by an additional, as well as sudden, failure of energy. The suddenness of the paroxysm may be also directly attributable to the retardation of the circulation within the coronary vessels. A moderate distension of the cardiac muscle may easily lead to a temporary occlusion of one or more coronary vessels at the seat of an already existing constriction. In other cases a thrombus or an embolus are the cause of the block, and we know that such vascular conditions give rise to violent as well as sudden pain in other parts of the muscular system. The experiments of Samuelson, of Cohnheim, of Schultess-Reihberg, and of many others have furnished sufficient evidence of this.

Let us now inquire whether clinical observation lends confirmation to what has been suggested. I restrict myself to my own experience, and I would in the first place

emphasise the fact that I never could observe any absolutely characteristic or invariable condition of the circulatory system before, during, or after the accesses. Let us look first to the state of the pulse. For that purpose we must not entirely depend on digital examination—we must have recourse to the sphygmograph and the sphygmomanometer. How often do we recognise by means of these instruments that, for instance, a bradycardia, which actually exists in some instances, is in a number of others only apparent, and that the sphygmograph discloses a number of pulsations which are not appreciable by the finger so that the apparent bradycardia may be an actual tachycardia. In other cases we meet with a real tachycardia or an intermittent or arhythmic pulse. That the volume of the pulse very often appears reduced is well known. With a large number of patients I have noted reduction of the pressure of the pulse during the attacks. The latter observation is especially applicable to the pulsus celer, the tension of which is frequently apt to lead to mistakes.

We will now proceed to the examination of the heart itself. In the earliest stages of this cardiac disease it is frequently very difficult to certify to difference in the strength and character of the heart's sounds in the intervals between the attacks as compared with those of unimpaired health. There are other cases in which the contrast becomes rapidly apparent. It will not, however, escape the attention of a practitioner who has occasion to observe such patients for a long period that heart-sounds become feebler during the fits; in other cases the sounds become dull or impure and distinct murmurs are observable, and not rarely I have convinced myself that the rhythm assumes the character of a gallop. Less frequently the beatings of the heart become fœtal or fluttering.

Evidence still more demonstrable may be obtained by percussion.[1] The limits of dulness have been accurately traced with a solution of nitrate of silver. The following may be observed more or less definitely according to the progress of the disease. In the beginning there is a moderate dilatation which affects especially the left side. For a time the left auricle may be more distended than the corresponding ventricle. If the malady advances the heart becomes more and more distended; the right side becomes involved, but the left ventricle remains more permanently dilated until finally the whole heart is and remains enlarged. In such cases—that is, those in which the limits of the heart fail to recede to a normal state—we note that with the stenocardia there co-exist the other indications of a cardiac dilatation with consequent incompetence, such as breathlessness, &c., but the characteristic feature which is attested by percussion at the beginning of the disease is debility of the left heart. It has been a satisfaction to me to be able to confirm these results of percussion by means of the x-rays, which supply an important additional resource for physical examination. I had an opportunity last year when I made a number of experiments with Roentgen rays in cases of cardiac muscular diseases, not only to examine with the fluorescent screen but to take a radiogram of a man 40 years of age at the very moment in which he became subject to an anginal fit. This patient had in former years consumed quantities of beer and of effervescent waters. Seven years ago he was visited by his first attack of gout. Since that time he has had frequent attacks of podagra and gonagra. The last one took place a fortnight before the examination in question. At the left elbow, for some weeks, a tophus had been apparent. The first attacks of oppression were felt while bicycling; later, palpitations and breathlessness were induced by over-exertion. Within the last few months the oppression in the chest increased and was accompanied by radiating pains in the left arm and fingers. The stenocardiac fits were most observable in cold weather, especially during the prevalence of cold winds and fogs, so much so that he was brought to a standstill in the streets. Latterly his medical adviser was able distinctly to note a cardiac dilatation. The urine had a specific gravity of 1015 and showed a trace of albumin but no casts.

In a former paper[2] I drew attention to the fact that with the help of leaden discs fixed to both the nipples, we are able to ascertain whether the patient has maintained under examination the same distance from the photographic plate (as well as from the fluorescent screen) to the Roentgen tube. It must be especially noted that the anginal attacks are readily excited by bodily exertion and by mental excitement. A somewhat accelerated pace, the ascent of even a slight incline, even the act of turning round in bed or breathing in cold wind or fog may suffice to cause a stenocardiac fit, acts which, however insignificant they may be, require a somewhat increased effort on the part of the heart. Under favourable conditions and especially in a state of absolute rest these accesses generally soon subside. The etiology of the affection is too well known to need special description, but it must not be forgotten that inheritance plays a prominent part in the causation of this disease. I myself have observed a good number of cases in which several individual members of one family have suffered from angina pectoris.

It now remains to consider the therapy of this disease, and in doing so we shall, I think, discover from further evidence the correctness of the Parry-Stokes theory. Setting aside prophylaxis the treatment may be considered under two heads—viz.: (1) the therapy of the anginal fit itself; and (2) the treatment of the heart in the intervals between attacks. The actual paroxysms are most efficaciously relieved by the nitrites, and on that subject the publications of Sir William Broadbent, Sir T. Lauder Brunton, &c., are so well known that I scarcely need to enter into further details. Nitro-glycerine is in most cases superior to the nitrite of amyl, as its effect is mostly more prompt and intense. I decidedly prefer the liquid form to the tabloids on account of the more rapid effect and the facility of accurate dosage, but we know that inhalations of the nitrite of amyl prove successful in some cases in which nitro glycerine fails to relieve. My experience of the use and value of the tetranitrate of erythrol is not sufficiently extensive to justify the expression of a decided opinion. Nitro-glycerine in suitable cases frequently produces striking effects, but without doubt its application requires much caution and experience and constant medical supervision, as, in default of these safeguards, collapse is only too likely to occur. Antipyrin, formerly much used by the French and especially by Germain Sée, has more and more lost its advocates, not only because of its more or less questionable efficiency, but also on account of its being a source of some danger to the patient. The paroxysm of pain may also be relieved by the application of external measures such as friction with spirit of wine (I prefer hot spirit of wine with an addition of salt), mustard spirit, or the application of mustard leaves, &c. But most efficacious have I found the application of heat, and for that purpose I have designed a special india-rubber bag provided with a thermometer in such a manner that the temperature of the water may be measured and regulated at any moment. Moving the bag at a temperature of from 140° to 170° F. with light touches over the whole chest effects, in a good number of cases, either marked relief or the absolute suppression of the pains.

In a number of cases, however, we must expect to be disappointed by the above-mentioned remedies and be prepared for the pains to become so intense that we shall be forced to have recourse to narcotics. Before all others stands morphine, but even where it becomes indispensable it is advisable not to bring it into continuous use. It is preferable to give single considerable doses and, if necessary, to administer it subcutaneously. The injurious effect on the heart of the prolonged use of morphine may be regarded as generally admitted. In iodine we have a medicament which is to be used as well during the fits as during their intervals. As all salts of potassium are more or less detrimental to the heart, and as in cases of angina pectoris vera we have to apprehend a failure of power, I always prescribe the iodide of sodium, which in view of the irritating effects of salts of iodine on the mucous membranes, including that of the digestive organs, is best exhibited in milk. In a series of cases it has proved very useful even where no antecedent syphilitic taint existed; in others it was not followed by good effect, but this remedy also ought not to be given for a long-continued period and particularly not if given in increasing doses. Especially will it be necessary carefully to watch the weight of the body, as all the salts of iodine are apt to destroy the molecules of albumin and thereby to cause more injury than any benefit that can accrue.

In the intervals of the attacks and indeed often in the course of the attacks we must take measures to stimulate the heart and to strengthen it. As stimulants we especially

[1] I avail myself of the method of my late brother, August Schott—that is, a percussion with limitation, by which we are enabled to percuss the anatomical limits of the heart. This is a fact which amongst others I have often demonstrated before several medical officers of the Maison de Santé at Berlin.

[2] Deutsche Medicinische Wochenschrift, 1897.

commend ether or camphor and the salts of caffeine. Among the latter I desire to express a caution as to the use of iodio-salicylate, because I have observed that marked relapse is apt to follow the use of that remedy, whereas the sodio-benzoate and the citrate appear to be exempt from that drawback. It is a well-known fact that digitalis fails to relieve much more frequently in cases of angina pectoris vera than in many other diseases of the heart. This applies as much to the uncomplicated forms caused by the sclerosis of the coronary vessels as to those which are combined with aortic valvular lesions or aortitis. We must not, however, undervalue its usefulness to such an extent as has been done latterly in different directions, for, though the pains be little or not at all influenced by its use, we often succeed in obtaining a beneficial effect from this important drug in cases of heart disease. Still less must we rely upon strophanthus which too often is ineffectual; and still less can we trust to inferior remedies such as convallaria majalis, adonis, and such like remedies which need scarcely be mentioned.

In such cases as we are now considering physical therapy proves its value in a most satisfactory way, and the tonic effect of the balneological and gymnastic treatment as described by my late brother and myself becomes most evident. I abstain from recurring to the details of our system and only lay stress upon the importance of much caution in the application of the baths as well as the therapeutic exercises. I would especially express a warning against hurrying on to strong effervescent baths and especially to the strongest form of the effervescent running baths. Besides, more harm than benefit would be derived from baths either too cool or too warm. Very rarely are we allowed to go below 85° or to rise above 93° F., nay, even from a temperature of 95° I have now and then observed unfavourable effects. Moreover a long immersion is not advisable. I mostly limit it to the space of 15 minutes and rarely extend it to 20 minutes. Similar precautionary measures are to be observed with regard to exercises. The resistance must not be very strong, the pauses between the exercises must not be too short, and the patient must never be suffered to exert himself till fatigued. A sufficient interval of rest after the exercises is under all circumstances important.

In a series of articles I have shown in past years the results of the balneological and gymnastic treatment especially in cases in which rest as well as pharmaceutic remedies proved useless. Recently their efficacy has been attested by many authorities. In response to inquiries lately addressed to me I should be glad to state that the treatment by baths and exercises has proved to be of signal success even in cases in which the nitrites, and principally nitro-glycerine, had more or less failed. I would especially refer to a treatise by Rives.[3] Rives had the opportunity of observing at Nauheim a patient who was under my treatment and had been sent to me by Sir T. Lauder Brunton. He came from Karachi, was aged 53 years, and was subject to so many stenocardiac fits that in the first few days of his stay at Nauheim he was obliged to have recourse to as many as 20 tabloids of nitro-glycerine a day. A treatment of 13 weeks caused all symptoms not only to disappear but resulted in a general state of well-being. It deserves to be remarked that this patient continued to enjoy good health until great mental strain induced by the ravages of the plague in his town subjected him again to slight attacks. A renewed treatment in Nauheim of seven weeks in the spring and of five weeks in autumn again had the effect of removing his troubles so that Sir T. Lauder Brunton, on the return of the patient, was able to certify a perfectly normal condition of the heart. I must not omit to mention that with such patients it is necessary to adhere to the same precautionary measures as to diet, exercise in fresh air, dress, &c., as are to be observed with other patients with heart diseases, such as failure of compensation in consequence of valvular lesions, and in myocarditis, &c.

It must, however, be clearly stated that not all cases without exception are suitable for balneological and gymnastic treatment. When arterio-sclerosis has made such progress that the danger of embolism or apoplexy may be apprehended, or where there is reason to believe that there already exists even a small aneurysm of the wall of the heart or the aorta which might favour rupture, it is well known that every increase of the blood-pressure, which is a natural consequence of the above treatment, might lead to the fatal consequences. Rigidity of the vessels or early stages of arterio-sclerosis may be treated by these methods and usually yield satisfactory results, but I must lay stress again upon the fact that advanced sclerosis is a contra-indication for this treatment. As regards the latter state I have raised a note of warning years ago,[4] and my later experience has only strengthened my view on the subject. In such cases strict enforcement of rest is certainly preferable.

Looking, in conclusion, once more at the actual state of our therapeutic experience we are brought to the conclusion that the results which we obtain by the application of the above-mentioned more prominent medicaments is to be explained by the lowering of the pressure of the blood and the moderation of the heart's action consequent upon it. Differing therefrom are the causes which ensure success in the balneological and gymnastic treatment because it is obtained by the exercise of a tonic influence. By strengthening the heart's muscle, as well as by acting on the cardiac nerves, the distressing symptoms of the angina pectoris are either removed or reduced; in other worde, *ex juvantibus*, it is shown that the Parry-Stokes theory is based on a real and solid foundation.

Bad-Nauheim.

## SOME REMARKS UPON THE TREATMENT OF HEART DISEASE, WITH SPECIAL REFERENCE TO THE "HILL HEART."[1]

BY H. J. CAMPBELL, M.D., F.R.C.P. LOND.,

SENIOR PHYSICIAN TO THE BRADFORD ROYAL INFIRMARY AND LECTURER ON FORENSIC MEDICINE IN THE YORKSHIRE COLLEGE, LEEDS.

IN the treatment of most forms of heart disease the difficult problem of how to relieve an organ which has such constant demands made upon it, and which is obliged to rest and recuperate in the brief intervals allowed between its active contractions, is met in one of two ways, the one being the stimulation of the heart, so that by working harder and more efficiently, it may compensate for its own defectiveness, and the other the lessening of the work that the organ has to perform, so that the balance of demand and supply of force may be restored and maintained. In most cases of valvular disease with failing compensation, we of course adopt the two methods of excitation and compensation both at once, combining the exhibition of cardiac stimulants, such as digitalis, strophanthus, convalaria, sparteine, or caffeine, with the diminishing of cardiac work by ordering rest in bed, and the lowering of blood-pressure by the judicious use of purgatives, diuretics, &c.

In the special methods adopted at Nauheim, the same combination of stimulation with alternate lessening of work, explains the marked success of this form of treatment in suitable cases. The effect of the Sprüdel water at a temperature of 95° and charged with carbonic acid, is to cause the peripheral vessels to contract and the blood-pressure consequently to rise, as evidenced by the slowing of the pulse. The result is that the heart has more work to do and therefore has its muscle stimulated to more forcible and complete contraction, with the consequent more thorough emptying of its cavities. After leaving the bath the peripheral vessels dilate, the blood-pressure is lowered, and the resulting diminution of the work the heart has to perform, enables the muscle to maintain its increased state of efficiency. Exactly the same sequence of events occurs with the resisted movements, for here again the first effect is to cause a rise of blood-pressure, shown by the slowing of the pulse, while the second effect of dilatation of the vessels of the muscle lowers blood-pressure and therefore lessens the strain upon the labouring heart. In this respect it is interesting to note that Dr. Schott has demonstrated by the use of the Roentgen rays that the more complete emptying of the heart and the consequent reduction of dilatation under this treatment, is an actual fact and is

[4] THE LANCET, May 23rd, p. 1143, and May 30th, 1891, p. 1199.

[1] A paper read before the Yorkshire Branch of the British Medical Association on March 28th, 1900, at Huddersfield.

not to be explained by better filling of the lungs and consequent diminution of the area of cardiac dulness. The good results of Oertel's method of graduated walking exercises by slow movements, first on the flat and then up inclined planes, are capable of a similar explanation.

All these methods, however, to be successful must have a heart to work upon which has muscle substance capable of either exerting more force under increased stimulation, of increasing its power of contraction as the result of its hypertrophy if the conditions are favourable, or at least of recovering itself if nutrition is abundant, and partial rest gives it time for recuperation. The cases which, from the point of view of treatment, present the most difficulty are those in which, from whatever cause, the muscle substance is degenerated to such an extent that it is unable to react to the means employed for its relief. In such cases, whether the condition is the last stage of disease of the aortic valves, of failure of the right ventricle in old emphysema and bronchitis, or of the left ventricle in granular kidney, all that can be done is to acknowledge that the heart is no longer able to maintain an efficient circulation of the blood in the adverse circumstances in which it is placed, and to endeavour permanently to lessen the work it has to do—that is to say, to alter as far as possible the relationship between the general system and the heart in such a way that the patient may, for a longer or shorter period, enjoy an impaired but still tolerable degree of comfort and health.

There is another class of case, however, and one which is especially common in hilly districts, where there is also no valvular disease, but where the heart muscle is degenerated to an extent which, though not sufficient to incapacitate the patient from following his ordinary avocations or, as a rule, to produce any backward pressure effects, yet, when any sudden strain is thrown upon it, or any interference with its free movements is encountered by it, is apt to give rise to alarming and dangerous attacks. These may only cause distress, dyspnœa, or anginal pain, or they may induce syncope, or even lead to seizures of an epileptiform or apoplectiform character, and may, and not infrequently do, terminate in almost sudden death. The following brief extracts from my notes will serve to point out the main features met with in these cases.

CASE 1.—The patient was a bachelor, aged about 70 years, who had always enjoyed good health, but for the last few years had been unable to walk upstairs so well as formerly and had often had to stop and rest on going up hill. His appetite was good and sleep was not disturbed. During the week before his medical attendant asked me to see him he had had repeated attacks of acute cardiac distress with faintness and a feeling of impending dissolution. He had only been under treatment since these attacks commenced. There was no valvular lesion; the heart beat was fairly forcible and the pulse was regular and not of high tension. All the other organs were healthy. There was no albumin in the urine. During the previous week the patient had suffered from a great deal of flatulence. For two days after seeing the patient there was no attack, then one came on which proved immediately fatal.

CASE 2.—The patient was a man, aged 58 years, who was first seen in May, 1896, and who for several years had had flatulent dyspepsia. On two occasions he had had severe fainting attacks followed by a feeling of great exhaustion necessitating rest in bed and treatment for some weeks. The bowels were confined. The patient looked older than his years and had an anxious expression. He was fairly well nourished, though he stated that lately he had been eating very little in the hope of diminishing the flatulence. On going up hill he often had to stop, not from dyspnœa, but from a feeling of oppression on the chest associated with what he described as a "beating" in the stomach. The heart was considerably enlarged, the apex beat was feeble and somewhat diffused, and the pulse was of low tension and very irregular; no bruits were to be heard and all the other organs were healthy, except the stomach, which was dilated. On a light but nourishing diet and general tonic treatment the patient improved and two months later was put upon sparteine sulphate and nitro-glycerine. The next time I heard about him was nearly two years later when, after a long period of comparative comfort, during which he had not required treatment, he had become careless as to his food and mode of life with the result that all his old symptoms returned. On this occasion it was decided, since the condition was of much shorter duration than on the former one, at once to make use of cardiac tonics and he was given a pill of sparteine sulphate, digitalis, and extract of hyoscyamus once a day. Creasote in mixture was ordered to be taken immediately before meals and he was again put upon a strict diet and directed to move about slowly. 18 months later when seeing another member of the family I casually saw the patient who looked well and said that as long as he was careful he got on all right, a statement that his medical adviser confirmed, but that any small indiscretion upset him.

CASE 3.—For purposes of comparison I may briefly mention the following case. The patient was a man, aged 25 years. Until recently he had been accustomed to be in constant training and to spend most of his time in athletic sports; lately, however, he had given up athletics and had very little exercise. In the course of the previous two weeks he had had three syncopal attacks. He was a healthy-looking, well-developed, well-nourished man. All organs were normal except the heart which was enlarged, with a feeble diffused impulse, a prolonged first and a somewhat accentuated second sound. The pulse was 75 and was feeble. In this case the condition was evidently one of a "soft" heart—that is to say, of a heart in which the muscle, which during training had become hypertrophied to meet the increased strain put upon it, had when the strain was relaxed become flabby. I have not heard from this patient's medical man what the further history of the case was, but I have no doubt that the condition proved to be a purely temporary one.

CASE 4.—In the last case that I propose to mention the patient was a man, about 65 years of age, who had had a similar attack to the one for which I first saw him, some months before. He was a stout, florid man, had always been temperate, and had had remarkably good health all his life. One night he went to bed in his usual health, but early on the following morning he had an attack which was of a convulsive nature but of short duration. When his medical attendant saw him shortly after the attack he had a bounding pulse and was only semi-conscious, with suffused head and face. His medical attendant performed venesection to ten ounces, after which he improved rapidly. At 2 P.M. on the same day, when we saw him together, there were no localising symptoms, he had completely recovered consciousness, and except for headache did not feel as though there were much the matter with him. The treatment consisted in dieting and the administration of nitro-glycerine, under which he soon got about again, but almost every week he had a slight attack which his medical adviser said was not unlike minor epilepsy, but he, however, never lost consciousness. These attacks were specially apt to come on after any excitement or after a full meal. The heart was enlarged and the first sound was thick, but there was no valvular disease. The patient continued in much the same condition until December last, when he had a rather more severe attack, though still without loss of consciousness. The pulse was lower in tension but otherwise the condition was unchanged. Shortly afterwards he had a similar attack which proved fatal.

I have introduced the third case because it explains, I think, why in hilly districts one so frequently meets with the condition illustrated by the other three cases. The history of these cases, I take it, is as follows. A healthy man who is constantly having to go up and down hills, working hard, eating probably somewhat largely, the food, moreover, not always being very easy of digestion, develops cardiac hypertrophy and slight gastric dilatation. As time goes on he probably becomes wealthier and hence most likely takes less exercise, whilst at the same time his food is liable to be richer, although in quantity not materially diminished. If at the same time alcohol be at all freely indulged in, all the circumstances are present which tend to produce dilatation of the stomach and degeneration of the heart walls, the hypertrophied muscle becoming soft and fatty changes occurring in the cells. The stomach, too, which has bravely battled for years with the somewhat large supplies which it has been made to hold, now begins to lose tone and stretch. At the same time the peptic and especially the oxyntic cells become less active and fermentative changes are apt to occur in the food owing to its lying too long in the atonic organ, with the result that gases are evolved which still further tend to increase the distension. There is probably, too, less room for the stomach to expand downwards than was previously the case, and it therefore when distended pushes up against the heart, which, degenerated as it is, can but ill cope with any more difficulties than it already constantly has to

surmount. The whole result is that the heart's action becomes tumultuous, irregular, or imperfect, according to the degree of degeneration which is present in its walls, and the patient experiences a feeling of distress which may proceed no farther or which may lead to so-called lipo-cardiac asthma, or syncope, or to epileptiform or apoplectiform attacks, any one of which may be more or less suddenly fatal. In cases where the heart muscle, though degenerating, is still able, for at any rate a short time, to respond to the increased excitation, the beats become very forcible and laboured, whilst the intravascular tension is raised and the return of the blood to the heart is interfered with. Under such circumstances there may be increased intracranial pressure, and epileptiform or even apoplectiform attacks with more or less profound unconsciousness may occur. In the latter case the breathing may become stertorous and the whole appearance may be strongly suggestive of cerebral hæmorrhage, but if the patient survives a few hours will generally suffice to show the true character of the seizure, for as a rule the attack is of but short duration and there are either no localising symptoms or if there be any muscular weakness it very soon passes off.

As regards treatment, if the disease be in an early stage cure may probably be effected by the absorption of fat and the hypertrophy of the muscle cells, but if the condition be more advanced the treatment presents much difficulty, for whilst almost every case needs its own special line of treatment it is frequently by no means easy to determine what will be beneficial in any individual case. The first requirement always seems to me to be, that the stomach should be treated by strict dieting as well as by gastric antiseptics, such as sulpho-carbolate of soda, creasote in mixture, or salicylate of bismuth, or if necessary by lavage. Further, it should be insisted on that the meals should be taken practically dry, the necessary quantity of fluid being drunk when the stomach is empty. In addition, some saline aperient such as Hunyadi Janos or Apenta water should be taken with a glass of hot water before breakfast. Later artificial digestants, mineral acids, gentian, strychnine, capsicum, &c., are of service, but it always seems to me that the first need is to clear the stomach and to attempt by preventing distension to reduce its size. As regards the heart itself, the most important thing is to diminish its work, and this may often be accomplished by making the patient rest in bed with a restricted diet, and by the regular exhibition of trinitrin or in rare cases erythrol tetranitrate. The milder cases do not, I think, need to be kept in bed if they can be trusted to move about slowly and to obey directions as to diet. Where the attacks are epileptiform or apoplectiform in character a more marked lowering of blood-pressure by diuretics and free purgation by salines and even sometimes by venesection is advisable. Alcohol, except for sudden emergencies, is, I think, better withheld, or if it be allowed it should only be taken in small quantities with meals. As regards the direct stimulation of the heart I have had, I think, the best results with sparteine sulphate combined with citrate of caffeine. In cases where the heart is rapidly failing beneficial results may sometimes be induced by administering full doses of strophanthus every hour for from 12 to 24 hours and by the inhalation of oxygen over the same period; but unfortunately in most of these cases where once the left ventricle has dilated to any considerable extent it is a sign that the unequal contest will soon be given up for good. When the seizure is over, however, the most important part of the systematic treatment must undoubtedly be directed to the stomach if future attacks are to be prevented. In most, or at any rate in a large number of cases, when they come under observation the stomach is found to be markedly dilated, and without question the onset of an attack, whether simply of distress, of dyspnœa, or of a more serious nature, is in the large majority of cases associated with flatulent distension of that organ.

"Hill heart," as this condition may be named, differs from fatty degeneration of the heart as generally described in that there is in the "hill heart" antecedent hypertrophy and consequently a greater liability to the apoplectiform and epileptiform kind of attack, both being associated with a temporary increase in the blood-pressure. The resulting high tension is thus due to a conservative constriction of the peripheral arteries and a resulting more forcible action of the heart when its movements are interfered with by a distended stomach or other cause. This, of course, to a considerable extent modifies the treatment and necessitates a variation in the methods to be employed according to the stage to which the disease has advanced.

With regard to the reflexly excited tumultuous movements it must be remembered that Gaskell, Morison, and others have shown that, contrary to what used to be taught, the whole of the heart substance is abundantly supplied with nerves. Further, as Morison has suggested, it is not improbable that simple hypertrophy with consequent stretching of the intermuscular nerves may, when only slight extra work is thrown upon the heart, cause slight increase of the tension on the nerves sufficient in itself to cause excitation of them, and so the origination of irregular contractions of the muscle, and thus the production of anginal pain.

I have only attempted to deal in some detail with fatty degeneration of the heart, with special reference to degeneration following hypertrophy but without valvular lesion. With such difficult subjects as the treatment of mitral stenosis, of uncomplicated aortic disease, of the sleeplessness of both aortic and mitral disease, and of the vomiting of mitral and tricuspid disease, I have made no attempt to contend, for each one would need a separate paper of its own if justice were to be done to it. Nor have I discussed the value of opium, of iodide, of arsenic, and of mercury in certain heart states, the heart conditions associated with septic disease, the toxic effects of alcohol and tobacco, syphilis, or the fatty degenerations resulting from too large or too long-continued doses of such drugs as phosphorus and arsenic. Finally, if I have perhaps insisted too much upon the danger of overloading the stomach when the heart is diseased I have only copied Shakespeare, who truly realised the importance of the matter when he made Macbeth say to the doctor who was treating Lady Macbeth:—

> "Cure her of that;
> Canst thou not minister to a mind diseased,
> Pluck from the memory a rooted sorrow,
> Raze out the written troubles of the brain,
> And with some sweet oblivious antidote
> Cleanse the stuff'd bosom of that perilous stuff
> Which weighs upon the heart?"

Bradford.

## TRACHEOTOMY WITH ANTITOXIN IN LARYNGEAL DIPHTHERIA.

BY W. BLAIR BELL, M.B. LOND., M.R.C.S. ENG.

IN spite of all the personal evidence and in spite of statistics there is still a lurking suspicion in the minds of some medical men and an absolute assuredness on the part of the laity who are of the anti-vivisection persuasion that the antitoxin serum has not fulfilled expectations. Those medical men who are still in doubt must have used it injudiciously—that is, too late or in too small doses, or only in the severest cases, or possibly not at all. Those of the laity who are waging a wordy war against its efficacy cannot have had the opportunity of being grateful to it for its curative action on themselves or those near and dear to them. I have used it continuously in all cases for the last four years and in my limited experience in my own practice I can say that I have not lost a single case directly from the disease. One patient died suddenly from heart failure associated with pneumonia nine weeks after tracheotomy had been performed, but beyond the cardiac weakness following the diphtheria one could hardly attribute the result to that disease. I had also to be personally thankful to it during a recent attack of diphtheria. It is not my intention to dilate on the use of the antitoxin beyond stating that the ordinary dose of 1500 units is quite inadequate for severe cases; and I now never give less than 3000 units for an initial dose, and do not hesitate at 8000 units for any patient over 12 years of age.

The following are notes of three consecutive cases of severe laryngeal diphtheria in which I performed tracheotomy last year. They were the only cases which required the operation, for others which I had during that period yielded to the antitoxin alone. I am convinced that the success attending the operations was due to the antitoxin given. A few years ago they would all probably have proved fatal. It would seem that the antitoxin loosens the existing membrane and prevents fresh membrane from forming, and

so in the severe cases tracheotomy will tide over the urgent dyspnœa while this is taking place.

CASE 1.—A fine fat infant, a boy, aged 16 months, was seen first on the afternoon of Feb. 20th, 1899. It was stated by his mother that he had had a sore-throat since the 14th and that he had begun to have a croupy cough on the 16th. The child was very blue, his pulse was 116 and feeble, and his respirations were 40 and very difficult. There were noisy râles all over the chest. The temperature was 97·4°F. The soft palate and tonsils were slightly congested, but there was no definite membrane to be seen (a swab taken at the time giving a negative result as regards the bacillus diphtheriæ). The glands in the neck were not much enlarged. A diagnosis of laryngeal diphtheria was made and, as the dyspnœa was obviously getting worse and the sucking-in of the supra-clavicular fossæ, intercostal spaces, and epigastrium was great, immediate tracheotomy was decided upon before the child should get worse, which seemed well-nigh impossible. 3000 units of antitoxin were injected and the operation was carried out, the child being anæsthetised with a small quantity of chloroform. Much membrane was obtained from the trachea and it seemed to have spread down to the bifurcation; this membrane subsequently gave a positive result when examined bacteriologically. A small silver tube was inserted. At the completion of the operation artificial respiration had to be performed for some time and three minims of ether were injected with one-sixtieth of a grain of strychnine before the child could be resuscitated. The patient's temperature rose during the night to 101°. At 10 P.M. 2000 more units of antitoxin were injected. Next day the child was very ill and restless with plentiful signs of broncho-pneumonia, and his temperature kept high. At 6.30 P.M. he had 1000 more units of antitoxin, and again the next day at 4 P.M. 1500 units more. The pneumonia gradually subsided and the child continued to improve steadily. On the 24th the silver tube was replaced by a soft rubber one, with which he was more comfortable. By March 2nd nothing but a little mucus was coughed through the tube. He had had a slight antitoxin rash and albuminuria, both of which had gone by this date. The child was so nervous that it was impossible to remove the tube permanently until the fifty-seventh day. Two days later he had an attack of lobar pneumonia in the upper lobe of the right lung with a rapid rise of temperature and he died suddenly the next day from cardiac failure. At the necropsy the larynx and trachea were found to be quite clear and the tracheotomy wound in the trachea was sealed up. The whole of the upper lobe of the right lung was engorged, and the heart was pale, flabby, and dilated.

CASE 2.—A well-nourished boy, aged four and a half years, was first seen at 2.15 P.M. on August 28th, 1899. He was lying very still. His respiration was 32 and difficult, he had a croupy cough, and in his chest were a few scattered râles; his temperature was 99° F. His mother said that he had had a sore-throat since the 25th and "croup" since the following day. 5000 units of antitoxin were injected as soon as possible. A swab was taken from his throat, which was very foul with much membrane, and this gave a positive result. In spite of the injection he got worse, so at 6.45 P.M. another injection of 3000 units was given. He still continued to go from bad to worse, his breathing getting very difficult and his colour blue, and there was great sucking-in above and below the thorax and in the intercostal spaces. At 10.45 P.M., therefore, tracheotomy was performed and a silver tube was inserted. Very little membrane was obtained from the larynx or the trachea. He passed a good night and his pulse-rate decreased, but his respirations stood at 36. He had slight albuminuria. I ordered one-sixtieth of a grain of strychnine to be injected daily. On the next day he seemed comfortable, but there was very little discharge through the tube, so he was given another 1500 units. Later he seemed very collapsed and he vomited a great deal, but got rid of much membrane through the tube and mouth. From this time he rapidly improved. The silver tube was replaced by a rubber one on Sept. 4th. On the 6th there was no albuminuria and the tube was permanently removed on the 11th. On the 25th the child was quite well and the wound was sound. He still remains in excellent health.

CASE 3.—On Nov. 17th, 1899, at 10 P.M., I was called in, in consultation with Mr. H. W. Lloyd, to see a boy, aged four years who, the mother said, had had a sore-throat for eight days and a croupy cough for six days. Mr. Lloyd had seen the patient for the first time two days previously and the swab he had then taken from the throat gave a positive result as regarded diphtheria, and consequently on the morning of the 17th he had injected 500 units of antitoxin. When I saw him the child had great difficulty in respiration, but as his general condition, colour, pulse, &c., were good, and as there was no marked sucking-in of the chest spaces I did not consider that tracheotomy was immediately called for, especially as he had had practically no antitoxin—for I do not consider 500 units of any use. Mr. Lloyd, therefore, at my suggestion, gave him 4000 units that night. I saw the child again on the next morning at 11.15 with Mr. Lloyd, when we found him much worse, his colour being dusky and the sucking-in of the thoracic spaces very marked. His pulse was 120, his respiration was 36, and there were râles all over his chest; he was very excited and restless. In the firm belief that one should always have a "bit in hand" as regards the condition of the patient in these cases and not leave tracheotomy to be used as a last resort, and as the child was getting worse and more rapidly so in the last hour or two, we decided that this operation should be done at once. Mr. Lloyd administered chloroform and I performed the operation with no difficulty beyond some extensive venous hæmorrhage from the very much engorged veins. At 12.15 P.M. the patient had another injection of 4000 units and again at 7.30 P.M. he had a further injection of 2000 units. I saw him on the two following days when he was rapidly recovering. He had an injection of one-sixtieth of a grain of strychnine daily. This I always think excellent as a cardiac stimulant. I did not see the child again as I contracted diphtheria myself from the case which developed four days after the operation, but Mr. Lloyd tells me that he removed the tube on the eleventh day and that the child made an uneventful recovery and is now well.

Since the danger of contracting diphtheria is mainly from the way in which the membrane is shot through the tube on to the operator when the tube is put in for the first time or when it is being cleaned daily, I have had made for me a small screen consisting of a circular glass plate (of the best thin plate-glass) which is one foot in diameter; this is fitted on to a Y-shaped handle of ebony and fixed by two pins which perforate the prongs of the Y, in which are slits for the glass plate, and holes bored in the glass. This allows the screen to be taken to pieces and cleaned. It is light and can easily be held by a nurse or assistant between the face of the person who is inserting the tube and the child's neck. It is only required at the moment of insertion.

Wallasey.

## A NOTE ON THE PATHOLOGY AND TREATMENT OF GASTRIC ULCER.

BY WILLIAM STUART-LOW, F.R.C.S. ENG.

THERE are few affections around which medical and surgical controversy has more strenuously striven than that of the pathology and treatment of gastric ulcer and with less profit either to the suffering patient or the puzzled and perplexed practitioner. Here pathology has failed to point the way to a proper treatment and therefore the therapeutics of gastric ulcer is still so much groping in the dark. A series of theories have been propounded, but each in its turn has failed to explain the malady or to serve as a foundation of a successful therapy. The clean, red, and sometimes angry or dry tongue, the clear, hyper-acid, non-mucous, and scanty vomit, and the constant constipation with the frequently dry scybalous stools certainly point to deficient secretion of the normal juices of the alimentary canal, but more especially to a deficiency of the mucous secretion—the natural protector and lubricator of the entire passage. Noting these and other features in the semeiology and the fact that many of my cases of gastric ulcer have been in patients suffering from the accompanying diseases of atrophic pharyngitis and rhinitis and amenorrhœa—conditions in which the pathology is admittedly clear and the dominating feature is that of a deficiency of mucous secretion—I have for some time been treating my cases of irritable stomach, painful digestion, and gastric ulcer with mucin with most satisfactory and gratifying results. I have had prepared for me through the offices of Messrs. Burroughs and Wellcome the mucin in powder form; they manufacture it from animal bile which contains it in large amount. It is

dark brown powder and almost tasteless and odourless and is therefore quite unobjectionable to swallow. This I give just before meals or rather as *hors d'œuvre* at the beginning of the meal in cachet form with an equal quantity (10 grains) of bicarbonate of soda. The good effects of this are markedly evident in the immediate alleviation of all painful sensations in the gastric region and in the establishment of regularity in the action of the bowels. That the constipation is relieved is a most important fact, and the value of mucin as an aperient is a great point in its favour as a therapeutic agent and of much interest physiologically. The diet of the patient is also carefully regulated and certain substances having a specially soothing and protecting action, such as animal jellies, calf's foot, mutton, and chicken jelly and thin cornflour, and the frequent use of a jujube of freshly prepared marsh-mallow, are allowed. I direct the feeding to take place every two or three hours, according to the severity of the symptoms. The *rationale* of this method of treatment is to protect the irritable gastric surface, and especially the ulcerated part, from attrition by the food and constant worry by the hyper-acid gastric juice—therefore the mucin is given first to form a gluey coating over the lining membrane, a kind of Unna's dressing is applied, and the surface is thus soothed and protected. If there is still any pain or uneasiness after nourishment then another cachet is given and thus the increased acidity is counteracted. The ulcerated surface on the stomach wall is treated just as an ulcerated surface on the body would be—it is protected from friction and by rest given a chance to heal.

Mucin is a compound substance, being composed of a proteid and a carbohydrate called "animal gum"; it is the principal constituent of mucus and is very widely distributed in the body, occurring in epithelial cells, goblet cells, and mucous glands. There are probably several mucins and they are all viscid and tenacious and precipitated by acetic acid and are dissolved by dilute alkalies. The contents of one cachet—10 grains each of mucin and bicarbonate of soda mixed in a glass with a little water and gradually heated to the temperature of the body—readily change into a sticky glue and this is the viscid solution that effectually protects the ulcer and the sensitive and inflamed gastric wall and regulates the bowels. The functions of mucin in the animal economy may be various, but one most certainly is that of the protection of the delicate membrane it pours over, not only from influences from without, but from the effects of other secretions as seen in the urinary and alimentary mucous tracts. We know that any injury to the healthy gastric mucous lining heals with marvellous ease and quickness because the wounded part is protected by the mucous present in the healthy state from the irritating influence of the gastric juice. And we also know that the gastric ulcers that bleed, as evidenced by melæna and hæmatemesis, are those that do not perforate but generally get well, as the effused blood no doubt takes the place of the deficient mucus and thus shields the ulcerated part and allows it time to heal over effectually.

Welbeck-street, W.

# A CASE OF DIFFUSE SUPPURATIVE PERITONITIS FROM GANGRENE OF THE APPENDIX; LAPAROTOMY; RECOVERY;

## WITH NOTES ON THE FREQUENCY AND MORTALITY OF PERITONITIS.

BY HENRY A. DUFFETT, F.R.C.S. ENG.

THAT disease of the vermiform appendix might be the cause of suppurative peritonitis was first recognised in 1827 by Louyer and Villermay,[1] but it was not till 1885 that Kronlein[2] performed the first successful median laparotomy for what was probably appendicular peritonitis. For though the perforation in the appendix was not itself found, fœtid and fæcal pus was found coming "mostly from the right side." This was followed in 1888 by two successful cases by Sands[3] and McMurty[4] by lateral laparotomy. Since then with modern methods of treatment, and recognition of the fact that laparotomy holds out the only hope for an otherwise hopeless condition, a considerable number of recoveries after operation have been recorded, though the mortality is still a terribly high one. In the causation of suppurative peritonitis the appendix holds a prominent place. Out of 47 cases due to all causes reported by Treves[5] 22 were appendicular in origin. The frequency of peritonitis occurring from disease of the appendix is estimated by Halliday[6] and Ryerson Fowler[7] at 14 per cent., and by Talamon[8] and Armstrong[9] at 8 per cent. It may occur either in the primary attack or in relapsing cases, and Fitz,[10] who has collected 256 cases of appendicular peritonitis, states that 11 per cent. of these occurred in course of recurrent attacks. Kraft[11] puts the frequency still higher at 25 per cent.

In a considerable number of cases (probably 25 per cent.) appendicitis is complicated by the formation of an abscess, and its rupture, flooding as it does the general peritoneal cavity with intensely infective material, is the most dangerous and fatal complication that can occur. In 30 cases of abscess reported by With[12] six burst into the general peritoneal cavity. Bull[13] has collected 67 cases in eight of which peritonitis was caused by rupture. The estimation of the mortality of "general suppurative peritonitis" is of considerable difficulty in consequence of the vagueness of the term "general" used in this connexion. Many of the cases reported are not so in reality, as Deanesley[14] has pointed out, but are merely large intra-peritoneal abscesses, and he thinks that the term cannot be fairly used unless (1) the pus extends as high as the umbilicus; unless (2) it occupies both flanks; and unless (3) it is limited by no firm adhesions. Barling[15] goes still further in thinking that the term should be restricted to those cases in which the subphrenic spaces are involved, as the pus is often limited by the transverse colon. If, however, we take it in its widest sense and include those cases of even limited intra-peritoneal suppuration apart from localised abscess, the mortality is still very high. Armstrong, Demoulin,[16] and MacDougal[17] estimate it at 60 per cent., Chauncy Puzey[18] and Hawkins[19] at from 75 to 80 per cent., whilst Barling[20] in his latest series of cases had the far better results of 35 cases and 21 recoveries, an average mortality of but 40 per cent. From the journals of the last five years I have collected 103 cases of general suppurative peritonitis in England treated by laparotomy with a mortality of 48 per cent. There can be no doubt that the early recognition of the presence of peritonitis is of the greatest importance. Every day's delay decreases the slender chances of recovery. Fitz out of 176 fatal cases found that death occurred in 56 per cent. in the first week and in 34 per cent. in the second, though probably the larger number of these and all that survived longer were but cases of intra-peritoneal suppuration well shut off. Of those that died in the first week 34 per cent. died within the first five days, and to save some of these it would have been necessary to operate within the first two or three days; but the difficulty of positive diagnosis and the hope that the peritonitis may become limited by adhesions will far too often prove an obstacle to early operation. The following case that has recently been under my care in the Seamen's Hospital, Greenwich, during the temporary absence of Mr. W. Johnson Smith, is of interest from the widespread distribution of the infection and the recuperative power that is so prominent in children. The history of the case is as follows.

A lad, aged 14 years, a boy at the Royal Naval School, Greenwich, was admitted to the Seamen's Hospital

[20] Loc. cit.

on Oct. 2nd, 1899, for acute pain and distension of the abdomen. Up to this time he had been a robust and healthy boy and his previous history disclosed no features of interest. He had had no attacks of pain at all resembling appendicitis and no attacks of colic or diarrhœa. For two or three days previously to the acute onset of the disease he had been feeling out of sorts but with no definite pain. On Sept. 29th he was lying on one of the seats in the playground and some of his companions in play sat upon his abdomen. He was at once attacked with acute pain in the abdomen, chiefly, according to his description, about the umbilicus, and was taken to the sick ward in connexion with the school. On the following day, the 30th, he vomited frequently and could retain neither milk nor other food. The bowels were confined. The pain continued severe but with exacerbations. On Oct. 1st the vomiting still continued, the bowels were confined, and he was given castor oil which was at once rejected. Subsequently an enema was given, but with a negative result. During the day it was first noticed that the lower part of the abdomen was rigid and did not move on respiration. I saw him first on Oct. 2nd with Mr. G. W. Armstrong and with his consent he was removed with all care to the Seamen's Hospital. On admission at 1 P.M. he was somewhat collapsed but soon rallied. His face was pale and drawn and the conjunctiva were slightly icteric. The temperature was 104° F., the pulse was 130, weak and compressible, and the respirations were 30. He complained of great abdominal pain, but largely localised to the left iliac fossa. There was extreme tenderness all over the abdomen, which was rigid in its lower part. The tenderness was specially marked on the left side. Both legs were drawn up and any attempt to straighten them much increased the pain. There was no abdominal distension and no swelling or tumefaction. The lower half of the abdomen did not move on respiration. He was ordered frequent hot fomentations and peptonised milk in small quantities. The milk, however, was at once returned and the vomiting then continued at frequent intervals. The vomit was bilious in character and by no means feculent in odour. An enema was given but without result, but on repetition brought away some scybala and then nutrient enemata were given every four hours. During the night he slept at intervals, but was often awakened by the pain. He vomited at 2 A.M. and again at 6 A.M. when the vomit had a distinctly feculent odour. On the morning of the 3rd he was obviously much worse. The temperature was 101° and the pulse was 120, weak and running. The abdomen was distended and hard and rigid. Palpation showed extreme abdominal tenderness specially acute in the left iliac fossa, the patient flinching at the slightest touch. The right iliac fossa was not more tender than the rest of the abdomen. There was absolutely no abdominal movement on respiration. As there was no doubt that general peritonitis was present, though the exact cause was doubtful, I decided to open the abdomen. From 8 A.M. the vomiting had been most persistent, and about 10 A.M. became stercoraceous. He was also troubled with frequent hiccough.

All precautions against shock having been taken and Dr. R. W. Mayston having given chloroform I opened the abdomen in the middle line by a four-inch incision below the umbilicus. On incising the peritoneum about half a pint of most foul and fœtid pus at once escaped. I increased the incision slightly upwards, and on introducing my hand found no adhesions in any direction. The intestines were lying free and bathed in pus which extended over the whole abdominal cavity, above the transverse colon as high as the liver and behind the stomach. There was a large collection of pus in the pelvis. In the right iliac fossa there was, however, some matting of the parts, and from this mass pus could be seen coming from an aperture through which I could pass my finger. It seemed now certain that it was the appendix that was at fault. I thoroughly flushed out the abdominal cavity with large quantities of boiled water, clearing it as much as possible from the pools of pus that were lying amongst the intestines and passing the nozzle of the irrigator well up to the liver and behind the stomach where the pus had collected somewhat abundantly, and washing out from above downwards so that the fluid should run as much as possible into the pelvis. As I found that it would be very difficult to reach the appendix through the median incision I placed a large flat sponge over it and made a second incision parallel to and above the outer half of Poupart's ligament on the right side, and on opening the peritoneum a further quantity of foul pus escaped. The appendix was now easily seen lying free in an abscess cavity, and on introducing my finger the opening leading into the peritoneal cavity was at once apparent. The appendix itself was gangrenous with a ragged opening at its extremity. No concretion was seen, but it might have escaped with the pus. After ligaturing its mesentery I tied off the appendix as close as possible to the cæcum by a single ligature. The abscess cavity was then flushed out and the abdomen was again thoroughly cleaned with boiled water which flowed freely out from the iliac incision. The excess of fluid was mopped up and a glass Keith's drainage-tube passed at the lower angle of the median wound into the pelvis. The remainder of the incision was closed in layers with gut sutures. The iliac incision was drained by a strip of gauze and the remainder of the incision was closed. Both wounds were dressed with cyanide gauze.

The patient stood the operation well. The fluid that had collected was drawn off every hour and in this way about an ounce was removed, and on the following morning, as no more had collected, the tube was removed. On Oct. 3rd he was given small quantities of peptonised milk. There had been no return of the vomiting. Both wounds were dressed and lightly packed with gauze. There was some discharge from the iliac wound which was feculent in odour. From this time to the 11th the patient made most satisfactory progress. He had no pain in the abdomen which was supple and moved freely. The bowels were well moved on the 4th, 7th, and 9th, and the temperature never reached above 99° or the pulse above 80. He was given milk, beef-tea, and cocoa, and on the 7th a small piece of thin bread-and-butter. On the 11th, however, his temperature rose to 101° and on the 12th and 13th to 102°. The abdomen became much distended and the abdominal wound which had entirely healed gaped. The iliac incision which had healed all but a small sinus also gaped, and the discharge which had hitherto been slight and odourless became exceedingly foul. The patient complained of acute pain in the abdomen and vomited immediately on taking nourishment. The pulse became rapid (110) and he passed a motion in the bed. The abdomen was acutely tender to the touch, and again this was specially marked in the left iliac fossa. On the 14th he was again obviously very ill, the temperature reaching 102° and the vomiting continuing. As a copious enema did not relieve him I thought that there was probably some recrudescence of the peritonitis, so he was again anæsthetised and the original median incision was reopened. Though numerous small adhesions were present there was no sign of pus or lymph, but some matting was now found in the left iliac fossa, which had all through the case been the site of the most acute tenderness. I thought, perhaps, that there might be some localised collection of pus in this situation, and fearing to reinfect the abdominal cavity I made a fresh incision on the left side identical in position with the one on the right. Adhesions were plentiful here also, but no pus was discovered. The median and left incisions were completely closed. The sinus in the right iliac fossa was explored and carefully enlarged and a small quantity of pus was found here. This was packed with gauze. This second operation also was well borne. The following day the temperature dropped to 99° and remained between this and 100° till the 20th when it reached the normal. The wound in the left iliac region healed by primary union, but the median incision again broke down, healing rapidly, however, by granulation. The sinus in the right iliac fossa closed gradually. The patient rapidly improved in strength, was out of bed on a couch on the 31st, and was sent to a convalescent home on Nov. 29th with all three wounds soundly healed.

What the exact origin of the peritonitis was in this case is doubtful, I think, but I believe that it was due to the sudden flooding of the peritoneal cavity with foul pus from the rupture of an appendicular abscess. If this is the correct explanation it is extraordinary that the abscess produced no symptoms previously to its rupture. Another solution of the case might be that the appendix had been inflamed for some time, for as Matterstock[21] states, the prodromal symptoms in children may last for a long time with but such slight inconvenience that a boy would take no notice of them. A somewhat similar case has been reported by Cushing[22] in

[21] Gerhard's Handbuch der Kinderkrankheiten, 1880.
[22] Boston Medical and Surgical Journal, No. 24, 1886.

which the appendix was ruptured in an apparently healthy boy by slight injury, fatal peritonitis resulting. If this was so in my case the abscess could be explained by the fact that the appendix was the origin of the mischief and that the more intense inflammation was going on in its vicinity.

The complete absence of special tenderness over the region of the appendix was most marked in my case, the pain being transferred to the opposite side. Fitz mentions this as occurring in but 1 per cent. of his collected cases. The mass in the right iliac fossa I did not discover before the operation on account of the extreme pain that any palpation produced, or by palpation under the anæsthetic as the abdomen was distended. I very much regret that I did not examine the patient per rectum which I am satisfied should be an invariable rule, but my only excuse is that he was so ill that I did not wish to put him to further pain. I cannot but mention the devoted care and attention that Mr. H. H. Cotman, the house surgeon, and the sister in charge of the case bestowed on the boy, and it was very largely due to their skill that a successful termination can be recorded.

Sidcup.

## THE REMOVAL OF SEPTIC EFFUSIONS FROM THE CAVITIES OF THE HUMAN BODY.

BY EDWARD ARMITAGE, M.R.C.S. ENG., L.R.C.P. LOND., D.P.H. CANTAB.

THE writing of the following article was suggested to me by the perusal of an abstract of a clinical lecture on the Joint Affections of Gonorrhœa delivered at the Leeds General Infirmary on July 17th, 1899, by Mr. B. G. A. Moynihan and published in THE LANCET of Nov. 18th (p. 1349). It was with great interest that I read the above article, but I must confess to a feeling of disappointment on finding that, as the lecturer observes, "so far as treatment is concerned there is little that is new to be said." I had hoped to see a description of the technique of incision of the joint, particularly since the successful results published by Dr. J. O'Conor, of the British Hospital, Buenos Ayres, in THE LANCET of July 8th, 1899 (p. 93). To us general practitioners who practise our profession in the outer corners of the earth,—

> "Islands of the Southern Run
> And cities of Cathaia,"

the subject of gonorrhœa and its complications is one of overwhelming interest, for it is one of the diseases which is most persistently forced upon our attention and possibly that disorder which we find most difficult to treat satisfactorily, and this for two main reasons: firstly, the indifference and almost criminal carelessness with which the disease is regarded by those who acquire it; and secondly, the difficulty or impossibility of persuading one's patients to observe that amount of rest and freedom from disturbing influences which is so necessary a factor in the treatment of the disease in its early stages as well as for the prevention of the fearful complications which so often prolong its course. Almost does one feel constrained to agree with that eminent surgeon who was inclined to consider gonorrhœa as a more appalling disorder than syphilis, and certainly I have often recalled to mind during the course of my practice the despairing serio-comic exclamation of the great Frenchman, Ricord: "Si je dois aller en enfer, je sais le supplice qui m'attend; c'est de me voir entouré de blennorrhéens m'obsédant de leurs lamentations, de leurs instances, de leur geste significatif pour obtenir guérison."

Any contribution, however modest, which may suggest an alleviation of gonorrhœal or other septic affections of the body-cavities may therefore be considered worthy of a hearing, which is my apology for the introduction of the following cases from my note-books. With respect to the treatment of gonorrhœa and its complications I have no doubt that my medical brethren will agree with me when I say that amidst the shower of new remedies with which we are overwhelmed in these latter days of the nineteenth century—remedies principally distinguished by their termination in one of the suffixes, "ine," "in," or "ol," as also by their costliness—we are occasionally obliged to hark back to first principles and to cure our patient with some time-honoured remedy; it is, in fact, with such a one (one of our most highly valued drugs—namely, mercury) that I am particularly concerned in this article. Now whilst I fully believe that the ideal treatment of these cases of gonorrhœal arthritis is incision of the joint under strictly aseptic precautions, removal if necessary of altered synovial membrane, irrigation with sterilised solutions, and closing of the joint under aseptic dressings without drainage—still I know that in the majority of cases this is a course of treatment which for various reasons we are unable to carry out and therefore we are compelled to treat our patients by medical measures.

CASE 1.—The patient, a young white man, came to see me from the island of Hawaii on Dec. 21st, 1897. He had been suffering from gonorrhœa followed by cystitis to which had succeeded infective arthritis of the metacarpo-phalangeal joint of one of his fingers. He had been treated, according to his own statement, by hypodermic injections of morphia, *usque ad nauseam*, and having been under my care during the early part of the year for another complaint had taken ship to come to consult me. The treatment which I employed was as follows: for the cystitis a mixture containing sulphate of magnesia and soda with tincture of belladonna, also hot sitz baths; and for the gonorrhœa emulsion of salol, five grains of the drug three times a day. The affected joint was painted with a liniment of green extract of belladonna and glycerine and covered with medicated wool. On Jan. 2nd an application of unguentum hydrargyri compositum was made to the affected joint which was compressed by strapping, and this application, together with warm bathing of the joints and massage, was continued until recovery ensued. During the same month he left the island of Maui permanently cured.

In connexion with the above case I should like to observe *en passant* that to judge from my personal observation there are still a considerable number of practitioners who have failed to appreciate the value of that golden maxim, which I believe we owe to the Birmingham School, "Opium masks symptoms." Since in 1891 it was particularly brought to my attention by an eminent teacher of that school in connexion with a case of "volvulus" it has always been impressed on my memory, and frequently, particularly in cases in which the peritoneum has been involved, have I had to recognise its extreme value.

CASE 2.—The patient, a young white man, came under my care from Honolulu on July 14th, 1898; he had been undergoing treatment for a considerable time. Here the infective arthritis involved the right knee-joint, which was much swollen and very painful. The treatment, as in the previous case, was by emulsion of salol (from five to seven and a half grains) internally every four hours. The patient was confined to his bed and the pain was relieved by sedative applications. Later in the course of his illness the joint was treated with applications of unguentum hydrargyri compositum and a tonic mixture of iron, arsenic, quinine, and citrate of potash was prescribed in addition to the salol. On August 27th he returned to Honolulu, the result being a permanent cure after a somewhat prolonged convalescence.

CASE 3.—This patient, also a white man, came under my treatment on Sept. 7th, 1899. He had according to his own statement been treated by hypodermic injections of morphine to relieve his pain which during the acute stages of the disease had been intense. The arthritis in this case affected the left wrist-joint and at the time when the patient first consulted me had assumed the chronic form; but, to judge from his statement, the disease whilst in the acute stage must have been of a very severe nature. The whole of the great synovial sac of the wrist-joint was filled with exudation, the contour of the joint was obscured, the surrounding tendon sheaths were enlarged, the hand was flail-like and painful on movement, the fingers could not be flexed on the palm, nor could movements of pronation or supination be performed without the aid of the other hand. No case could appear more suitable for incision and irrigation; in fact, I proposed the operation to the patient, but he preferred to wait and observe the effects of medicinal treatment, and being of a particularly active and robust physique he continued his work, which entailed a great deal of exercise on horse-back during the time he was under my care, with the exception of one or two days, when on my advice he had some defective teeth filled by a dentist in order to avoid buccal trouble during the mercurial treatment. Medicinally he was treated at various times with salicylate of sodium, salol, urotropine, and iodide of potassium. But the most marked effect was obtained by

the application of unguentum hydrargyri compositum spread on lint, enveloping the enlarged synovial bursa and tendon-sheaths, and surrounded by a strong compress of adhesive plaster. Occasionally the application was intermitted for a few days whilst the affected part was massaged, after which the tendon-sheaths were painted with tincture of iodine and the hand enveloped in cotton wool. By Dec. 20th the patient's hand, formerly in such a desperate condition, was almost entirely cured, the swelling of the tendon-sheaths in the neighbourhood of the joint was very slight, movements were freely performed, and although, owing to the length of time during which the hand had been confined, the muscles were somewhat atrophied it was a useful member.

I gave the above title to this paper in order that I might introduce a case of effusion into the cranial cavity of bacterial origin which was treated on somewhat similar lines as the cases already mentioned. On Oct. 24th, 1898, I was summoned to a sugar plantation, Spreckelsville, on the island of Maui, to see a sick child. The patient, a half-caste girl, aged about three years, proved to be suffering from bronchitis. The usual remedies were prescribed. Two or three days later further examination revealed consolidation of the apex of the left lung and the case assumed a more serious aspect. On Oct. 29th signs of basic meningitis appeared. Fortunately, owing to the kindness of neighbours, I was able at this time to have the child removed to more comfortable quarters, whilst satisfactory arrangements for nursing were made. The child presented the symptoms of acute meningitis: high fever, retraction of the head, hydrocephalic cry, and slight squinting; the tache cérébrale was not marked, however. During three days the patient was unconscious of her surroundings. The treatment adopted was the administration of an effervescing mixture, containing sulphate of quinine, bicarbonate of potash, and citric acid every two hours, according to the recommendation of Dr. I. Burney Yeo.[1] Cold applications were applied to the head, and, in addition, I ordered that one teaspoonful of mercurial ointment should be rubbed into the shaven scalp for a quarter of an hour each day. On Nov. 4th the child was convalescent and made an uninterrupted recovery.

In his "Practice of Medicine" (third edition, July, 1898, p. 956) Professor William Osler says: "There are no remedies which in any way control the course of acute meningitis"; he makes no reference to mercurial inunction. As to other applications, whether hot or cold, it seems to me unreasonable to suppose that they can exercise any influence whatever on a septic process which is taking place at so great a distance from the surface. But in the case of mercury we have a drug which admittedly penetrates the tissues underlying the skin, whilst in many morbid conditions its detergent power has long been a matter of common observation. That the cerebral disorder in the case just narrated was due to direct infection ascending by way of the blood- or lymph-paths from the diseased left apex appears to me to be an undeniable fact only requiring bacteriological evidence, unfortunately unattainable, for its final proof. Such being granted, surely it must be acknowledged that we have in mercury locally applied a most powerful agent against morbid processes of bacterial origin, and such being the case is it not surprising that it should not be more frequently employed?

I may add, in conclusion, that in the case of a Japanese suffering from "idiopathic" (?) meningitis and treated in a like manner in 1895 I had a similar happy result.

Wailuku, Island of Maui, Hawaiian Islands.

## NOTE ON A CASE OF ACUTE GLAUCOMA THE RESULT OF AN OPERATION FOR SECONDARY CATARACT.

BY CHARLES BELL TAYLOR, M.D., F.R.C.S.EDIN.,
SURGEON TO THE NOTTINGHAM AND MIDLAND EYE INFIRMARY.

THE patient came under my care in his eighty-sixth year, suffering from asthma, chronic bronchitis, and constant cough. He had been blind for some years from senile cataract in the right eye and latterly the left eye had become similarly affected. Operation had not been recommended by an ophthalmic surgeon who had been previously consulted on account of the patient's numerous infirmities, and there seemed to be little chance of ameliorating his condition. Nevertheless, as the patient was very anxious to see and as he could not well be worse off than he was, I determined to extract the cataract on the right eye.

The operation was performed under cocaine without misadventure and without iridectomy, and although the eyeball collapsed completely on extraction of the lens—assuming the form of a tiny bird's nest—the patient made a good recovery and there was no subsequent prolapse of the iris. 12 days later, as the pupil of the operated eye was central and freely dilatable, I ventured to divide a piece of the capsule with the needle-knife and he returned to his home in a northern county with every prospect of good vision. I was disappointed, however, when on a visit in his neighbourhood four months later to find that he could see very little and that the slit in the capsule had closed. I was consequently compelled to remove the peccant membrane *en masse*, which I did with iris forceps through a small incision in the corneo-sclerotic junction. All went well for three days, but on the night of the fourth I was sent for as he was suffering from intense pain which had not been mitigated by the instillation of atropine. The eyeball was as hard as stone and I therefore incised the sclerotic and punctured the hyaloid fossa, letting out a few drops of vitreous. Agony was at once changed to perfect ease. There was no further trouble, and although he has suffered severely from repeated bronchitic attacks he now has a good-looking eye with a central pupil and excellent sight.

It has seemed to me desirable to record this case not only on account of the success of simple extraction under most trying conditions, not only on account of the failure of discission of the capsule and the advent of acute glaucoma when that membrane was removed in its entirety, but also because of the instant arrest of the glaucomatous process by an operation which did not involve excision of the iris.

The occurrence of glaucoma, both in its simple and acute forms, though rare after operation for secondary cataract, is a contingency that has to be reckoned with and it is noteworthy that although its progress may be at once arrested by excision of the iris or puncture of the hyaloid fossa it is not inhibited or prevented by iridectomy, either as a preliminary or when performed as a part of the operation of extraction for cataract. One would think that if it were possible to cut open the eyeball and to remove so important a portion of its contents as the lens itself without misadventure or serious consequences that any subsequent dealing with a mere shred of capsule would be almost, if not quite, danger free. It is not so, however. Many surgeons consider that a second operation is as serious or even more serious than an extraction. Professor Nuel of Liège says that "a simple discission of capsule is quite as dangerous as an extraction for cataract"; Professor Gayet of Lyons says, "There is no operation I dread more"; Professor Kalt of Paris says, "Secondary cataracts always give me great anxiety"; and Dr. Valude (editor of the *Annales d'Oculistique*) says, "C'est la vraiment le gros avator de l'operation de la cataract, la vrai complication plus redoutable que les prolapsus iriens qui guerissent bien et que la panopthalmie si rare." Trosseau, Eperon, Bribosa, and Critchett warn us against the disastrous consequences that occasionally follow operations for secondary cataract and, although my experience of some thousands of cases of extraction of cataract has on the whole been favourable, I have still seen quite enough to warrant me in insisting that we cannot be too careful when dealing with secondary membranous formations.

The late Alexander Pagenstecher and, more recently, Delgardo of Madrid, have sought to solve the problem by scooping out the lens capsule and all at the time of extraction, but this operation does not always attain the end in view and involves loss of vitreous, deep anæsthesia, and conspicuous deformation of the pupil. The late Professor Hansen used habitually to puncture the hyaloid fossa at the time of extraction in order to secure a clear pupil, a practice which I see has been recently revived by Mr. Work Dodd. Other surgeons, by cross-hatching the capsule (Swanzy), or by removing as large a portion as possible with forceps at the time of extraction, have sought to avoid the necessity for subsequent interference. These operations, however, are neither quite

[1] Manual of Medical Treatment and Clinical Therapeutics, vol. i., p. 563, fifth edition.

so safe nor so feasible as they seem to be and are apt to be followed by wrinkling of the capsule cell proliferation or more or less obscuration of the pupil. Besides, the breaking up of the capsule sets free particles of lenticular cortex which are not easily seen at the time of extraction and which although comparatively harmless when retained within the capsule become a formidable source of irritation if set free in the anterior chamber or when brought into contact with recently cut surfaces. It is best, therefore, I think, as a rule, to follow Professor Knapp's advice and to incise the capsule in its periphery only on a level with the upper border of the lens, to get rid of as much cortex as possible, and to take the chance of a second operation should that become necessary. If it does become necessary then we must above all be careful to avoid any manipulation that will involve drag on the ciliary processes. The late Sir W. Bowman endeavoured to avoid this risk by breaking up the capsule with two needles, one in either hand. With these he penetrated the cornea at an angle of 60° or thereabouts, pierced the capsule, and then, by revolving the points of the needles round each other and separating the handles, tore the opaque film asunder without any drag on the tissues with which the capsule is connected. The needles, however, are apt to dig into the vitreous humour, manipulation of the doubly impaled eyeball is difficult, and the operation is not always successful; hence Professor Noyes of New York has suggested that we should transfix the eyeball with a Graefe's knife, and then with two blunt hooks passed through each of the external wounds and pulling one hook against the other, establish a sufficient aperture without drag on the ciliary region. The hooks, however, can only be withdrawn with their concavities upwards, and the double manipulation of the eyeball on the stretch and with a contracted pupil complicates matters sometimes to an embarrassing degree. I have, therefore, substituted sharp hooks so curved that they may be entered and withdrawn in any position. These operations, however, do not always attain the end in view, and we are at present practically limited to a choice of three methods when operating for secondary cataract: (1) simple discission through the cornea as practised by Professor Knapp and myself within a fortnight of extraction; (2) simple discission behind the iris and through the sclera, three millimetres from the limbus, as advocated by Gama Pinto and at present practised by Harry D. Noyes of New York; and (3) avulsion of the membrane, as adopted in the case which I have here recorded—an operation which is habitually practised by Professor Panas of Paris and which may be rendered comparatively safe by first separating the circumferential attachments of the capsule.

Nottingham.

## A CASE OF MALIGNANT DISEASE OF THE OVARIES.

BY PERCY J. BAILY, M.B. EDIN.,
SENIOR ASSISTANT MEDICAL OFFICER, LONDON COUNTY ASYLUM, HANWELL;
AND
JOHN R. LORD, M.B. EDIN.,
ASSISTANT MEDICAL OFFICER, LONDON COUNTY ASYLUM, BEXLEY.

THE case here recorded is one of malignant disease of the ovaries which presents clinical and pathological features of considerable interest.

The patient, a single woman, was admitted into the London County Asylum, Hanwell, on Nov. 7th, 1897. At the time of her admission she was 56 years of age and was suffering from terminal dementia. She had been insane for over 17 years, was of German nationality, and was absolutely incoherent, and quite incapable of describing or complaining of any unusual sensation or symptom. Her bodily health was indifferent, but until October, 1898, this called for no particular note. Early in this month, however, she became obviously worse and was put to bed. On Nov. 3rd she was allowed to get up, but walked about with her body bent slightly forwards and with her hands placed over her abdomen as if in pain. She was therefore put back to bed and on examining her abdomen nothing abnormal was detected. The abdominal parietes were somewhat retracted but not more so than would have been expected from her partially emaciated condition. No vaginal examination was made at this time. She remained in bed and no further detailed examination was made until Nov. 17th, on which day she vomited. It was then found that there was a swelling occupying the lower part of the abdomen. It appeared to be rising out of the pelvis rather to the right of the middle line and extended to about halfway between the pubes and umbilicus. It was rounded in shape, fairly regular in outline, dull upon percussion, and firm but somewhat elastic to the touch. A catheter was passed upon which about an ounce of normal urine was withdrawn. Per vaginam it was found that the uterus was pushed over towards the left and against the posterior pelvic wall, the cervix being depressed and easily accessible. Her temperature on the evening of this day reached 99·6° F. and on the 18th at 8 P.M. it reached 100·6°, the highest recorded point. During the next few days her temperature generally rose to 100° at night, falling in the morning to 99°. On Nov. 27th she commenced to suffer from diarrhœa of a mild type. By this time the tumour had increased enormously in size, being, as far as one could judge, at least three times as large as when first observed on the 17th (10 days previously). Its character also had altered. It was no longer regular in outline but had become distinctly nodular and the percussion note over it was now not uniformly dull. Its highest limit had reached to above the level of the umbilicus, and about three inches to the right of the middle line the tumour was crossed in a nearly vertical direction by a line of resonance. This line of resonance ceased in the right iliac region about two inches above Poupart's ligament. On the left the tumour had now extended well towards the flank. The left upper corner of the growth was cut off from the remaining portion by a line of resonance almost semicircular in shape. With these two exceptions the whole of the tumour was dull on percussion and no evidence of the presence of any fluid could be made out. There was no ascites. The superficial abdominal veins were more evident than usual.

On Dec. 6th the patient was put under chloroform and an exploratory incision was made by Dr. M. Handfield-Jones. There were extensive adhesions and the tumour was found to be almost solid throughout. Death took place on the morning of Dec. 9th.

At the necropsy, which was held within 24 hours after death, a large tumour was revealed arising from the pelvis. The kidneys were quite free. Some coils of intestine were free in the upper part of the abdominal cavity, but the remainder were adherent to the tumour which to all appearances had infiltrated the mesentery. The tumour was in the middle line and was firmly adherent around the brim of the pelvis. It was slightly adherent to the posterior parietes, but had formed somewhat firmer adhesions with the lower part of the anterior abdominal wall. On removal it was found to be a growth from the region of the right broad ligament. The ovary on that side could not be found, but the Fallopian tube was intact. The tumour therefore in all probability grew from the right ovary. In doing so it pushed the uterus backwards and tilted it to the left side. It appeared to have infiltrated the sacral glands, making a firm union with the rectum and also the lumbar glands and the mesentery above. On its anterior surface were two coils of intestine which corresponded with the resonant areas found clinically. On the left it was adherent to the left ovary, which was also the seat of malignant disease and had become enlarged to the size of a small fist.

On section the central part of the tumour was white and had the appearance of loosely packed fibrous tissue. The peripheral parts had a red, fleshy appearance. These growths, together with the uterus, which was small and atrophic, weighed 3·63 kilogrammes (a little over 8 lb.). The larger tumour measured, taking its greatest diameters, 24 centimetres long by 18 centimetres broad and 14·5 centimetres thick.

Microscopical examination of the various parts of the tumour revealed a great diversity in the component elements. Some parts were composed almost entirely of cells, with an intercellular substance slightly fibrillar or granular; other parts were almost entirely composed of bundles of fine fibres, with here and there a small round cell; and other parts had a striking lymphatic structure. There were extensive hæmorrhages into the substance of the tumour generally, every field containing scattered blood corpuscles and many

of them altered in shape. The blood-vessels were for the most part not clearly defined, or were defined by rows of spindle-cells. A correct description of the cell elements of ovarian tumours is of extreme value from many considerations which cannot be entered into here. The normal structure contains many cells of a very elementary type, which makes it conceivable almost for any kind of tumour to be developed, and also renders it possible for great metaplasia to occur in any one growth. Some parts one could classify as being fibro-sarcomatous, others as small round-celled sarcoma, and others as lympho-sarcoma. Oval cells did occur, but were isolated and few in number.

The following were some of the commoner cell elements: (1) extremely small, darkly-stained, round cells, about two-thirds the size of a red blood corpuscle, which may have been nuclei of broken-down cells (?); (2) cells a little larger than a red blood corpuscle, staining poorly with a small nucleus or nucleolus; (3) still larger cells staining deeply and containing many granules; (4) cells similar to No. 3 but oval; (5) cells like large leucocytes with two or three nuclei present; (6) large flat cells, oval or irregular, sometimes containing a nucleus; (7) small branching cells; and (8) red blood corpuscles, some showing a degree of poikilocytosis (?).

*Remarks.*—Pathologically, malignant ovarian tumours are of interest because of the obscurity which surrounds the actual tissue from which they develop, particularly when they occur after the climacteric period. In the normal ovary the cell elements are mainly of two kinds: (*a*) the germ epithelium of Waldeyer with the various cells forming a Graafian follicle; and (*b*) connective tissue elements, condensed in the cortex but everywhere of an elementary type. The rapid growth and extensive infiltration in this case point to sarcoma. The age, however, is somewhat over the time at which the commoner forms of sarcomata commonly develop. According to Cohnheim, tumours grow from unutilised embryonic tissue, and it is extremely probable that in this case the growth took its origin in the elementary form of connective tissue mentioned. A malignant growth having its origin in the epithelial coverings of the ovary was possible. The age of the patient was one at which there is a proneness to malignant disease, and the most likely part of the ovary to take on this character was this elementary form of connective tissue. The growth was rapid, a little over two months being taken to produce a tumour of great size. A noticeable clinical feature was the absence of ascites, the presence of which is so usual in ovarian growths.

## PRUSSIC ACID IN SWEET CASSAVA.

BY PROFESSOR CARMODY, F.I.C., F.C.S.

FRANCIS, one of my predecessors in the Trinidad Government Laboratory, was the first[1] to point out that prussic acid was present in sweet cassava to a considerable extent. Francis's results have not received the attention which they deserved, probably because they were a direct but unconfirmed denial of statements repeatedly made by recognised authorities. There are very few recent editions of toxicological handbooks that make any reference to the results published by Francis. Even in standard reference works like that of Dr. Thorpe's "Dictionary of Applied Chemistry" it is stated that "the milky juice in the sweet variety is innocuous, whilst that in the bitter is highly poisonous."

The question is of importance from a toxicological point of view in those places in the tropics where cassava is used extensively as a food. For poisonous symptoms are not infrequently reported after a meal of sweet cassava; and as the two kinds of cassava—the sweet and the bitter—are so much alike as to be almost indistinguishable, the conclusion usually arrived at is that the bitter variety has been cooked in error.

My results fully confirm those of Francis as to the presence of hydrocyanic acid, although his average figures are somewhat higher than mine. This year has been an unusually dry one for Trinidad and a diminished supply of rain does affect the character of plant juices.

[1] Analyst, April, 1877.

The method of analysis adopted by me differs somewhat from that of Francis. He grated 500 grammes of cassava into 500 cubic centimetres of water which was left for two hours in a well-closed vessel. It was next strained through a linen cloth into a flask which was then corked and allowed to stand until the starch subsided. 200 cubic centimetres of the clear liquid were decanted and distilled and the results obtained were multiplied by four for the total in 500 grammes. This calculation was based on the assumption that the original 500 grammes contributed 300 cubic centimetres of water—an assumption which is not far from the truth if the cassava is quite fresh. Francis also remarks that a slight loss occurred during the process of grating, and in a tropical laboratory this loss might be appreciable. I endeavoured to avoid this loss on the one hand, and the possibility of error through assuming that all cassavas contained 60 per cent. of water on the other, by taking the whole root, slicing it quickly, and allowing it to stand in water all night in a well-corked flask. The liquid was decanted in the morning and the whole distilled. The extraction with water was repeated a second and a third time. The slices effectually prevented the great disadvantages arising from the starch finding its way into the distilling flask, which Francis prevented by subsidence but which necessitated his distilling an aliquot part, this aliquot part being a *definite* volume of 200 cubic centimetres taken from an *approximate* total volume of 800 cubic centimetres.

Francis does not appear to have made more than one extraction with water. I have made three in all cases and in some as many as five. I have found that with slices the second extraction yields as much, and sometimes more, than the first. I have repeated Francis's method of grating and find that a second extraction yields about half as much prussic acid as the first. It would appear from this, therefore, that Francis's results are not as high as they would have been had he made a second extraction. The figures obtained by Francis and myself are:—

| | HCN per cent. | |
|---|---|---|
| | Francis. | Carmody. |
| Mean ... ... ... ... ... | 0·0168 | 0·010 |
| Highest ... ... ... ... | 0·0238 | 0·019 |
| Lowest ... ... ... ... ... | 0·0113 | 0·005 |

It will be seen from this that while my "lowest" percentage is much below that of Francis my "highest" is nearly the same as his. This establishes the truth of the statement made by Francis, "that the so-called *sweet* or harmless cassava not only yielded prussic acid, but the quantity obtained from it so nearly equalled that from the *bitter* that no line of distinction could be drawn between them," so far as it relates to the amount of prussic acid in the cassava; but I have discovered an analytical difference between the two kinds by means of which they can be satisfactorily distinguished.

This discovery arose in trying to avoid the difficulties caused by the presence of starch in the distilling flask. At first I placed the slices in the distilling flask, added water in one set of experiments, and passed steam through in another and collected the distillates. This failed in each case through the gelatinising action of the boiling water or steam on the starch. This starch being chiefly confined to the inner portions, in my next experiments I soaked the inner slices in water at ordinary temperature, decanted and distilled. The quantity of starch thus admitted into the flask was so small as not to interfere with the distillation. The skin and outer cortical layer, which together constitute about one-fifth of the total weight of the sweet cassava, could be placed direct in the distilling flask, and the distillation carried on satisfactorily. It was this separation of the parts for convenience in distillation that led to the discovery that in sweet cassava the prussic acid is located chiefly in the skin and outer cortical layer.

The following are some of the results obtained from fairly representative samples of sweet cassava.

| Inner part. HCN per cent. | Skin and outer cortical layer. HCN per cent. | Inner part. HCN per cent. | Skin and outer cortical layer. HCN per cent. |
|---|---|---|---|
| 0·006 | 0·033 | 0·004 | 0·024 |
| 0·003 | 0·014 | 0·010 | 0·030 |
| 0·015 | 0·033 | 0·004 | 0·042 |
| 0·002 | 0·031 | 0·005 | 0·038 |
| 0·011 | 0·020 | 0·003 | 0·034 |
| 0·008 | 0·032 | | |

With bitter cassava the following results were obtained from representative samples :—

| Inner part. HCN. per cent. | Skin and outer cortical layer. HCN. per cent. | Inner part. HCN. per cent. | Skin and outer cortical layer. HCN. per cent. |
|---|---|---|---|
| 0·031 | 0·024 | 0·017 | 0·019 |
| 0·034 | 0·012* | 0·019 | 0·020 |
| 0·021 | 0·025 | 0·016 | 0·024 |
| 0·037 | 0·014* | 0·017 | 0·020 |
| 0·030 | 0·025 | 0·013 | 0·016 |
| 0·014 | 0·013 | 0·032 | 0·035 |

* Exceptional.

The general conclusions to be drawn from these results are: (1) that in sweet cassava the prussic acid is not uniformly distributed throughout the tuber and that in bitter cassava it is uniformly distributed, or nearly so; and (2) that this affords an analytical means of distinguishing between *sweet* and *bitter* cassava.

An important observation in connexion with local methods of eating cassava is that the skin of the sweet kind is removed before boiling, the inner portion alone being cooked and eaten. This custom is no doubt the result of experience and accords with what science would now teach as a wise precaution. But notwithstanding this removal of the skin ill-effects are said to follow from the use of the inner portion if water is drunk some time after a meal. This may now be accounted for in this way. It is shown in my experiments that whilst a first boiling removes a certain amount of hydrocyanic acid—all, in fact, that exists ready formed in the tuber—that a second addition of water and subsequent boiling removes a further portion. It would appear from this that cassava in a person's stomach would also develop an amount of prussic acid equivalent to that obtained in a second distillation and that the drinking of water would dissolve this and cause it to act more readily on the system. The total quantity would, however, be far below the minimum fatal dose and would only be expected to produce those unpleasant results occasionally reported. The question next arises—Is this second portion of hydrocyanic acid produced by fermentative changes, as is known to happen in the case of bitter almonds; or is it part of that originally existing in the tuber and in some way protected from the solvent action of the first treatment with boiling water? It is possible that, with slices, the water would penetrate slowly to their interior, and thus produce a second yield of prussic acid; and that if the cassava had been grated, as was done by Francis, the water would within Francis's limit, dissolve the whole of the acid. I have not found this to be the case, as the following experiment shows :—

*Sweet Cassava.*

It would appear from this and similar experiments that the whole of the hydrocyanic acid cannot be removed from grated cassava by a two hours' extraction with water and that there is apparently a loss of acid even when the grating is done under water. And, notwithstanding that my yield from slices is the higher of the two, Francis's results from a two hours' extraction are appreciably above mine. As already stated, this may be due to the exceptionally dry season. Next year I shall continue the experiments in order to clear up this difficulty. At present I am inclined to believe that part of the acid may be formed by fermentative change. If this be so cassava starch on keeping would be likely to be more poisonous than when freshly prepared. Fermentation beyond a certain limit entirely decomposes the hydrocyanic acid. Cassava is also cooked by roasting the entire tuber. This removes all the HCN.

There appear to be no grounds for the common belief that sweet cassava contains more HCN the older it is. In all the samples examined during a period of nine months from the time cassava was first brought to market the proportion of HCN showed no increase that could be traced to age. Nor is there any ground for the belief that the locally grown sweet cassava is but a degenerate growth resulting from many years' association with the bitter variety. A selected sample imported from Jamaica and grown at the Local Government gardens contained the same amount, and the same relative proportions in skin and inner part, of HCN as the ordinary product of Trinidad.

The subject is not yet exhausted, and I hope to be in a position to publish further results next year.

Trinidad.

**Nulla autem est alia pro certo noscendi via, nisi quamplurimas morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.**

## YORK COUNTY HOSPITAL.

### FOUR SURGICAL CASES.

(Under the care of Mr. W. H. JALLAND.)

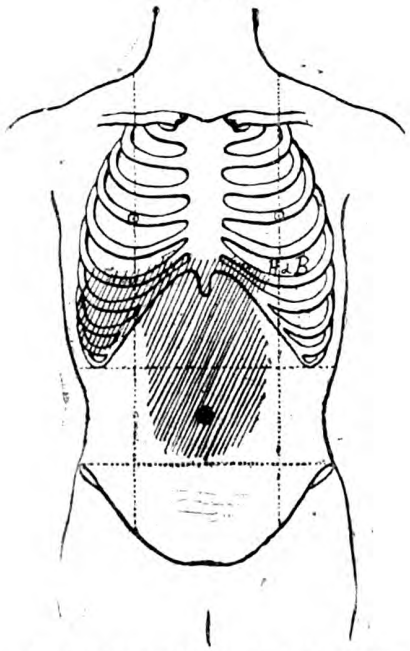
THE first of the following series of cases is an illustration of the occasional beneficial effects of an operation, even though no lesion is discovered. This result is probably most frequently seen in operations for suspected renal calculi, when although no stone can be found relief of all the symptoms follows. Various explanations have been offered, that some slight adhesion has been broken down, that some local congestion has been relieved, that some nerve has been divided, and lastly, that the result is entirely the effect of the operation on the patient's mind. Whichever explanation may be true—and probably each is true in some cases—there can be no doubt as to the reality of the improvement which follows. The third case shows the benefit of early operation in intussusception, especially in very young children.

CASE 1. *Exploratory laparotomy for severe abdominal pain; no disease detected; recovery.*—A married woman, aged 39 years, was admitted into the York County Hospital on August 3rd, 1898, under the care of Mr. W. H. Jalland. For some time previously to her admission she had been suffering from severe gastric pain which it was thought might possibly be due to passing gall-stones, though this was doubtful. She never was jaundiced. She had violent sickness and the pain was so severe that she had had frequent injections of morphia. On admission she was somewhat wasted in appearance, with an anxious expression, and was evidently suffering at times considerable pain, although the region of the pain was somewhat indefinite, being described as above the abdomen. Her weight on admission was 5 st. 7 lb. She was put upon small quantities of peptonised milk and beef-tea, with drachm doses of bromidia when the pain was very severe. As she was not much better on the 26th the stomach was washed out and this was repeated on the 29th. As she was somewhat relieved after this food was gradually increased. There was no necessity to give her any more sedative. She had been kept in bed previously to this, but got up on Sept. 15th and left the hospital considerably relieved on the 24th. She was admitted again on Feb. 16th, 1899, all her symptoms having returned. The same plan of treatment was adopted; the stomach was washed out frequently, small quantities of food gradually increased were given, and she left the hospital much relieved on March 23rd. She was admitted again on July 13th, 1899, the symptoms having returned in a much aggravated form. She

had wasted very considerably and really looked very seriously ill. She begged that some operation might be performed to relieve her pain and trouble; so, at the woman's urgent request, it was decided to perform an exploratory laparotomy which was accordingly done on July 18th under ether. The incision was made in the median line in the usual way above the umbilicus. The stomach was first examined and nothing wrong with it could be detected. It was brought out of the incision and examined thoroughly all over. There were no adhesions nor was there any thickening of the pylorus. The gall-bladder was next examined and found to be perfectly healthy in every way, nor was there anything to be detected in the cystic or common duct. Under these circumstances it was thought advisable to examine no further but to close the wound. After the operation the patient expressed herself as feeling most comfortable. Her temperature never rose above 99° F., and reached that height on only two occasions. The wound was dressed and the stitches were removed on July 26th and she went out of the hospital perfectly well on August 14th. Since then she has been almost entirely free from pain and has increased in weight over a stone. The patient was seen on Oct. 26th and was then perfectly well and had put on 3½ st. in weight.

CASE 2. *Large cyst in the liver (? hydatid or simple cyst); laparotomy; drainage of the cyst; recovery.*—A married woman, aged 28 years, was admitted into the York County Hospital on Sept. 7th, 1899, under the care of Mr. Jalland. She had had three children, the youngest being seven years old. She had had no miscarriages, nor was there any specific history, and her confinements had all been normal. She had had some ulceration of the palate in 1896 and she had on admission some necrosis of bone and a discharge of the sinus in the left lacrymal duct region which preceded the ulceration of the palate. In September, 1898, she had complained of great pain in the left lumbar region and was in bed for about five weeks, during which time she lost weight and flesh. She had first noticed that her abdomen was enlarging about May, 1899. The abdomen had greatly enlarged since, especially during the previous two months. On admission she was found to have a large fluctuating swelling in the upper part of the abdomen in the median line, extending from the upper ribs to some two or three inches below the umbilicus, which was apparently connected with the liver (Fig. 1). It was not tender on pressure, but

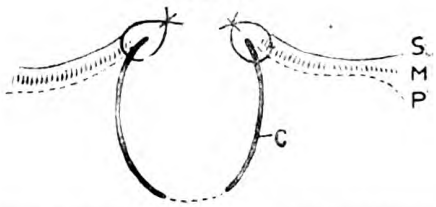
FIG. 1.



The shaded portion shows the extent of the cyst.

was elastic to touch and evidently contained fluid. She had noticed this now for over a year and it was gradually increasing in size. She had not menstruated for a year and she had some impression that the swelling had grown since menstruation had stopped. The girth of the abdomen at the umbilicus was 35½ inches; the largest girth, one and a half inches below the umbilicus, was 36¼ inches. On Sept. 19th, under ether, a free incision was made in the median line over the tumour from the umbilicus to within half an inch of the ensiform cartilage. The abdominal cavity was opened in the usual manner, and a bluish-black tumour presented itself in the wound. On investigation it was found to be firmly adherent to the transverse colon by well-organised fleshy adhesions and also above to the liver. The cyst was tapped with a dagger trocar and the contents, which were of a brownish-black liquid character, were evacuated. Further investigation showed the tumour to proceed from the right lobe of the liver, and the adhesions to the colon were of too firm a character to be separated, so it was decided to drain the cyst thoroughly and to suture it to the opening in the abdominal wall. The opening in the cyst made by the trocar had been closed with a large clamp forceps. The edges of the opening of the cyst were now carefully sutured to the peritoneal surface, as explained in Fig. 2, and a large number of silk sutures were placed

FIG. 2.



C, cyst wall adapted to P, peritoneum; M, muscular abdominal wall; S, skin.

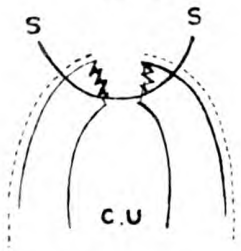
evenly at intervals of one and a quarter inches round the opening. When the cyst cavity had thus been completely shut off from the peritoneal cavity the silkworm-gut sutures were passed through the skin and muscle at the upper and lower ends of the wound, so as to reduce the size of the external opening, and, finally, the edges of the skin were carefully approximated by horse-hair, a large Keith's drainage tube was placed in the cyst, and the wound was dressed as usual. The abdominal cavity had previously been washed out with sterilised water. The patient passed a good night after the operation and on the following day (the 20th) about two drachms of brown fluid were drawn off through the drainage tube. On the 21st it was noted that the patient had wheezed considerably during the night. About a drachm of fluid was removed. On the 22nd, the patient's temperature rose to 101·8° F., with a slight cough. There was a small patch of pneumonia on the right base posteriorly of about the size of a two-shilling piece. On the 23rd the diet was increased to three pints of milk in the 24 hours with tea and beef-tea. The pneumonia had increased in extent, but the patient was expectorating more freely. The wound was perfectly healthy; the respirations were 46 per minute. On the 24th the temperature had gone down with a run from 101·8° to 98°. The pneumonia had not differed much from the previous days; the respiration was much easier, being 33 per minute. The sutures were removed on the 27th day and from this time the patient made an uninterrupted recovery. On Oct. 1st she was practically well.

CASE 3. *Intussusception; laparotomy; recovery.*—A male infant, aged 11 months, was admitted into the York County Hospital on March 31st, 1899, under the care of Mr. Jalland, with the following history. He had had vomiting for 12 hours with mucous and bloody discharge from the anus. On admission there was a distinct tumour to be made out situated in the left hypochondriac region. It was moveable and could be shifted about in most directions, but freely to the right side of the abdomen. Under chloroform the bowel was thoroughly inflated by air, but this made no alteration in the size or condition of the tumour, so the abdomen was immediately opened in the median line two inches above and two inches below the umbilicus. The tumour was discovered in the left hypochondriac region. This was pulled outside and found to be the lower part of the ileum which was invaginated into the cæcum. The top of

the appendix only just appeared. This was reduced by pressure, being squeezed out, and the gut was returned into the abdominal cavity. The bowels were opened by an enema on April 2nd, and naturally every day afterwards. The wound was dressed on the 3rd and the stitches were taken out on the 6th, when the wound was found to be healed in the greater portion of its length. The child's temperature kept up for some time, but that was entirely due to the fact that he was teething. With that exception he had no bad symptoms and he was discharged from hospital perfectly well on May 13th. This shows the advantage of operating on these cases early, as the symptoms had apparently been in existence only 12 hours before admission.

CASE 4. *Cæsarean section; recovery.*—A woman, aged 21 years, was admitted into the York County Hospital on Sept. 25th, 1899, under the care of Mr. Jalland. Labour had commenced on the previous day, when she was seen by Dr. J. G. E. Colby of Malton, who found that her pelvis was extremely distorted and that the conjugate diameter was only two inches and sent her at once into the hospital, where she arrived at about 9 A.M. on Sept. 25th. Upon examination, finding there was no prospect of the child being delivered in the natural way, it was decided to perform Cæsarean section at once. Nitrous-oxide gas, ether, and chloroform were administered and an incision four and three-quarter inches in length was made in the median line, commencing about half an inch below the umbilicus, all the bleeding being stopped by pressure of the forceps. The abdominal wall was very thin and the uterus was almost immediately exposed. The wound was carefully packed round with sterilised pads and the uterus was opened by a vertical incision about three and a half inches long. The placenta was found immediately underlying it and some sharp bleeding occurred. The membranes were quickly separated by passing the fingers downwards and the liquor amnii was allowed to escape. The child was then delivered by drawing on the right leg. Some little difficulty was found in delivering the head. After ligaturing the cord the placenta and membranes were removed. The wound in the uterus was then sutured by four deep sutures, passed so as to include the muscular walls of the uterus (Fig. 3). Between these deep sutures

FIG. 3.



C U, cavity of uterus; S, S, line of suture.

several fine silk sutures were placed, carefully approximating the edges of the cut peritoneum. The abdominal cavity and pelvis were then washed out with sterilised water at a temperature of 110° F., some of which was left in. The abdominal wall was then sutured with half a dozen deep silkworm-gut sutures, including the whole of the constituents of the abdominal wall. A few horse-hair sutures were necessary to bring the edges of the skin together. The time of the actual operation was about 40 minutes. The child (a male) was alive and was delivered in 13 minutes. A hot vaginal douche was given before leaving the theatre. The patient made an uninterrupted recovery. The sutures were removed on Oct. 3rd, and on the 24th she and the child were both perfectly well.

*Remarks by* Mr. JALLAND.—I am a little uncertain as to whether the cyst in Case 2 was hydatid or not. There were no supplementary cysts discovered in it, nor apparently any cyst wall. Unfortunately the fluid was not examined, so the absolute nature of it was not determined. It may have been an old degenerated hydatid cyst or one of those simple cysts which are occasionally met with in the liver. In any case the result of the treatment was most satisfactory.

## GOVERNMENT CIVIL HOSPITAL, HONG-KONG.

A CASE OF TYPHOID FEVER; TWO RELAPSES; RECOVERY.

(Under the care of Dr. J. M. ATKINSON, Principal Civil Medical Officer, and Dr. J. A. LOWSON, Acting Principal Civil Medical Officer.)

A RELAPSE is very common in typhoid fever, and is often thought to be due to incorrect dieting, but this is probably not the case. Every rise of temperature after the fall to the normal in typhoid fever is not a relapse, but in a true relapse all the phenomena reappear. Two relapses are more rare, but three and even four[1] have been seen. For the notes of the case we are indebted to Mr. J. Bell, resident medical officer.

A young German, aged 25 years, was admitted into the Government Civil Hospital, Hong-Kong, on Jan. 7th with a history of five days' continued fever, headache, pain in the limbs, &c. The tongue was furred in the centre but was clean at the tip and edges. Gurgling was heard in the right iliac fossa. The temperature was 104° F. The continued fever lasted for 30 days, the temperature ranging mostly between 101° and 104°. There were crops of roseolar spots, splenic enlargement, and tenderness on pressure over the spleen, epistaxis occasionally, and delirium on the twenty-first day, with a feeble pulse of 144 and constipation. This last was most troublesome throughout the illness. From the thirtieth to the forty-first day the temperature was of the intermittent type, was normal or 99° in the morning and 100° or 103° (105° once) in the evening. From the forty-first to the fifty-fourth day (13 days) it remained normal, and on this day he had a dose of castor-oil followed by great pain in the abdomen with an evening temperature of 102°. The relapse lasted for 20 days, the temperature ranging between 100° and 104°, with dry furred tongue, retention of urine, a dry "rub" at the left base, and a bad pulse throughout. The temperature remained normal for 14 days (up to the eighty-seventh day), when the patient had a dose of two grains of cascara sagrada, followed by much abdominal pain and distress and an evening temperature of 101·8°. This (the second) relapse lasted for 13 days, the temperature varying between 100° and 103°, with low delirium, feeble quick pulse, and great depression. He slowly convalesced and was up for the first time on the one-hundred-and-twentieth day and was sent home to Europe after having been 149 days in the hospital.

*Remarks by* Mr. BELL.—Two relapses in typhoid fever being rare this case is reported as an instance of the amount of vitality possessed by some patients. He was not a robust young man, having been rejected, I believe, for the German army, and only weighing 108 lb. on the day of admission. The fact that throughout this long illness on an ordinary mattress there were never any signs of bed-sores speaks for the nursing, and the greatest credit is due to Sister Hope (Miss Franklin) and Sister Edith (Miss Maker) for the keen and intelligent interest which they took in the case throughout.

# Reviews and Notices of Books.

*Lectures on Clinical Medicine.* By JOHN LINDSAY STEVEN, M.D. Glasg. Glasgow: Alex. MacDougall. 1900. 8vo, pp. 195, with 37 Illustrations. Price 6*s*.

THIS book contains a series of 15 lectures delivered by Dr. Steven in the Glasgow Royal Infirmary. In the first lecture a full account is given of that rare and interesting disease known as Landry's paralysis, based upon two cases in one of which there was a post-mortem examination. No lesion was found in the central nervous system, but unfortunately the peripheral nerves were not examined. Lesions, as the author says, have undoubtedly been found by competent observers in the peripheral nerves. Changes have also occasionally been noted in the central nervous system. Thus it has been suggested, and not at all improbably, that

[1] Broadbent: Quain's Dictionary of

Landry's paralysis has been made to include more than one disease. Dr. Steven looks upon his cases as lending support so far as they go to the toxæmic theory of the complaint. Some attention is given here to the resemblances between Landry's paralysis and diphtheritic paralysis, but obviously the analogy must not be pushed too far.

Lecture II., on a Mediastinal Tumour Involving the Root of the Left Lung, illustrates the extreme difficulty which is sometimes experienced in the diagnosis of this affection, at least in its earlier stages. The author very properly emphasises the diagnostic importance of recognising any fulness or nodular projections beneath the clavicles or in the neck. A further case of malignant tumour about the root of the lung is described in Lecture VII. Here there were multiple tumours of the integument.

The Schott Treatment of Heart Disease comes under discussion in the third lecture. The author obviously thinks that this method of treatment has been over-estimated, but three cases however carefully studied will not allow of any wide-reaching conclusions being drawn.

Lecture IV., which is undoubtedly one of the most interesting of the series, contains a record of four cases illustrating the influence of syphilis in the production of alarming disorders of the nervous system. The first case was one of syphilitic hemiplegia with Jacksonian epilepsy in a man, aged 46 years, probably due to a gummatous affection involving the motor cortex. There were also present gummatous tumours of the scalp. Rapid recovery took place under mercury and iodide of potassium. This case reminds the reviewer of a similar case under his care which pursued a very varying course under anti-syphilitic treatment. Trephining was eventually had recourse to but unfortunately this patient succumbed and a localised gummatous affection of the meninges and cortex of one Rolandic area was found. The second case was one in which several of the eye muscles were involved and there was severe hemicrania. Complete recovery ensued under treatment with iodide of potassium and mercury. In the third case, of a man, aged 40 years, there were motor aphasia and marked paresis and rigidity of the right arm and hand, preceded by severe headache. There was reason to believe the disease to be of syphilitic origin but no improvement followed anti-syphilitic treatment. The last case occurred in a man, aged 37 years, who had severe and protracted headache with alarming convulsions and mental derangement of undoubted syphilitic origin. The headache and fits were relieved by prolonged mercurial treatment.

In Lecture V., on Infantile Jaundice, the mild form is carefully distinguished from the grave form, which latter is usually associated with serious organic lesions. The author relates in Lecture VI. an interesting case of a spastic hemiplegia following upon enteric fever and terminating in insanity. The patient had thrombosis of the veins in the leg and Dr. Steven thinks that the cerebral lesion was probably of a similar nature.

In Lecture VIII. a case of Marie's osteo-arthropathy, but without any pulmonary lesion, is related. Four cases of muscular atrophy are detailed in Lecture IX.; two are of the kind generally described as progressive muscular atrophy, the other two being of a still more doubtful nature.

In Lecture X. the author describes in detail a case, long under observation, of sclerodermia with hemiatrophy. In an appendix the post-mortem examination is related. Lesions were found in the right anterior horn of the cord and included changes in the multipolar cells and the formation of cavities about the vessels. The author thinks these lesions of the greatest importance in connexion with sclerodemia and hemiatrophy. Cases of multiple cerebral tumour and spastic paralysis, probably of myopathic origin, are related in Lectures XI. and XII. respectively.

The treatment of pleurisy with effusion by tapping is fully described and illustrated by cases in Lecture XIII. A valuable and practical summary of the subject will be found here. In Lecture XIV. a case of splenic leukæmia with a description of the characters of the blood in this disease is given. The last lecture deals with the subject of profuse hæmatemesis due to pore-like erosions of the gastric arteries. Two cases are recorded, in one of which the patient recovered under rectal feeding and saline infusion, but ultimately succumbed to an uncontrollable diarrhœa. In the other case death occurred notwithstanding that a laparotomy was performed. The abrasions in which the minute opening into the vessels are found may be readily overlooked because they are very superficial.

This series of clinical lectures provides some very interesting and instructive reading. The lectures are well written and are very practical. Collected together in this compact form they reflect, as Dr. Steven very rightly says in his preface, the varied nature of the work which falls to the physician in a large general hospital.

---

*The Principles of Bacteriology*. By A. C. ABBOTT, M.D., Professor of Hygiene and Director of the Laboratory of Hygiene, University of Pennsylvania. Fifth Edition. London: H. K. Lewis. 1899. Pp. xi.—590. Price 12*s.* 6*d.*

*The Hygiene of Transmissible Diseases: their Causation, Modes of Dissemination, and Methods of Prevention.* By A. C. ABBOTT, M.D., Professor of Hygiene and Director of the Laboratory of Hygiene, University of Pennsylvania. London: Rebman, Limited. 1899. Pp. 311. Price 14*s.*

OF these two books by Professor Abbott the first is a fresh edition of a work which we have had several occasions to review very favourably in these columns. The fact that a fifth edition of the "Principles of Bacteriology" should be called for within eight years of its first publication is a sufficient proof that our verdict has coincided with that of students and teachers of the subject generally. The character of the book has not been in any way altered in the present edition; it is somewhat increased in size owing to the introduction of some new illustrations and of a certain amount of new matter necessary in a rapidly growing subject where a book must be kept up to date. No alteration has been made in its price. Amongst other changes we may note that the chapter on Immunity has been largely rewritten and an account of Ehrlich's recent speculations on the subject introduced. Throughout the book there is evidence of careful revision, and its thorough and excellent character has been well maintained. It is a pleasure to us again to recommend it as a valuable and suggestive text-book both for students and teachers.

The second book, "The Hygiene of Transmissible Diseases," is not only a new departure for Professor Abbott, but to some extent a novelty in the literature of medicine. We cannot recall any one book which attempts to cover quite the same ground, though T. W. Thompson's section on "The Natural History of Infectious Diseases" in Stevenson and Murphy's "Treatise on Hygiene and Public Health" does so very nearly. The book is stated to reproduce in substance a certain portion of the lectures delivered by the author in his capacity of professor of hygiene in the University of Pennsylvania. It is universally admitted that "public health" has developed into so important a branch of medicine that it demands separate text-books and lectures. It is further becoming apparent that the "transmissible" diseases bulk so largely in public health and form so compact a subject that there is nothing inappropriate in their treatment in a separate book. If any justification for so doing were required it is, we think, to be found in the present volume. A vast amount of time and trouble is saved to the student by the collection in one small

volume of some 300 pages of the principal facts concerning the nature of infective diseases, their causation and prophylaxis, which otherwise must be sought laboriously in scattered medical literature. There are no novel facts brought forward—indeed, the writer has deliberately excluded all that is not well established. The merit of the book lies in the compact but lucid treatment of a mass of accurate and well-arranged detail on a definite branch of hygiene. The subject gains in interest by this collective treatment and the tables and diagrams which are freely introduced serve to enforce the lessons taught.

The general plan of the book is as follows. After some general introductory remarks, Section I. deals with the causation of disease and naturally of infective disease in particular. The writer adopts the usual terminology, speaking of the microbe as the direct or exciting cause and the various other factors (insanitary surroundings, sex, age, &c.) as predisposing causes. The different factors are discussed in detail and illustrative charts are introduced. We would suggest that in introducing "comparative mortality" tables it would have been well to state explicitly what such tables mean and how they are constructed. Section II., forming the larger part of the book, deals with the transmissible diseases in detail, that is, with the specific fevers and all other infective diseases, including the animal ento-parasites, such as tapeworms. There is no attempt to deal with the ordinary medical aspects of these affections. They are shortly defined, a brief account is given of the specific micro-organism where such is known, illustrated by a drawing or photograph, and then the distribution, modes of infection and dissemination, and details of prophylaxis are in each case discussed in full. Section III. deals with general prophylactic measures, commencing with a short and excellent critique of the theories of natural and acquired immunity. The various chemical and physical means of disinfection are then described in detail, and the book concludes with an account of the management of the sick-room in infectious cases and a short chapter on quarantine.

There is little room for criticism as to the care with which Professor Abbott has marshalled and arranged his facts. In his desire to avoid contentious matter he has abstained from mentioning in any detail the facts which have been collected in this country as to the conveyance of scarlet fever and diphtheria by the milk of cows believed to be suffering from analogous infectious disease, and which perhaps deserve more than the passing allusion which he makes to them. But he has included nothing which the student of hygiene ought not to be well acquainted with, and the style and manner in which the information is conveyed leave nothing to be desired. We heartily commend the book as a concise and trustworthy guide in the subject with which it deals and we sincerely congratulate Professor Abbott on having written so valuable a work.

## LIBRARY TABLE.

*Mock Nurses of the Latest Fashion.* By F. J. GANT, F.R.C.S. Eng. London: Baillière, Tindall, and Cox. 1900.—This little book is mainly a reprint of papers which appeared during 1899 in the *Medical Press and Circular*, but some additional chapters have been added to the original papers. Mr. Gant pleads strongly for the State registration of nurses, arguing that the uncertificated nurse may be an infamous and designing woman. That of late the term "nurse" has been made to cover those belonging to the oldest profession in the world there can be no doubt, and Mr. Gant's picture of masseuses is not overdrawn, but this masquerading of bagnios as adjuncts to medical treatment has now been suppressed by the police. Although there are some private nurses who are not all that they should be, yet Mr. Gant's pictures of the wicked private nurse are overdrawn. The book calls attention to an evil which doubtless does exist to a certain extent, but its message would have been far more forcible if it had been far less exaggerated.

*Silex Scintillans.* By HENRY VAUGHAN. London: J. M. Dent. Pp. 238. Price 1*s.* 6*d.* net.—This edition of a too little known work forms one of the volumes of the Temple Classics which Mr. Israel Gollancs is editing for Messrs. Dent. Vaughan was born in 1622 in the parish of Llansaintfraed, Brecon, being a twin with his brother Thomas. Henry went to Oxford and also studied law in London, but eventually turned his attention to medicine. Where he obtained his diploma is not known, but he commenced to practise as a medical man in 1645. His poems, although marked at times by the love of conceits so characteristic of the times in which he wrote, are generally of very high order. Few English or indeed any poets have written a more majestic passage than the opening of the poem called "The World":—

> "I saw Eternity the other night
> Like a great Ring of pure and endless light,
> All calm, as it was bright;
> And round beneath it Time, in hours, days, years,
> Driven by the spheres,
> Like a vast shadow moved, in which the world
> And all her train were hurled."

He was a good scholar and probably acquainted with the writings of the Neo-Platonists, and in the poem called "The Night" there is a curious echo of Dionysius the Areopagite. The last stanza of "The Night" begins:—

> "There is in God, some say,
> A deep but dazzling darkness ....."

and so Dionysius, "The divine darkness is that light inaccessible wherein God is said to dwell." Messrs. Dent are much to be congratulated for having afforded the opportunity of becoming acquainted with such a writer as Vaughan to many whose purses are not overburdened. The type and paper are all that could be desired.

# New Inventions.

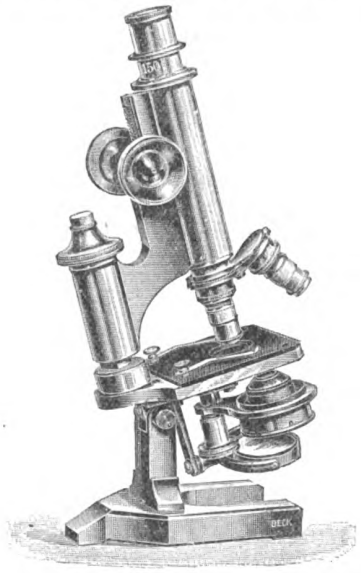
## A SANITARY DUSTBIN.

THE aim to make a dustbin strictly speaking a sanitary receptacle is admirable, and he who succeeded would indeed be recognised as a benefactor, since disease has often been traced to this unsatisfactory method of storing our dust and garbage until it can be taken away. Mr. George Olliver, of 21, Elder-place, Brighton, has made a definite attempt to construct a dustbin on sanitary principles. He has done this by constructing the bin with a base larger than the top with sides converging towards the upper ends but diverging towards the base. The front of the bin is inclined in a rearward direction from the lower to the upper end. The bin is also fitted with a sliding removable bottom, a removable sifter, and a removable lid turning on detachable hinges. The essential points in the construction of this bin would undoubtedly help towards a better state of things in regard to the condition of the refuse contained in it and its removal may be effected with the least possible nuisance arising. But whether it will serve as an improved means of storing and removing house refuse will depend entirely, as is the case with many another excellent appliance however well it may be designed, upon the way in which it is handled and upon what is put into it. Is there any conceivable thing which the ordinary domestic servant does not consider a fit object for the dustbin?

## THE "LONDON" MICROSCOPE.

A GOOD microscope is an essential part of a student's outfit, but makers have found it very difficult to produce microscopes with powers and definition strong enough to be useful at prices suitable to the student's purse. Certain continental makers have, moreover, been able to produce

microscopes for students at lower figures than the English makers have cared to attempt. Messrs. Beck of Cornhill have recently submitted a microscope to us which would seem to be a thoroughly practical instrument for students' purposes. We found it to give good definition and a flat field. The mirror in the cheaper microscope, which has no sub-



stage, works rather too close to the stand to be convenient, otherwise we have nothing but praise for the instrument. The illustration shows its appearance. The price of the instrument in a case, including stand, two objectives of two-thirds and one-sixth of an inch respectively, one eye-piece, and a concave and plain mirror, is £5 12*s.* 6*d.* The addition of the focussing substage and of the double nosepiece increases the price.

## OPENING OF THE MEDICAL SCHOOLS:

### WINTER SESSION 1900–1901.

#### LONDON.

*St. Bartholomew's Hospital.*—The session will begin on Monday, Oct. 1st. The old students' dinner will be held on the same evening in the great hall of the hospital, Mr. H. J. Butlin, F.R.C.S., in the chair.

*Charing-cross Hospital.* — The session will begin on Tuesday, Oct. 2nd, when the Right Honourable Lord Lister, P.R.S., will deliver the third biennial Huxley Lecture, on Recent Advances in Science and their Bearing on Medicine and Surgery. This lecture will be delivered in the Anatomical Theatre of the Medical School at 4 P.M. A conversazione will be given by the students' societies in the school buildings on the evening of Oct. 1st, and the old students' dinner will take place at the Hotel Cecil on Tuesday, Oct. 2nd.

*Guy's Hospital.*—The session will begin on Monday, Oct. 1st, on the evening of which day a house dinner of the Students' Club will take place in the college dining hall. Application for tickets to the dinner should be made to Mr. A. W. Ormond, the secretary of the Students' Club, Guy's Hospital, S.E. The first meeting of the Physical Society will be held in the new Physiological Theatre at 8 P.M. on Saturday, Oct. 6th. Sir Samuel Wilks, Bart., F.R.S., will preside, and a paper will be read by Mr. F. Curtis, Notes from an Ornithological Cruise in the North Polar Seas. After the meeting a conversazione will be held in the new laboratories and class-rooms. All past and present students are cordially invited to the meeting.

*St. George's Hospital.*—The session will begin on Monday, Oct. 1st, with an introductory address by Dr. F. G. Penrose, physician to the hospital. The distribution of prizes will take place early in November, and will be made by Sir Michael Foster, M.P., F.R.S., &c.

*King's College Hospital.*—The session will begin on Monday, Oct. 1st.

*London Hospital.*—The session will begin on Monday, Oct. 1st. The old students' dinner will be held in the college library, Dr. Gilbart Smith in the chair.

*St. Mary's Hospital.*—The session will begin on Monday, Oct. 1st, at 3.30 P.M., with an introductory lecture by Mr. H. S. Collier, surgeon in charge of out-patients to the hospital, and lecturer on practical and operative surgery in the medical school. The annual dinner of past and present students will take place on Wednesday, Oct. 3rd, at the Whitehall Rooms, Hôtel Métropole, Dr. W. B. Cheadle, senior physician to the hospital, in the chair.

*Middlesex Hospital.*—The session will begin on Monday, Oct. 1st, at 3 P.M. Dr. T. Clifford Allbutt, regius professor of physic in the University of Cambridge, will distribute the prizes gained during the previous year and deliver an address. The annual dinner of the past and present students and their friends will take place at the Trocadero the same evening at 7 o'clock precisely, Mr. William Lang in the chair.

*St. Thomas's Hospital.*—The session will begin on Tuesday, Oct. 2nd. The prizes will be distributed by Sir William Mac Cormac, Bart., K.C.V.O., in the Governors' Hall on Tuesday, Oct. 2nd, at 3 P.M. During the afternoon the various departments of the hospital and school will be open for the inspection of visitors. The annual dinner, in which all former and present students are invited to join, will take place the same evening at the Whitehall Rooms, Hôtel Métropole, at 6 for 6.30 o'clock, Dr. C. Taylor Aveling in the chair.

*University College Hospital.*—The session will begin on Monday, Oct. 1st, at 4 P.M., when the Dean's report on the progress of the medical school will be read, after which an introductory lecture will be delivered by Professor G. Vivian Poore.

*Westminster Hospital.*—The session will begin on Monday, Oct. 1st. The annual dinner will take place on the opening day, Dr. William Henry Allchin in the chair. The secretary of the dinner is Mr. E. Canny Ryall. The annual distribution of prizes will take place during the session.

*London (Royal Free Hospital) School of Medicine for Women.*—The school will reopen on Monday, Oct. 1st, when the introductory address will be given by Miss L. B. Aldrich-Blake, M.D., M.S. Lond.

*London School of Tropical Medicine.*—The session will begin on Monday, Oct. 1st.

*Pharmaceutical Society of Great Britain.*—The inaugural address will be given on Oct. 1st, at 3 P.M., by Professor W. Ramsay, F.R.S., of University College, London.

#### PROVINCIAL.

*University of Birmingham.*—The session will begin on Monday, Oct. 1st.

*Yorkshire College, Leeds.*—The session will begin on Monday, Oct. 1st.

*University College, Bristol.*—The session will begin on Monday, Oct. 1st.

*University College, Cardiff.*—The session will begin on Monday, Oct. 8th. The introductory address will be delivered by Sir J. Williams on Wednesday, Oct. 10th.

*University College, Liverpool.*—The session will begin on Monday, Oct. 1st. The Lord Bishop of Liverpool will give the opening address and distribute the medals and prizes on Saturday, Oct. 13th, at 4 P.M.

*Owens College, Manchester.*—The session will begin on Monday, Oct. 1st.

*University of Durham.*—The session will begin on Monday, Oct. 1st.

*University College, Sheffield.*—The session will begin on Monday, Oct. 1st.

#### SCOTLAND.

*Anderson's College, Glasgow.*—The session will begin on Thursday, Oct. 18th.

*St. Mungo's College, Glasgow.*—The session will begin on Thursday, Oct. 18th.

*Queen Margaret College, Glasgow.*—The session will begin on Friday, Oct. 19th.

#### IRELAND.

*Queen's College, Belfast.*—The session will begin on Tuesday, Oct. 16th.

*Queen's College, Cork.*—The session will begin on Thursday, Oct. 18th. The lectures will commence on Monday, Oct. 22nd.

*University of Dublin.*—The session will begin on Monday, Oct. 1st.

# THE LANCET.

*LONDON: SATURDAY, SEPTEMBER 8, 1900.*

IT would be difficult to exaggerate the credit due to the Bishops for their interest in the promotion of legislation for effecting temperance reform. The remarkable discussions in Parliament during the late session must have convinced the Government that both parties in the State are of opinion that Parliament has yet more duties to discharge in connexion with the "superfluous drinking" of the country. The reluctance of the Government to undertake such legislation has impressed both its supporters and its opponents. The preoccupation of the country in the present session has been so complete as to give some colour of excuse to this reluctance, but enough has happened even this year both in the House of Commons and in the House of Lords to show that the country is in no mood to allow the results of the work of the Royal Commission on the Liquor Laws to be regarded as waste-paper. It was inevitable that there should be some difference of opinion in the Commission, but the enormous pecuniary interests involved and the popular habits of the nation were a security that no free play would be given to intemperate teetotalism desiring to treat men as children and Englishmen as Mahomedans. On the other hand, various influences have come into play in the cause of true temperance which cannot be ignored. Some great physicians and surgeons have sounded a note of warning and made it clear to all intelligent people that the present scale of consumption of alcohol has no reason in sense or science, and that alcohol generates disease wholesale, physical and mental, and is responsible for 25 per cent. at least of our insanity and for a very large proportion of our vice and crime. One of the most remarkable facts in this discussion of late years has been the significant and ominous emphasis with which our military leaders have advocated temperance and have insisted on the partial or total exclusion of alcohol from the diet of their troops in time of war. The tone of their testimony could scarcely have been more earnest if they had seen some great catastrophe due to the careless use of alcohol. We all know how disastrous the habit of drink may become in the case, say, of a medical man charged with the care of an individual life at a crisis of accident or disease. *A fortiori* is the use of alcohol fraught with peril to men who are charged with great responsibilities as are soldiers and sailors. This has been now widely recognised, and above the enjoyment of alcohol which characterises us as a nation there has risen a public opinion—intelligent, moral, and religious—which demands that alcoholism shall be restrained, and must be restrained if sanitation and social happiness are to be advanced, and if the nation is to hold its own in the new era of responsibility and competition on which all living and dominant races are now entering.

Amongst the forces which will compel politicians and statesmen to deal with the vice of drunkenness, or as the majority of the Royal Commissioners euphemistically put it, "superfluous drinking," the Bishops have ranked themselves most creditably and they have been well supported by their own clergy and by the ministers of all denominations. They have not contented themselves with setting a good example, but in their elevated place in the legislature they have spoken with no uncertain sound and they have succeeded in showing that in the House of Lords there is a strong feeling in favour of legislation. Since that memorable debate, in which the Bishops nearly defeated the Government, they have occupied themselves in putting into the form of a Bill, or rather of three separate Bills, their legislative proposals, based on those recommendations which were practically assented to by both parties in the Royal Commission. These Bills do not by any means exhaust the recommendations so assented to, and we miss two or three in particular to which we are inclined to attach importance. One of these would very properly give to the licensing authority full control over all "off" wine and spirit licences, including those granted to grocers and restaurants. The demoralisation of women by the grocer's licence is a matter of general belief. Little is said about the demoralisation of the grocer's business by the introduction of the sale of alcoholic drinks, but it is very real. The groceries now play quite a secondary part in the business and tend to recede more and more into back premises. In any new Bill full authority over this kind of licence must be given to the licensing authority. It is vain to talk of curtailing the number of public-houses, perhaps at a great cost, and then to leave uncontrolled the enormous extension of the trade in alcohol which is involved in licences for its sale granted to grocers, confectioners, and druggists. Other points which are not, we think, included in the draft bills of the bishops are control of the licensing of old-fashioned beerhouses, the sale of drink to children under 16 years of age, and the employment by licensing authorities of persons of some social standing to visit and occasionally report on the condition of licensed premises. We attach great importance to this last recommendation, which is made both in the report of the majority and in that of the minority of the Commissioners. It is scarcely to be expected that the police, familiarised with the drunkenness of the street—which, by the way, all the Commissioners regard as an offence—should have a quick eye to the irregularities of publicans. It is highly desirable that there should be a certain number of men of higher position who should inspect the licensed houses of a district.

These are details and they do not touch the underlying question of compensation. This matter must be faced and settled by the Government of the day, fearlessly and on right principles. As a profession we medical men can and should help the Government and urge it to the discharge of this great duty. Every year adds to the difficulty of it. They are no friends of Parliament who advise it to remain with folded hands and cry "non possumus" on this subject. The enormous expenditure on drink—even if drink itself were innocuous—implies a corresponding abstraction of wealth from useful and beneficial uses. But drink is not innocuous. It is the most powerful and fascinating of al

means of degradation and disease which unfortunate human nature can find to debase itself. Every medical practitioner sees illustrations of this almost every day of his life. The drunkenness of women is increasing. Many think that this begins with the grocer, but it certainly does not stop there, for women enter the public-houses in great numbers everywhere. It would seem to us fitting that before the new Parliament begins its duties and even before it is elected the leaders of the medical profession should combine to convince the front-bench representatives of the great political parties that the alcohol question is above all party interests, and that in dealing with it they should act together and act with all their strength. The bishops have set us an example and we of the medical profession have also our religious duties.

---

QUESTIONS have lately arisen (1) as to whether it would be legal to conduct occasional dissections of a part of a human body upon private premises not duly licensed for the practice of anatomy; and (2) if such dissections took place upon whom, if discovered and pronounced illegal, the penalty would fall. The Act regulating schools of anatomy is the Anatomy Act, 1832 (2 & 3 Will. IV., c. 75). The idea of the Act was to check the irregular practice of anatomy and the abuses to which such practice gave rise. The practice even led to murder in order to get an ample supply of bodies. Briefly summarised the Act gives to the Secretary of State for Home Affairs the power to grant licences to practise anatomy and to appoint inspectors for schools of anatomy, and it regulates the removal of dead bodies for the purpose of anatomical examination. It also permits (Section 10) "any Member or Fellow of any College of Physicians or Surgeons or any Graduate or Licentiate in Medicine, or any person lawfully qualified to practise medicine in any part of the United Kingdom, or any professor or teacher or student of anatomy, medicine, or surgery having a licence from the principal Secretary of State [in Great Britain] or Chief Secretary [in Ireland] to receive or possess for anatomical examination or to examine anatomically the body of any person deceased" if permitted by the person in lawful possession of such body, &c. But it forbids (Section 12) "any party to carry on or teach anatomy at any place, or at any place to receive or possess for anatomical examination, or examine anatomically, any deceased person's body after removal of the same, unless such party, or the owner or occupier of such place, or some party by the Act authorised to examine bodies anatomically, shall, at least one week before the first receipt or possession of a body for such purpose at such place, have given notice to the said Secretary of State or to the Chief Secretary of the place where it is intended to practise anatomy."

Throughout the Act the word "body" is alone used; and the question arises as to the application of the Act to parts of a body. Would it be lawful to dissect an arm or a leg or a brain on private premises unlicensed for the study of anatomy? In these days of private tutors and "coaches," and of the increasing numbers of students who enter for degrees in science as apart from degrees in medicine, but who want to do a course of practical anatomy, the question is one of some importance. On a literal reading of the law there does not appear to be any objection whatever to limited dissection on unlicensed premises. The Act deals with "bodies" and "bodies" alone. It assumes or expressly states all the way through that anatomists are concerned with "bodies" alone and not with parts thereof. It makes no provision to check the coöperative purchase of a body and the distribution of its component parts for dissection on premises other than those to which the body has been removed. Would the buyer and remover of a leg or a brain, or any other person concerned in buying or removing, come under the penalties set out in Section 18 of the Act? Would a student who conducted dissection of such parts in private be liable? Would the owner or occupier of such place become liable? It scarcely seems that he would be directly liable, but he might indirectly be brought within the grip of the law if, as would perhaps be the case, Section 12 (already quoted) were held to cover all practising or teaching of anatomy, whether the subject be a whole body or only a part. The exact words, as already quoted, refer only to "body"; but the words "it shall not be lawful for any party to carry on or teach anatomy at any place unless such party, &c., shall give notice, &c.," might be held to apply to a part of a body. The interpretation would be strained and scarcely justified at all if the words of the paragraph be read together, and if the words as to giving notice "at least one week before the first receipt or possession of a *body*" be borne in mind. But it is obvious that were such a course allowed as the removal of a portion of a body for the purposes of anatomical examination to any place other than that to which the body was originally consigned in accordance with the Act, the irregular practice of anatomy would become extremely difficult to prevent; and the practice of anatomy in any form in a private house must of necessity be objectionable for sanitary reasons, as well as for the sinister reasons that led to the passing of the Act.

A curious difficulty might arise under Section 13 of the Act even if it were held that no offence had been committed under Sec. 12 or any other section. Sec. 13 provides that every such body removed for anatomical purposes shall be placed "in a decent coffin or shell," and the party removing the same shall arrange for its decent interment in due course. Now if "such body" were deprived of an arm or any portion for private dissection elsewhere would the body to be buried be such body as was removed? Apparently on a strict reading of the law it would be necessary to reconstitute "such body" by bringing together again any part removed for dissection elsewhere before the burial of "such body" could take place as contemplated by the Act. It would be a terrible strain on the words of the Act to maintain that any *portion* carried about must be in a decent coffin or shell, as the use of the term "body" is so explicit. What after all is a body within the law? How many of its members may be lost or removed before it ceases to be a body or a corpse? No legal decisions are traceable on these points. On the whole it would be safer for "coaches" in anatomy and for students who desire to dissect in their homes to apply for a licence before practising anatomy on unlicensed premises, or permitting or conniving in any way whatever at such dissecting. Licences can be obtained by any of the persons enumerated in Section 10 "on

application from such party for such purpose countersigned by two justices of the peace acting for the county, city, borough, or place wherein such party resides, certifying that to their knowledge or belief such party so applying is about to carry on the practice of anatomy." The fee payable to the Exchequer on the grant of a licence is only £2 2*s*., but offences against the Act are misdemeanours and on conviction are punishable by imprisonment for a term not exceeding three months or by a fine not exceeding £50, at the discretion of the court.

---

ONE of the most interesting discussions at the recent meeting of the British Medical Association was that on "The Pathology of Cirrhosis of the Liver in Adults and Young Children." The discussion was opened by Dr. ARTHUR VOELCKER, who commenced by giving an interesting historical survey of the views held by various authorities from the time of LAENNEC, who was the first to employ the term "cirrhosis" as applied to the liver. Dr. VOELCKER naturally laid stress upon the efforts that had been made to establish satisfactory classification of the varieties of hepatic cirrhosis. The usual classification adopted was to divide the cases into two main divisions—namely, atrophic and hypertrophic. Some observers were of the opinion that there was no essential distinction between these two forms. An examination of a number of sections of cirrhotic livers had left Dr. VOELCKER with the impression that there was a very distinct difference between the peripheral and the intercellular forms. He considered that while it was true that in the peripheral forms (the multilobular and monolobular forms) a slight degree of intercellular sclerosis existed and while in the intercellular form a slight degree of peripheral sclerosis was met with, yet there was never any difficulty in determining to which category the chief change should be referred; though he did not think that a microscopical section would enable the physician to form an accurate idea of the naked-eye appearances of the organ. Much of the interest of the discussion was derived from the different views as to the origin of the connective tissue apart from the variety—that is to say, as to whether the primary change was in the liver cell and the cirrhosis secondary to this, or whether the fibrosis was primary and the changes in the liver-cells secondary. Dr. VOELCKER regarded cirrhosis as a widespread, recurrent, chronic, degenerative process associated with regeneration of the parenchyma. Opposed to this view was the one that the changes in the liver cells were secondary to the presence of the connective tissue. Although it is true that degeneration of the liver cells is found with cirrhosis, yet the speaker maintained that there was no relation between the amount of cirrhosis and the degree of degeneration. Dr. VOELCKER, after quoting other authorities, suggested that it seemed to be most reasonable to see in cirrhosis of the liver the effects of one or more poisons both in the liver cells and in the connective tissue, and the occurrence of degenerative or regenerative processes would depend on the nature of the poison and on the power possessed by the liver cell to resist it. Professor FLEXNER brought forward experimental evidence that lesions of the liver cells precede changes in the connective tissue, and demonstrated from his specimens the existence of a considerable amount of newly formed elastic tissue in addition to the connective tissue so universally recognised. Dr. LAZARUS-BARLOW from his observations drew the inference that in the case of hepatic cirrhosis there was first a destruction of the hepatic cells themselves, either as the result of the action on them of alcohol or of some form of bacterial poison, and that subsequently there occurred an over-growth of the normal fibrous tissue of the liver to fill up potential lacunæ. He further urged that in any microscopical picture these features would be found side by side; but since the destruction of hepatic cells must be a more or less gradual process—otherwise the onset of the disease would not be so insidious as it undoubtedly was—there was every reason to expect that signs of a rapidly forming and young fibrous tissue would be wanting, and this was found to be actually the case.

Another feature of the subject which occupied the attention of the meeting was the experimental production of hepatic cirrhosis. This aspect in the etiology of the condition has had great attractions for investigators, but a study of the work up to now accomplished by no means convinces us that the suggestion (first brought into prominence by Professor ADAMI) that cirrhosis of the liver is due to a specific micro-organism has been proved by experiment. It is true that localised patches of cirrhosis have been produced in certain lower animals by the injection of bacteria or their products, but no widespread increase of the fibrous tissue, as is seen in hepatic cirrhosis in man, has yet resulted. Mr. A. G. R. FOULERTON presented a contribution to the discussion from Professor LUDVIG HEKTOEN. His investigations showed that in guinea-pigs the subcutaneous injection of about one cubic centimetre of a bouillon culture produced in addition to local changes beneath the skin necrosis with cirrhosis of the liver. These results were, however, by no means constant and in other animals (dogs and mice) the condition of the liver was still less altered. The author of the paper himself went no further than to say that "the observations had seemed to him to be of some interest in their suggestiveness of a somewhat similar course of events in some instances of human cirrhosis." Dr. THEODORE FISHER argued that as some of the acute and sub-acute inflammations of the kidney were due to septic micro-organisms or their products, an interstitial hepatitis might arise in the same way, and he quoted cases which seemed to him to bear out the view suggested by the experiments of Professor HEKTOEN. It is undoubted that occasionally fibrous changes may be produced in the liver by the action of micro-organisms, but there seems to be no proof that the condition generally understood by the term "cirrhosis of the liver" is brought about in this manner. The remarks of Dr. VOELCKER on this point were forcible and even convincing. His experience in morbid anatomy has convinced him that in necropsies in patients who have died after diphtheria, typhoid fever, and other infectious diseases, cirrhosis of the liver is by no means common, and yet if that condition were due solely to bacillary infection these are precisely the cases in which it might be expected that such fibrous changes would be found. And he further pointed out that the chief ages at which cirrhotic livers were found were either in the first two or three years of life or between

the ages of eight and 10 years, and then not again until after 25 years; from this he concluded that the severe and frequent intestinal catarrh, undoubtedly of bacterial origin, to which children of all ages were so prone, could have little, if any, effect on the production of the cirrhosis.

The discussion was of genuine value, for it furnished an opportunity for taking stock of our knowledge of the pathology and etiology of hepatic cirrhosis. That observers are still not unanimous on the many points mentioned in the debate was quite evident; but it was also demonstrated that much useful work is being done in the direction of elucidating the true nature of a common affection. The pathology of cirrhosis of the liver must still be the subject of investigation probably for some time, but such debates do much to stimulate the work of the observer. New recruits are gained to pathology and workers are encouraged either to persevere upon their old lines or to adapt their methods to the methods of other workers—all of which things make for eventual knowledge.

---

A CONSIDERABLE amount of interest has been excited by the case of alleged cruelty to a lunatic which was recently decided at Bow-street Police-court. We shall briefly review the facts of this case as revealed in the course of the magisterial examination. ROBERT EDWARD HUTTON, aged 36 years, was a congenital idiot and had resided with his brother, Mr. JOHN HUTTON, who is a medical man, since 1892. A sum of from £80 to £90 per annum was allowed for his maintenance. Until about six months ago he lived in his brother's house, but then his habits, it is alleged, having become objectionable, another arrangement was made. The manner in which this was carried out was as follows, the facts being elicited from witnesses under examination. A bed, bedding, and a few chairs were placed in a harness-room at the end of the stable-yard attached to the dwelling-house. This was the lunatic's sleeping apartment. Close at hand in the yard an area six feet by four feet was fenced off and partly roofed over. A seat was placed within it. This inclosure served as a kind of outside sitting-room for the imbecile. No regular attendance appears to have been provided beyond the services of the coachman attached to the establishment. It was asserted by some witnesses that actual cruelty was resorted to at times and that Mr. JOHN HUTTON had used a cane when his brother was refractory. The evidence on this point was somewhat conflicting, but it was admitted by the defence that a cane had been used chiefly to frighten but occasionally for the purpose of chastisement.

Legal and medical opinions on the case were not quite in accord. Dr. NICOLSON, C.B., one of the Lord Chancellor's visitors in Lunacy, who visited the house under an order of the Lord Chancellor, stated his view that the conditions of the imbecile's life there were prejudicial to him, since he did not receive that careful and constant attention which he required. Dr. HENRY MAUDSLEY, who also visited the house under instructions from the Lord Chancellor, gave similar evidence. Sir FRANKLIN LUSHINGTON, the chief police magistrate for London, who heard the case at Bow-street, himself paid a visit of inspection. His view was that every reasonable care had been taken for the personal comfort of the poor lunatic, and further that the allegations of actual cruelty rested upon no solid foundation. As regards the accusation of cruelty, which is in some ways the most important element in the case, we quite believe that the opinion of the learned magistrate was the right one. And we are glad to think that no grounds exist for suspecting a member of our profession of cruelty towards an unfortunate being who had the double claim on him of being an idiot and a brother. We are, however, convinced that the view taken by Dr. NICOLSON and Dr. MAUDSLEY on the question of adequate supervision and attention is the more correct. We cannot but think that a serious error of judgment was committed in the arrangement by which the lunatic was removed from the shelter of the house and allowed to spend his nights and much of his daily life by himself. Such unfortunate persons require more constant care than other people. For want of this care an accident may occur at any time, and it was by luck rather than through domestic or professional forethought that such an accident did not actually occur. The effect of isolation, moreover, is always more or less to aid a process of mental deterioration where this is present, and it would have been better in every way had this unfortunate sufferer been kept in contact with interesting surroundings. In the end the only offence proved in this case against Mr. JOHN HUTTON was the technical one of housing a lunatic for profit without the customary licence. Such an error might under the circumstances have been almost disregarded, and as a matter of fact very slight importance was attached to it. The position of the imbecile up to the time of his removal from his brother's house was practically that of a boarder among relations, and it was so in virtue of a family agreement conceived with the best intentions. This fact was recognised and only a nominal fine was imposed. The defendant's coachman, who was largely left in charge of the lunatic, was fined £5 for cruelty.

The well-being of lunatic patients, as is now generally admitted, is most surely guaranteed when they are committed to the care of strangers. Experience has abundantly proved that the influence of a relative, however well-intentioned, is not only not salutary, but is even prejudicial. There is a tendency on the part of relatives to be either too kind or too severe. Moreover, we must take into account the reliance which most invalids place on those with whom they are familiar. This reliance constantly opposes by its mere inertia that awakening of the curative power of will which it is the object of all mental treatment to encourage. Then, again, the watchfulness that must be maintained in view of the volcanic impulses of the insane person furnishes another strong reason for his removal to an establishment where it is the every-day rule of the place to anticipate mental explosions. Such a course argues no unkindness but the contrary, due regard being had, of course, to the character of those in whose care he is placed. In the present instance it has proved regrettable in more ways than one that the home system of treatment was preferred, though doubtless the primary motive which prompted this course was that of parental goodwill. Although Mr. HUTTON is himself cleared of the

accusations of cruelty the man whom he constituted his brother's attendant has been fined for cruelty. Again medical men will surely endorse the views of Dr. NICOLSON and Dr. MAUDSLEY that from a medical point of view Mr. HUTTON did not do the best possible for his brother. Granted that he did all that he could in the circumstances, it remains that the circumstances were wrong. The environment in which the lunatic was kept was entirely unsuitable to his condition, and the personal kindness of Mr. HUTTON did not counterbalance the disadvantages of the surroundings.

# Annotations.

"Ne quid nimis."

## THE WORK OF SIR JOHN BENNET LAWES.

IT is most satisfactory to learn that the magnificent work of research which the late Sir John Bennet Lawes commenced in 1837 is to be carried on in perpetuity, according to the provisions of a trust deed which Sir John Lawes executed in 1889. The world-famous Rothamsted experiments do not therefore cease with the death of the man who founded them. This is all the more fortunate since we are only just beginning to learn the nature of the rôle of bacteria in aiding certain plants directly to assimilate the nitrogen from the air. It is curious that the wonderful series of experiments which Sir John Lawes instituted should have led him to the positive belief that plants derived their nitrogen solely from the soil. Before, however, it became known with certainty that bacteria aided in the fixation of nitrogen directly from the air, Sir John Lawes, with his able partner in research Sir J. Henry Gilbert, observed that whilst the nitrogen in most crops can be accounted for by the combined nitrogen supplied to the land in the form of manures and in rain water, yet in the case of particular leguminous crops, such as peas and beans, there is a quantity of nitrogen acquired which cannot be accounted for as being derived from these sources. Chiefly by the conclusive experiments of two German investigators, Professor Hellriegel and Dr. Wilfarth, and of a Frenchman, M. Berthelot, we now know that this nitrogen is derived from the atmosphere, and further that this assimilation of free nitrogen is dependent upon the presence of certain bacteria flourishing in and around the roots of the plants. The greatest of all arguments in favour of this view is that when the soil is sterilised no such fixation of atmospheric nitrogen takes place. Some go so far as to say that microbes made our nitrate kings, the huge beds of Chili saltpetre being regarded as products of the nitrifying organism. Recent investigation has shown that each particular leguminous plant is provided with its own particular micro-organism which leads to the fixation of free nitrogen. Cultivations of these organisms are now prepared for inoculating the soil by means of which the availability of nitrogen is increased which benefits the particular crop. The cultures known as "nitragin" are supplied on a commercial scale to agriculturists, and so far the results have been promising. To Sir John Lawes we owe practically all our knowledge of the requirements of all kinds of growing crops. He showed when nitrogen was needed, when potash was indicated, and when phosphates were demanded. The fruitful observations which he made on these points led to the establishment of an enormous industry in which England still leads the way—namely, the manufacture of artificial fertilisers. He showed how phosphates could be made available for the building up of the plants by treating the insoluble lime salt with sulphuric acid, which results in the production of a soluble acid phosphate known commercially as super-phosphate. Again, Sir John Lawes pointed out the advantage of dressing the ground with ammonia and nitrates, and this discovery of how to minister to plant life has had an enormous influence on the industry and wealth of the world. Ever practical in carrying out his ideas, Sir John Lawes was not behind as a student and exponent of pure science, and the journals of the learned societies contain a wealth of scientific contributions from his pen. A great man has indeed passed away in the person of Sir John Bennet Lawes; but, more fortunate than many great men, the labour of his life will ever remain as a monument of his genius and of his devotion to the best interests of mankind.

## THE ART OF DIAGNOSIS.

THE best reason for cultivating the art of diagnosis is that it is at the root of all success in the practice of medicine. For good practitioners this reason will supersede all others, but there is another one that may be more efficient as a stimulus to some—viz., the fact that in regard to a large section of the cases of infectious disease there is a chance of errors of diagnosis being detected and even published. This fact is illustrated in every edition of the annual report of the Metropolitan Asylums Board Hospitals. In the last number of the report for the year 1899 a list of such errors is given. The principal of these have regard to scarlet fever, diphtheria, and enteric fever. In the case of scarlet fever the errors were 3·9 per cent.; of diphtheria, 7·4; of enteric fever, 17·3. Some error is almost unavoidable, but it should be reduced to a minimum. It is gratifying to know that in regard to all these the percentage of error is considerably less than in the previous year, which we may take as a sign that more care is taken by practitioners and that the provisions for instruction which the cases in the hospitals of the Board afford are appreciated by students. The improvement in the diagnosis of enteric fever is very marked. The great safeguard against error in this disease is not to be in too great a hurry in coming to a diagnosis. A variety of symptoms must be taken into account before other diseases can be excluded.

## TUBERCULOSIS IN A FRENCH NAVAL ARSENAL.

DR. AUFFRET, principal medical officer of the Maritime Arsenal at Brest, does not believe implicitly in statistics, because "the elements from which they are compiled are so seldom gathered under identical conditions." To be of use statistics should, he thinks, not only extend over a lengthened period and be pervaded by a single ruling idea, but, above all, it is necessary that throughout the entire series the same directing hand should control the helm. These three essentials are unfortunately rarely united. And when the prophylaxis of a grave affection like tuberculosis is in question something more than probabilities are needed if we would avoid the imparting of a false direction to our reforms and the throwing away of large sums of public money. Notwithstanding his cautious attitude, Dr. Auffret found it impossible to escape concluding from the records at his disposal that, in spite of modern sanitary discoveries and inventions, the mortality from tuberculous affections amongst the *personnel* under his charge instead of decreasing, as might have been expected, has increased steadily during the past 30 years, until at last very nearly 70 per cent. of the total loss from internal disease could be ascribed to it. The number of operatives and clerks employed in the arsenal being close on 8000—a

strength which has not been equalled, or even approached, since 1871, the year of the war with Germany—the matter is one of considerable importance and accordingly Dr. Auffret was led to institute a minute inquiry into the causes of the mortality with a view to suggesting remedies. The results are embodied in a report to the Minister for Marine Affairs, which was submitted last December, and an abstract of the document appears in the *Archives de Médecine Navale* for June where it occupies three-fourths of the entire space. Among the predisposing causes of the disease the writer mentions (*a*) complaisance or carelessness on the part of examining medical officers. When a candidate with incipient tubercle is allowed to pass he at once becomes a centre of infection. The prevalence of the disease is chiefly due to the personal transmission of germs. (*b*) Defective buildings, walls, and floors; (*c*) insufficient and excessive ventilation; (*d*) overcrowding; (*e*) certain occupations; (*f*) climatic vicissitudes. The mortality from tuberculosis invariably attains to its maximum during the two months that follow the period of greatest cold. (*g*) Home influences. A workmen passes more than half of his time out of the reach of official sanitation. (*h*) Improper food. 85 blacksmiths in consideration of their arduous work receive an extra allowance of wine. "Why should this be?" inquires Dr. Auffret. "It is contrary to the teaching of physiology dating back upwards of 50 years. Our neighbours, who are also our rivals, give additional meat when the work is hard in the form of 'rosbeef'—that is to say, of roasted beef." He proposes, therefore, the substitution of grilled meat in lieu of half the wine. In conclusion, Dr. Auffret says: "At Brest the damage caused by tuberculosis every year may be put down as equal to a sum of from 40,000 to 45,000 francs. I propose to utilise this money in pensioning off men the moment they begin to exhibit symptoms of tuberculosis. The elimination of the poison-carrying workman cannot but lead to a diminution in the number of fresh tuberculous cases and consequently to the progressive lessening of the sum to be distributed." In Dr. Auffret it is clear that France has a capable clear-headed official.

## CURARE IN TETANUS.

DR. B. SCHARLAN[1] states that curare had never met with general favour in the treatment of tetanus, Billroth in his great work on Surgical Pathology and Therapeutics (1871) remarking that it had been used occasionally but had not fulfilled expectations. The following record, however, of two cases of tetanus and trismus treated by curare with recovery in both is interesting. The first case was as follows. A boy, aged 11 years, was admitted to hospital on August 29th with marked trismus and tetanus lasting two days and following upon a wound in the foot inflicted by a splinter of wood four weeks previously. Two weeks after the wound there was pain in the right shoulder, soon after the entire trunk became rigid, and on the following day the neck and arms became involved. Attacks of trismus and tetanus followed later. There was very marked opisthotonos, the abdomen was rigid and tense, micturition was difficult, the temperature oscillating about 100° F. Treatment commenced with a hypodermic injection of one-twelfth of a grain of curare repeated in increasing doses as often as the physiological symptoms of a dose faded away. When a dose of one quarter of a grain was reached the opisthotonos disappeared and the patient was able to open the mouth sufficiently to separate the teeth and drink. To secure sleep at night chloral hydrate was given in the evening. The injections of one quarter of a grain of curare were repeated at first every six or eight hours, but after six days of such treatment the effect became more lasting and only two injections were required in the 24 hours. From Sept. 12th one injection daily was given until Sept. 20th, when it was discontinued. He was after this given a warm bath of 30 minutes' duration every morning. He improved, and on Oct. 5th he was discharged as cured. The second case was that of a boy, aged seven years, with tetanus and trismus, admitted to hospital on Oct. 31st. There was extreme opisthotonos, the superficial and deep reflexes were exaggerated, the temperature was 101·4°, the pulse was 132, and the respirations were 42. The pure alkaloid curarin was given, the dose being one-fiftieth of a grain hypodermically. About 30 minutes after the injection the mouth was somewhat opened and the arms became lax, but the legs remained as rigid as before. Five grains of chloral hydrate were given nightly. The injections of curarin were continued on the same principle as in the previous case. The patient continued to improve day by day. On Nov. 5th he slept six hours during the night, the muscles being quite relaxed. The next day he sat up in bed for the first time. Eventually the stiffness of the jaws and legs entirely passed away and he was discharged cured. In a third case, where the patient was a man, aged 25 years, the same good resulted from treatment by curare. It appeared that with every day the patients lived the prognosis became better, the tetanus poison gradually losing its strength. If no natural sleep set in a hypnotic (chloral hydrate) was given at night. Nourishment (liquid) was administered, and if the sixth day of the outbreak had passed a hopeful prognosis could be entertained.

[1] Jacobi's Festschrift, 1900.

## THE METROPOLITAN WATER-SUPPLY.

THE interest of the monthly report of the water examiner to the Local Government Board is somewhat impaired by the fact that it is always a belated document (for example, the report for the month of June was published in August) and because the greater part of the information supplied is given by the metropolitan water companies. This arrangement, it is to be hoped, will be soon altered, but until the water examiner has facilities for furnishing a perfectly independent report all that can be done is to learn what we can from the available information. It is of interest to note that the average amount of water supplied per head per day was less in the case of each company during the month of June, 1900, than it was during the corresponding month of last year. The greatest reduction in the amount supplied obtained in the case of the Lambeth Company which effected a "saving" of nearly four and a half gallons per individual per day. The report shows that the companies have not yet generally carried out their statutory duties to give a constant water service to all their customers. The Chelsea Company and the Grand Junction Company, however, both profess to give a constant supply to the whole of their districts. In the case of the Lambeth Company three-quarters only of their supplies are constantly given. It would be interesting to know what steps the company are taking to carry out their duties in this respect and an inquiry by the Water Examiner into the matter appears to be indicated. In regard to the quality of the water supplied, Dr. Thorpe, the analyst to the Local Government Board, reported that the Lambeth Company and the Southwark and Vauxhall Company contained the highest proportion of organic carbon and that the water supplied by the Lambeth Company exhibited the "deepest average tint of brown." Improvements have lately been made, we may remark, in the arrangements of the Southwark and Vauxhall Company, but the Battersea filtering station is still in use and both the reservoir capacity and the filtration area of the company are below the standard of the West Middlesex Company, which is by no means too high. In the case of the Lambeth Company the reservoir capacity, judged by the same standard, is less

than one-third of what it should be. In these circumstances the "tint of brown" in the water supplied by the Lambeth Company is not a matter of surprise. The month of June was fine and the state of the untreated Thames water was good throughout. We may, perhaps, with advantage call the special attention of Dr. Thorpe to the state of the water supplied by the Lambeth Company during the periods when the Thames is in flood, to the water pumped from the Battersea station of the Southwark and Vauxhall Company, and to the water filtered at the Thames station of the East London Company. At present the analyses made by Dr. Thorpe are by no means numerous if we may judge from his report of July 6th. The examination of one specimen of the water of each company is hardly sufficient, for the quality of the water, for reasons which we need not specify, is likely to vary from day to day.

## A PRELIMINARY INVESTIGATION INTO THE PREVALENCE OF THE ANOPHELES MOSQUITO AND MALARIA IN CALCUTTA.

THE report of the health officer of Calcutta for 1899 contains, in addition to the record of facts and figures which are commonly forthcoming in official documents of the same character, some interesting information as to what is being done in Calcutta in regard to the part played by the mosquito in the transmission of malaria. Being convinced that mosquitoes of the anopheles type form a link in the transmission of malaria from man to man, although the exact nature of the connexion may not yet be fully understood, the health officer, Mr. J. N. Cook, thought that the time had come for seeing whether any reduction could be made in the fever returns of Calcutta by giving some practical effect to what have hitherto been more or less theoretical considerations. For that purpose he applied for and obtained permission to engage the services of natives who had been trained under Major Ronald Ross, I.M.S., to hunt for anopheles mosquitoes for the prosecution of his scientific work whilst in Calcutta. The object was to discover the places where these mosquitoes bred within the area of the municipality and if possible to kill them in the larval or pupal stage of their existence. The stipend granted to the natives (two of whom were in reality employed in the work) was too small and the time has been too short to allow of much being done; still what has been effected is interesting and instructive. The first thing, of course, was to ascertain the breeding grounds of the anopheles mosquito and this was done. The method pursued was simple and business-like. The natives hunted out and brought the specimens and indicated the places where they were obtained. Their observations were verified by the health officer and others who marked off the exact sites on a map. There were 89 such places discovered in the course of three months and the report furnishes a list of them. Most of them were tanks, but not large well-made tanks containing fairly clean water—for in such the anopheles larva are not found—but small ones containing dirty water and some low forms of vegetation corresponding to the duck-ponds of English villages. There is some reason to believe, by the way, that fish and tadpoles feed on the anopheles larva and reduce their numbers. The anopheles frequents the leeward rather than the windward side of a tank as a rule. The most favourable breeding grounds appear to be shallow ground excavations containing but little water. Some experiments were tried for the extermination of anopheles larva. It was found that they could be quickly killed in pools with kerosine oil, but reappeared again in about a week, so if they were confined to small pools and the breeding-places were not too numerous their extermination would not be a very difficult matter. Most of them could be killed off by kerosining the pools every few days, and the pools could be filled up or drained. The tanks, however, present much greater difficulties, as it is difficult to cover the surface of even a small tank that contains much vegetation with kerosine. Experiments in this direction were by no means a success. Much good would probably be effected by filling up or improving the foul tanks in which anopheles breed. It is doubtful whether tanks of the better class contain enough pabulum for their sustenance, for it must be remembered that the male mosquito is not a blood-sucker and has to obtain sufficient sustenance in the larval state to last him his lifetime. Another important point is that mosquitoes do not generally travel far from their breeding-places but remain under shelter when the wind is strong, so that once exterminated in any locality it is doubtful whether other mosquitoes would come in from outside to any extent. The observations and experiments may be so far regarded as only a preliminary investigation into the prevalence of anopheles, but they are of great medical and public interest.

## HOSPITALS AND LOCAL RATES.

IN our issue of March 10th (p. 715) we referred in our leading columns to the deputation which was received by the President of the Local Government Board concerning the exemption of hospitals and infirmaries from local rates. On May 22nd a select committee of the House of Commons was appointed to consider the matter and its report has just been issued as a Blue Book. We are glad to see that the committee consider that hospitals do relieve the rates and that institutions which minister to the sick poor have claims to exemption from rates at least equal to those which may be urged in favour of any foundation already exempt. The committee recommend that the principle of exemption from rates should be applied to all medical hospitals, infirmaries, or other institutions for the care and treatment of persons suffering from sickness or injury, or afflicted in mind or body, not carried on for profit or gain, and supported wholly or in part by voluntary contributions or endowments, and directly benefiting the rates in the county or district in which they are located to a greater extent than they pay rates. And they further recommend that any Bill introduced to give effect to this principle should confer power upon the rating authorities to deal with the question either wholly or in part, and that where the rating authority does not act under this provision such institutions may appeal to the county council, or such body as is the central rating authority, and that these bodies shall exempt such hospitals or hospital from rates, provided that they come within the above-named definition. We trust that the next session of Parliament may see legislation in accordance with the recommendations of the select committee.

## EPILEPTIC COLONY FOR CHESHIRE.

THE Lewis trustees are to be congratulated on the choice of an object on which to bestow some of the funds at their disposal. They have recently, we understand, purchased an estate near Warford, and here it is proposed to erect extensive buildings for the employment and treatment of epileptics. We do not yet know the particulars of the scheme, but we have no doubt that the trustees will have obtained all the most modern knowledge as to the best method of dealing industrially and medically with large numbers of epileptics. In this country we have much to learn from other nations, especially Germany and America, on this question, and the trustees, we doubt not, will avail themselves of the best continental experience. There is little doubt that there are in every large town a considerable number of epileptics both able and willing to work who

by their unfortunate infirmity are precluded from earning a living, and if these men and women can be reached and transformed into useful citizens a great work will have been accomplished. One thing the projectors of such an undertaking must understand—viz., that the institution should have a considerable endowment. Whatever it may accomplish in the course of years an industrial colony of the character apparently contemplated cannot in its early days be self-supporting. We cordially wish the initiators of this most promising scheme, who are at the same time the donors of the munificent gift, the greatest success in their generous and philanthropic enterprise.

## THE CONCILIATION BOARD.

AT the conference held at Manchester upon Medical Organisation at the beginning of May Dr. J. G. Glover announced that a meeting was about to be held between a committee of the British Medical Association and the committee of the General Medical Council (of which he, the speaker, was chairman) with reference to a conciliation board. The British Medical Association appointed a conciliation board, but the said board has not lasted long, for the council of the Association has just resolved "that the conciliation board be not re-appointed." The subject does not seem even to have been referred to the Association itself, the resolution being the work of the council. Either the General Medical Council must have been wrong in devoting so much time to the proposal or the council of the British Medical Association in devoting so little. Time will perhaps show where the fault lies.

## CONDITIONS PRODUCED BY THE BACILLUS AEROGENES CAPSULATUS.

THE *Boston Medical and Surgical Journal* of July 26th contains an important paper by Dr. Welch of the Johns Hopkins University on the pathogenetic rôle of the "bacillus aerogenes capsulatus," an organism first described by him in 1891. Dr. Welch has collected 46 cases of emphysematous gangrene in which the bacillus aerogenes capsulatus was found.[1] In the great majority of cases the bacillus was evidently introduced through a wound from without. Those injuries in which there was much laceration and crushing of tissue, comminution of bone, and grinding of dirt or foreign bodies into the tissues, such as compound fractures and bullet wounds, were the most likely to be followed by emphysematous gangrene. Severe traumatism, however, was not essential. In five cases the gangrene followed hypodermic injection and infusion of saline solutions. We have recently referred to cases of gaseous abscesses following hypodermic injections described at the Société Médicale des Hôpitaux of Paris and attributed to an organism termed by Veillon and Zuber the "bacillus perfringens."[2] This bacillus Dr. Welch believes to be identical with the one described by him. In three of Dr. Welch's collected cases (one of removal of the appendix vermiformis, one of strangulated hernia, and one of rupture of the rectum) the infection came from the intestine. The prognosis of emphysematous gangrene is now more favourable than in the pre-antiseptic period; in Dr. Welch's series the mortality was 59 per cent. But when the disease is accessible to surgical treatment, is not complicated by other grave conditions, and is promptly treated the prognosis is not unfavourable. Prophylaxis is obvious. The cases were treated by free incisions, by amputation, or by both. The results were better after amputations than after incisions. In certain uterine infections the gas bacillus has been found, and the occurrence of emphysema in the dead fœtus has been known for centuries. In 1897 Dobbin published a paper in the Bulletin of the Johns Hopkins Hospital on Puerperal Sepsis due to Infection with the Bacillus Aerogenes Capsulatus. During the life of the patient, gas and the gas bacillus were recognised in the fœtus, placenta, and cavity of the uterus; and after death there was general gas formation throughout the body. In another case in which the patient made a good recovery without sepsis, crepitation of the caput succedaneum was recognised while the fœtus was in utero. The bacillus is the chief cause of physometra, which was present in Dobbin's first case and is often associated with emphysema of the dead fœtus, but which may occur without it, and even in the non-pregnant uterus. Emphysema of the uterine wall is another and far graver result. Physometra is a necessary accompaniment unless the cervical canal is open and permits escape of the gas. The urinary tract may be not only a portal of entry of the gas bacillus into the circulation but also the seat of infection. In a case of urethral stricture with cystitis treated by perineal section gas bacilli were found three-quarters of an hour after death in large numbers in the bladder, ureters, and renal pelves, and a few bubbles and bacilli were present in the blood of the right ventricle. Gas may be found free in the bladder, ureter, or renal pelvis. The intestine is the commonest source of the gas bacillus, and invasion from it may result in the production of gas in the peritoneal cavity. Submucous and subserous gas cysts may also be formed. In the pleura the bacillus may give rise to pneumothorax without perforation.

[2] THE LANCET, April 7th, 1900, p. 1021.

## HOUSING OF THE WORKING CLASSES ACT, 1900.

THE Local Government Board has issued a digest of the provisions of the several parts of the Housing of the Working Classes Act, 1890, as amended by that somewhat meagre piece of legislation, the Housing of the Working Classes Act, 1900. The principal alterations effected by the latter are in respect of procedures under Part III. of the Act of 1890. This is the part which enables urban sanitary authorities with the sanction of the Local Government Board, and rural authorities with that of the county council, to purchase land and erect, or contract for the erection thereon, of "lodging-houses for the working-classes"—a phrase which includes "separate houses or cottages for the working-classes, whether containing one or several tenements." Part III. does not in any case come into force in a district until it has been adopted by the sanitary authority. The Act of 1900 makes adoption easier in rural districts by doing away with several of the obstacles created by the Act of 1890; moreover, in certain contingencies the county council will now have power themselves to adopt and enforce Part III. in any rural district in the county if they are satisfied that the district council concerned has been in default in "properly exercising their power of adopting and acting under" this part of the 1890 Act. In the event of land being purchased compulsorily, and in default of agreement, compensation is now to be settled by a single arbitrator appointed by the Local Government Board. Also it is made possible for district councils to lease land purchased by them under Part III. for the purpose of erection of working-class dwellings by private enterprise, subject to certain conditions being complied with. The new Act, it will be remembered, has now made it practicable for an urban authority to establish or acquire lodging-houses for the working-classes outside its district—a provision of great importance in the case of large towns. Whether these amendments will lead to more general use by sanitary authorities of their powers to provide working-class dwellings remains to be seen. At present no rural and very few urban districts have done anything in this direction. Lord Shaftesbury, some years after

he had been instrumental in obtaining three separate Acts relating to housing of the working classes, expressed in 1884 the opinion that there was no man living besides himself who knew of their existence. Now, however, public opinion is becoming more and more interested in the matter and there are many who, with some show of reason, regard existing legislation as giving inadequate opportunities of reform. But whether or not this is so cannot, after all, be satisfactorily determined until public health authorities in considerable number, both in urban and rural communities, have made serious effort to avail themselves of the considerable machinery which is at present at their command.

## GLASS IN THE STREETS.

THERE is one dangerous nuisance, specially annoying to cyclists but not without its serious aspects for other people and for animals, which should if possible be put a stop to—namely, the throwing of broken glass into the roadway. The quantity thrown out into the streets of our large cities is enormous. At a recent meeting of Manchester Cleansing Superintendents, Mr. Hamblett, of the Salford Cleansing Department, said that last year 97 tons of broken glass were taken from the refuse destructors and 224,742 unbroken bottles of various kinds. The *Manchester City News* estimates that the broken glass represents 650,000 bottles, worth about £3000 retail, and that the whole bottles would be worth another £1000. Children are said to be the chief offenders, but as shopkeepers and publicans generally require the deposit of 1*d*. per bottle the loss falls on the parents. The parents should, of course, teach their children better, but as the responsibility for their education and bringing up nowadays sits lightly on them perhaps the schools—board or voluntary—might come down occasionally from the "higher grades" to give some really useful lessons bearing on conduct. The same paper says that if the Salford average holds good for Manchester the bottle tax will be £10,000 a year and the glass would equal 2,200,000 bottles. Much broken glass gets carried with manure into gardens and fields, to the injury sometimes of the workers. What should be done with waste glass is a question, but if glass-works cannot re-melt it at a profit it might be sufficiently fused in the destructors to be rendered harmless and used in road-making.

## ACUTE POISONING BY TRIONAL.

DR. WARREN COLEMAN of New York records in the *Medical News* of July 28th, 1900, a rare and interesting case of acute poisoning by trional. The symptoms of poisoning by this drug have been said to consist of vertigo, loss of equilibration, ataxia, nausea and vomiting, diarrhœa, stertorous breathing and cyanosis, tinnitus aurium, hallucinations, and hæmatoporphyrinuria. The case recorded by Dr. Coleman is that of a woman, aged 35 years, who was suffering from a mild delirium brought on by an excessive indulgence in champagne and alcoholic drinks for several days. Six trional powders (of 15 grains each) were ordered to be taken, one every half hour for two hours. The patient became drowsy and sleepy and on the third day it was found difficult to rouse her. There were no disturbances of respiration or circulation to be detected by ordinary clinical examination. In answer to questions she replied that she was "dizzy and sleepy." Her speech was thick and she walked with difficulty, the gait being ataxic. She showed no sensory disturbances and the urine was free from hæmatoporphyrin. Upon inquiry it appeared that she had taken trional far in excess of the prescription and to the extent of nine drachms (540 grains) in 72 hours, the original prescription having been repeatedly made up at the stores. The patient was ordered a saline purge and she gradually recovered from her state of trional intoxication. The above case shows that trional is free from excessive depressing effects even when taken in maximal medicinal doses, and that even when by accident enormous doses are taken the result need not be necessarily fatal. The development of hæmatoporphyrinuria should always be looked upon as a danger-signal in cases of administration of trional or sulphonal, and the use of the drug should be discontinued until this symptom has passed away. Attention may be here recalled to a case of the sulphonal habit ending fatally which was recently recorded in these columns.[1]

## THE MEDICAL STAFF AND THE MANAGEMENT OF THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

WE publish in another column a correspondence between Sir James Crichton-Browne and Mr. B. Burford Rawlings, which sheds an interesting side-light upon the proceedings at the extraordinary general meeting of the governors and subscribers of the National Hospital for Paralysis and Epilepsy held on August 11th last. It appears that the extraordinary meeting was packed to this extent, that friends of the board of management received special notice of it which was not extended to friends of the medical staff. Can the people who thus divide the supporters of the hospital into two sharply defined classes be called friends of the hospital as a whole?

## SUBPHRENIC ABSCESS FOLLOWING APPENDICITIS.

IN the August number of the *Cleveland Journal of Medicine* Dr. J. F. Baldwin records two cases of subphrenic abscess following appendicitis. The first patient was a woman, 49 years of age, who suffered from appendicitis at intervals from 1894 to the end of 1898. In March, 1899, she complained of great pain and tenderness in the region of the appendix and along the ascending colon, with enlargement and tenderness of the liver, this enlargement being distinctly downwards. She lost considerable flesh and had constant elevation of temperature and pulse. On June 6th a greatly elongated and catarrhal appendix was removed. The right lobe of the liver could be easily palpated and was much enlarged; the enlargement seemed symmetrical and smooth, but owing to the patient's stoutness a thorough examination was not possible. Convalescence was satisfactory, but a little elevation of temperature persisted which could not be accounted for and the former pain and soreness recurred above the situation of the appendix. The liver was apparently greatly enlarged. There were no chills or sweats. On July 20th a chronic abscess was found pointing on the right side at about the tip of the twelfth rib, and when opened just below the twelfth rib it gave exit to an enormous amount of pus, leaving between the liver and the diaphragm a cavity the limits of which were beyond the reach of the fingers and which closed in about six weeks. The second patient was a female, aged 16 years, from whom a gangrenous and perforated appendix was removed on July 26th, 1899. A good recovery was made as regarded the operation, but from about August 10th she continued to have irregular fever, with rapid pulse and profuse perspirations. The liver became depressed below its proper position so that the lower border was some three fingers' breadth below the ribs. On August 28th an incision was made just below the border of the ribs and parallel with them. The liver was normal and a collection of pus of the size of a small orange was found between it and the

[1] THE LANCET, July 28th, 1900, p. 269.

diaphragm. Convalescence was prompt, the abscess and wound healing thoroughly in about two weeks. Dr. Baldwin has only been able to find records of 43 cases previous to his own, many of them having remained unrecognised until the necropsy. He says that the diagnosis must be based upon the continuance of the symptoms of infection after the removal of the appendix or after the subsidence of the inflammatory symptoms in the region of the appendix. There will also be some tenderness in the region of the liver, with a depression of its lower border owing to the accumulation of pus and exudate between its upper surface and the diaphragm. He recommends an infracostal incision made rather well back on the right side.

## LUNACY IN VICTORIA.

IN his annual report for 1899 Mr. J. V. McCreery, inspector of lunatic asylums in the colony of Victoria, states that the total number on the books of the asylums on Dec. 31st, 1899, was 4398, as against 4394 on Dec. 31st, 1898. The distribution of patients in the public lunatic asylums was as follows:—At Yarra Bend, 774; at Kew, 954; in the Kew Idiot Asylum, 231; at Ararat, 700; at Beechworth, 653; at Sunbury, 682; at Ballarat, 256; the remaining cases were either out on probation or boarded out. On page 13 of the report it is stated that the admissions during the year numbered 785 persons, 426 being males and 359 being females. This was the highest yearly number recorded since the asylums were opened. The general population of the colony at the end of the year was estimated at 1,180,878, and on this basis the ratio of the insane admitted during the year to the whole population would be 1 in 1504. In Victoria there was one lunatic in every 268 persons. Mr. McCreery considers that "there is strong reason to believe that a lesser percentage of our (i.e. the Victorian) population become insane now than 30 years ago." The patients discharged recovered were 352 in number, showing a percentage of recoveries of 44·44. The number of deaths was 348, the percentage of deaths on the average number resident being 8·27. The net weekly cost was 8*s.* 4*d.* Private asylums are not permitted in Victoria and Mr. McCreery recommends that the Lunacy Department should improve the existing accommodation for paying patients.

## HYSTERIA IN BOYS AND YOUTHS.

UNDER the above heading Dr. Arthur Hall of Sheffield gives in the August number of the *Quarterly Medical Journal* records of eight rather unusual cases, all of which had been diagnosed at some period or other as examples of organic nervous disease. One case was that of a boy, aged nine years, who walked with a staggering gait not unlike that of cerebellar disease. He could sit up in bed unsupported, but when he held his hands straight out in front of him there were some jerky movements as well as similar ones of the head and tongue. His walk was peculiar: when once set going he could walk in a fairly straight line, but directly he attempted to come to a standstill he reeled backwards with an inclination to one or the other side indiscriminately. He kept up this condition with great consistency until one day he was tired out and for a few moments he stood quite still. After this he staggered for some time badly, but a complete cure was effected by setting the magnetic interrupter of a faradaic battery in motion and warning him that it might have to be applied. Another case was also that of a boy, aged nine years, who was said to suffer from headache, squint, and diplopia. He alleged that he saw double anywhere within two feet of him, but not beyond that. Dr. Hall could not find any strabismus and had reason to doubt the diplopia, as although the boy saw two fingers when one was held up, yet when two were shown to him he said that he saw three. The symptoms all disappeared under treatment. Another case was that of a labourer, 21 years of age, whose symptoms simulated Jacksonian epilepsy. He had a somewhat unsteady gait and difficulty in coördinating his movements. While being questioned he complained of an attack of headache, then was suddenly seized with twitchings of the left arm and to a less extent of the left leg. He then gradually lost consciousness; his mouth and face also twitched. When he was examined in bed a large rounded pulsating swelling was felt on the left side of the head, under which the bone was absent, evidently a bulging of the cerebral membranes through an old trephine hole. After a few days Dr. Hall felt sure that the patient was shamming. The correctness of this view was proved by the patient on hearing it said that his case was one for an asylum or the police, recovering quickly and taking his discharge next day.

## THE SCHEDULING OF CARBOLIC ACID.

CARBOLIC acid is now a poison within the meaning of the Pharmacy Act, and in accordance with the provisions of the Privy Council Order it can only be sold by retail by registered persons. The vessel containing liquid preparations of carbolic acid above a minimum strength must now be distinctly labeled with the name of the article, with the word "poison," and with the name and address of the seller. The Order came into operation on Sept. 1st and the resolution of the council of the Pharmaceutical Society, in which carbolic acid was declared to be a poison within the meaning of the Pharmacy Act, 1868, was approved by the Privy Council on July 26th, 1900. There has, therefore, been some expedition exercised in getting this Order made law; and we are glad that this is so, considering the great number of lives that have been purposely as well as accidentally lost through the indiscriminate way in which the poison was hitherto sold in unrestricted quantity to the public. But the wording of the Order needs amendment. It states that "liquid preparations of carbolic acid and its homologues containing more than 3 per cent. of those substances" shall be deemed poison within the meaning of the Pharmacy Act, 1868, in accordance with the second part of Schedule A. Round the exact meaning of the word "homologues" much discussion is certain to turn, and, moreover, there are homologues of phenol which are non-poisonous. If we are not mistaken the word "homologues" will sooner or later have to be removed from the Order, and the precise substances which it is intended that the new Act shall include exactly specified.

## EPILEPTIFORM CEREBRAL DISTURBANCES ACCOMPANYING CONVALESCENCE FROM TYPHOID FEVER.

EPILEPTIFORM attacks during convalescence from typhoid and other acute fevers are decidedly uncommon. Professor F. Muhling of the German Hospital in Constantinople records in the *Münchener Medicinische Wochenschrift*, No. 7, 1900, an interesting phenomenon following typhoid fever in a patient, 23 years of age, a man of strong constitution, of good previous health, and with a good family history. In November, 1898, he became ill with typhoid fever, in the course of which he slept much and suffered from delirium at night. In the first week of the illness there was a sudden and marked fall of temperature the cause of which was not known. He gradually convalesced from the fever and on the twelfth day of convalescence, while in bed, he developed an epileptiform attack. The fingers of the left hand exhibited clonic spasms which then affected the left

eyelid and became generalised. The spasms lasted half an hour, during which time the pupils were widely dilated and did not react to light. After an interval of three hours there was a second attack which lasted 20 minutes, and five hours later there was a third attack lasting ten minutes. Both of these attacks had a course like the first. Six hours later a fourth and final attack supervened and this continued —with short intermissions lasting each from one to five minutes—for an hour. The patient was conscious and felt well between the epileptiform attacks, but after the last attack he suffered from symptoms of numbness and formication in the two outer fingers of the left hand. The urine was normal and there was no cardiac abnormality. The patient was put on bromides and made an uneventful recovery after this. The exact cause of the cerebral disturbances could not be traced, the question whether they were due to a small embolus or other cause of acute local cerebral anæmia being left open.

## THE PRESIDENTIAL ADDRESS AT THE BRITISH ASSOCIATION.

THE meetings of the British Association are a carnival of science. That is to say, we think that it may be taken without contradiction that the festival and the social side of science are more in evidence than the real work and toil of it. Excursions with an archæological or architectural substratum are much favoured, and were it not for these the meetings would probably be sparsely attended. This being so Sir William Turner is to be congratulated on the success of his bold attempt to lay before an audience composed in great part of men and women who take an intelligent interest in science without knowing very much about it an account of the processes of biology. But we fear that to many his account of the cell and its life, of karyokinesis and of cell cleavage, clearly expressed as it was, must have been somewhat unintelligible. Those who have watched the actual processes under the microscope will recognise how simply and plainly Sir William Turner, a master of his subject, has formulated the stages of karyokinesis; but to the average scientifically minded layman the terminology will seem as obscure as, for instance, an account of a bull fight with its references to the various feints and passes of the chulos and the matador is to the non-expert. We hope we do not wrong Sir William Turner's audience in believing him to have been above the heads of many of them. But if their technical knowledge enabled them to follow him we are sure that they must have been profoundly interested, for the study of the life processes in the cell is one of absorbing interest as a step on the journey towards that knowledge which at present seems unknowable. The evolution of the human race is perhaps the greatest problem with which we have to grapple and Sir William Turner well said: "Though from the nature of things the order of descent is, and without doubt will continue to be, ever a matter of speculation and not of demonstration, the study of the subject has been a valuable intellectual exercise and a powerful stimulant to research." When we consider how little we know we need not be downcast, for we can consider at the same time what enormous advances have been made in our exact knowledge even in the present century.

## THE ETIOLOGY OF "CANCER."

OF recent years many attempts have been made to discover the true cause of malignant growths, and one of the most valuable of these investigations was carried out by a committee appointed by the Birmingham and Midland Counties Branch of the British Medical Association. The committee was appointed in March, 1898, and their report was published in the *Birmingham Medical Review* in May, June, and July of this year. The investigation was limited to the counties of Warwick, Stafford, Salop, and Worcester, but it was found impracticable to obtain information with regard to every registration area. The committee drew up a circular mentioning the points on which information was desired and a schedule for tabulating the cases. The circular asked that the percentage of deaths from malignant disease in the whole district, and in each of the parishes comprised in it, might be ascertained, and that an accurate description should be given of the physical conditions of the districts where malignant disease appeared to be most prevalent. It was further requested that special attention should be paid to the situation and surroundings of any house or row of houses where malignant disease had occurred with marked frequency. Returns were obtained from more than 50 registration areas, with a population of more than 860,000, and 5300 cases of malignant disease were tabulated. The report deals at great length with the returns from every district, and these are of much value, but most interest will be felt in the conclusions at which the committee have arrived. The first point established by the returns is that there are certain areas in which the mortality from malignant disease is noticeably above, and others in which it is markedly below, 0·58 per 1000 per annum, the average for England and Wales. For instance, in the Shipston-on-Stour sub-district every parish except one has a mortality from "cancer" of over 1·15, while in the Foleshill registration area nearly every parish has a mortality from this cause below 0·47. The physical conditions which are found where "cancer" prevails are contamination of the soil with sewage and a general lack of drainage. There seems to be no definite connexion between the geological characters of the subsoil and the prevalence of "cancer." Evidence is also adduced that there is a special tendency to the occurrence of malignant disease in certain houses or groups of houses, and on the whole "cancer" is more common in old than in new houses and districts. The investigation has certainly accomplished all that could have been expected from it.

## CONSTIPATION FROM ATONY AS A FATAL DISEASE.

CONSTIPATION is one of the commonest ailments of civilised life and its relative frequency among people otherwise healthy leads us to regard it not so much as a disease but as the natural result of artificial conditions acting upon a healthy body. It may be due to either sluggishness of the peristaltic action of the intestines or to increased resistance to expulsion offered by the fæcal matters owing to hardness and dryness of fæcal masses. Mr. Robert Brummitt records a case of constipation as a fatal disease *per se* in the *Australasian Medical Gazette* for March, 1900. The story is very instructive and almost unique. The patient was a boy who since his birth in 1884 had suffered from chronic sluggishness of the bowels with constipation. Careful examination of the abdomen and of the rectum showed nothing abnormal save a few external hæmorrhoids. Every therapeutic means had been tried—unsuccessfully—to relieve his trouble. Laxatives and aperients, intestinal and general tonics, regulation of diet, massage, enemata of various kinds and irrigation, and faradaic electricity had been employed, but to no purpose. The relief occasionally obtained by a partial evacuation of the bowels aided by one of the above therapeutic means was only temporary. He continued to grow ill and to lose flesh, and eventually died in an emaciated condition at the age of 16 years, the immediate cause of death being peritonitis, his weight being only 60 lb. At the post-mortem examination it was found that the cæcum and the ascending and transverse colon were full of scybalous masses, which were

so hard that they could not be indented with the finger. Careful examination failed to disclose any constriction or obstruction in any part of the intestinal tract or any abnormality in its attachments to the abdominal and pelvic walls. "In the absence of marked organic lesions," says Mr. Brummitt, "I suppose this boy had congenital weakness of the intestinal walls probably due to defective innervation. This may have possibly conduced to abnormal dryness of fæces. He certainly had during the last few weeks fæcal obstruction and during the last few days peritonitis." If the causation was defective innervation of the intestinal walls, with consequent muscular atony, the various therapeutic means employed could give only temporary relief.

---

RECOVERY in a case of true generalised septic peritonitis is exceedingly rare. It is almost impossible to imagine that it ever occurs without treatment by an operation, and even when a laparotomy has been performed it can hardly be thought that it is possible by any amount of sponging or flushing to disinfect so large and irregular a cavity as the peritoneum. Yet cases are recorded. We publish one this week, which was under Mr. H. A. Duffett's care, in which practically the whole peritoneum was affected, and yet flushing was followed by recovery. A possible explanation of the successful issue in some at least of these cases is to be found in the variety of septic organism present; if this should be one of the less virulent forms the peritoneum is capable of dealing with it provided that the germ is not present in overwhelming numbers. Mr. Duffett is to be congratulated on his result.

---

A TELEGRAM from Earl Beauchamp, the Governor of New South Wales, to Mr. Chamberlain, received at the Colonial Office on August 29th, says, "I have to transmit subjoined bulletin of the incidence of the bubonic plague at Sydney up to August 25th, 1900—namely, remaining for treatment August 18th, seven; admitted during the week, none; discharged recovered during the week, four; died during the week, none; remaining for treatment, August 25th, three; total cases, 303; total deaths, 103; total discharged recovered, 197; total contacts isolated, 1707; total contacts remaining, none; total cases among contacts, seven; total Chinese attacked, ten; total deaths among Chinese patients, eight."

---

A REUTER'S telegram from Buenos Ayres on Sept. 3rd states that a case of plague has been notified there.

## THE WAR IN SOUTH AFRICA.

GREAT, and on the whole successful, progress has been made since we last wrote about the war in South Africa and the military situation has greatly improved. Officially speaking the war is ostensibly over, notwithstanding that the Boers may retreat to the hills and fastnesses of the Lydenburg district and give us much trouble by maintaining a mountain or guerilla warfare. So long as the Transvaal Government were able to pay for the munitions of war and the Boers had control of the railway from Machadodorp to Koomati Poort it would have been impossible to stop them from obtaining supplies, but the continuance of the war all depends now upon the quantities of these they have stored up. General Buller's division has been vigorously pressing in their pursuit, and he is at the time we write close to Lydenburg. The columns and divisions under the command of the other generals are also making a concerted movement and converging in pursuit of a definite strategical object. It has to be borne in mind, however, that General Buller appears to be in front of an almost impregnable position in the Lydenburg district at the present time and that the garrison of Ladybrand has been relieved only just in time. The general tenour of Lord Roberts's latest despatches would imply that much still remains to be done and that an army of occupation may expect to have a good deal of trying work before it.

The fever season in the low-lying malarious districts about Lydenburg will soon be setting in and much sickness from malarious fever may be expected to follow the occupation of the bush veldt hereabouts by the Boers; or by the British troops, on the other hand, if they have to invade and attack them there. The country and the nature of the fever may be said to resemble very closely those met with in the Peshawar valley at the same season. The facts of the Boers having released their British prisoners and having exhausted their Mauser ammunition show that they are hard pressed for food and munitions of war. The redoubtable De Wet is still at large. Our future difficulty will mainly be the old difficulty—namely, an insufficient supply of horses, for the maintenance of mounted troops will be necessary to counteract raids and capture the raiders. For the rest, Lord Roberts's proclamation of the annexation of the Transvaal by bringing home to the Boers and burghers that they will henceforth be regarded and treated as rebels may be expected to convince them that they have everything to lose and nothing to gain by further resistance.

So far for our prospects as regards the military and medical position. As for the political situation, we think it must be patent to all that the policy of the present Government in respect of this war has been greatly strengthened by the publication of the private and confidential correspondence captured at Pretoria. Mr. Chamberlain could have desired nothing better in order to justify and indicate his position in regard to this rebellion (for rebellion it was) of the Republican States in South Africa than the publication of these documents. The letters of Sir Henry de Villiers, who is by birth, family connexions, and association an Afrikander, which were written before the war, and those of Mr. Merriman, a political partisan of the Dutch, are strongly condemnatory of the course and policy pursued by President Kruger and President Steyn, while warning them at the same time as to what the consequences must inevitably be. To all those who have regarded the war as an unjust one or who had any conscientious misgivings and doubts about the part which this country felt compelled to take in it, a perusal of these letters—written prior to the war by men of character and judgment who were most friendly to the South African Republics—must, we imagine, tend to dissipate any doubts they may have entertained on the subject. Turning, however, to matters coming more strictly within the purview of medical journalists we may say that we have read a great deal in lay papers on the hospitals and the medical administration of the war in South Africa. The statements will be followed by others of an equally voluminous, conflicting, and unsatisfactory character so far as forming any guide to a useful judgment is concerned. The whole matter is, as we know, being investigated by a Royal Commission on the spot. Those who are, after all, in the best position to know the facts and to speak about them are the medical officers, their subordinates, and their patients, together with the headquarter staff and those who have taken part in the campaign. These are prohibited from writing to newspapers; and the large majority of them, at any rate, have not done so. We must, therefore, be content to wait and suspend our judgment until the truth or otherwise of the allegations has been thoroughly investigated—until the grain has been sifted from the chaff. For our own part, we are not only content to wait but are compelled to do so owing to the impossibility, as well as obvious unfairness, of adopting any other course.

Touching the course taken by Mr. Burdett-Cout M.P., we see no reason for altering or modifying the position which we originally assumed. Considering the great gravity of the statements made by him in his initial communication to the *Times*, the deplorable condition under which he described the sick and wounded in our army hospitals to be labouring, and all the anxiety and pain which such statements must inevitably cause to their relatives and friends, we consider that it was his paramount duty to have insisted upon seeing Lord Roberts in the first instance and to have personally represented the facts to him and to those of his immediate staff who either had the power to remedy the alleged evils or to afford them, if that

were impossible, an opportunity of explaining the circumstances and of saying how soon they would be remedied. If Mr. Burdett-Coutts had any practical suggestions to make he should first of all have put them forward in the proper quarters. Moreover, he should, in our opinion, have spared no pains to see whether he could have obtained the requisite aid and any supplies, of which he considered there was such urgent need, from some one or other of the various aid societies in South Africa. We also think that, even if he had made any effort in his power and failed, he might still have forwarded a written statement of the case to Lord Roberts and requested an interview with him or with the Chief of the Staff before having recourse to the press for the publication of his harrowing details. Mr. Burdett-Coutts must, at any rate, have known that a forced march had for very pressing military reasons been made, that the army had altogether outmarched its supplies, and that there was an exceptional strain on the army and the transport when the troops reached Bloemfontein, and he must have been acquainted with all the conditions which had preceded and followed the capture of that place.

It is to be proved how far the calamitous amount of sickness—from enteric fever, for example—should have been foreseen and could have been prevented, and whether, under the circumstances, any better hospital provision could have been made than was made, and if so who was responsible? That is what the Royal Commission have to determine. Even allowing for the sake of argument that there was any amount of negligence and want of foresight on the part of the medical staff, it must be admitted that much of what has appeared in the public press in the shape of correspondence and otherwise in regard to the state of the hospitals and the medical arrangements of the campaign generally is either unfounded, exaggerated, or irrelevant, the evident result of wounded vanity, or founded upon ignorance or ridiculous assumption. Although some of the productions, on the other hand, are written by those well qualified to give an opinion and contain criticisms which are deserving of every consideration, this is far from being the case with many of them. No impartial person, we think, who has read Sir Redvers Buller's emphatic and indignant protest against the accusations which have been brought against the officers of the Royal Army Medical Corps and the hospitals of the British army in Natal can have any doubt on that point. To read some of the letters in the press it would seem as if the members of the Royal Army Medical Corps were not all professionally qualified men, that they had not been educated at universities or medical schools or passed examining boards like the other members of the profession, and afterwards competed for appointment into the army. One person, for example, considers that having himself gone through a six months' course of medicine and surgical dressing in one London hospital, and been a patient for three months in another, he is qualified to give an opinion on the merits (or rather demerits) of those who have spent as many years as he has months in the study of their profession in order to qualify for the practice of it. He passes an unhesitating judgment as to the proper methods to be pursued in certain surgical procedures. His confidence is not so remarkably as the fact that he has got into print. There is no finality about anything in this world and we make no doubt that there is much which army medical officers themselves deem susceptible of improvement in their service, but a good deal of the present criticism is both unjust and unwise. If the Royal Commission can make any practical suggestions and recommendations for its improvement and the increase of its efficiency in war we can answer for it that the medical profession and the army medical service will be only too glad.

## SIR REDVERS BULLER AND THE OFFICERS OF THE ROYAL ARMY MEDICAL CORPS.

We have much gratification in calling attention to the emphatic testimony which Sir Redvers Buller has given to the work which the officers of the Royal Army Medical Corps serving under him have performed. It is well known that Sir Redvers Buller enjoys a reputation for out-spoken honesty and for having invariably the courage of his opinions. He has never hesitated to impute blame where he considers it to be deserved, and what lends additional weight and force to his opinion on this occasion is the fact that he was always opposed to having purely military titles conferred upon medical officers, as his letter to THE LANCET at the time this was done made manifest. We leave his trenchant remarks to speak for themselves in the subjoined letter addressed by him to the editor of the *Times*:—

SIR,—The *Times* of the 5th of July contains a letter from Mr. Lees Knowles forwarding extracts from the letter of a correspondent who is stated to desire his name to be private, but who, so long as he cannot be made responsible, has apparently no objection to his letter being used to give pain to others.

It is true that about six months ago the military hospitals in Maritzburg were attacked by a writer in the *Times of Natal*. It is also true that the author of those letters, having been induced to give particulars of his allegations, was confronted before a court of inquiry, presided over by Sir William Stokes, with each patient concerned, when every tangible accusation was proved to be groundless. But this is ancient history; how can stupid assertions discredited months ago "allay the anxiety of some of us who have friends out there"?

At the moment when the attention of England is directed to the hospitals at the Cape, Mr. Lees Knowles publishes, and endorses as the utterance of a person in high position, the following words:—"I am given to understand that the senior officers Royal Army Medical Corps, with few exceptions, are so taken up with their own importance as combatant officers, and their rank as colonels and majors, that they leave much to be desired."

Was ever a more shameful accusation more shamelessly published? There were then but three colonels Royal Army Medical Corps in Natal, outside Ladysmith. Colonel Gallwey, principal medical officer, has procured for the Natal Field Force the most complete hospital system ever provided for an army in the field. He is, I believe, the first P.M.O. who has ever provided nurses in the hospitals receiving wounded on the battlefield. His organising power and untiring energy, with assistance from home, added 4700 improvised beds to our hospital accommodation, and provided nurses, doctors, and attendants, some of them (let Mr. Knowles note) from Johannesburg. Colonel Clery was in charge of No. 4 General Hospital of 520 beds which was expanded into Mooi River Hospital of 920 beds; it was justly referred to by the writer of the articles in the *Times of Natal* as a model of what a hospital should be. Colonel Allin was senior medical officer of the field army and superintended the collection and subsequent removal of the wounded and sick from the front. I believe this duty has been accomplished by him more rapidly and with less discomfort to the sufferers than in any previous campaign.

I could say as much for the next senior officers R.A.M.C., but colonels are mentioned, and I challenge Mr. Lees Knowles and his correspondent of high position to say which colonels they refer to, and either prove their accusations or withdraw their slander.

I have the honour to be, Sir, your obedient servant,
Paardekop, Transvaal, August 4th. REDVERS BULLER, General.

Mr. Lees Knowles has since sent a letter to the *Times* of Sept. 5th in which, after explaining how he came to write the letter to which General Sir Redvers Buller refers, he continues: "Unfortunately, in extracts from my correspondence I included the sentence to which General Buller takes exception, and I wish now to withdraw it and at the same time to express my regret for its publication to those whom it may concern. I do so the more readily, because I am given to understand that it unwittingly casts reflection upon the work of the principal medical officer, whose acquaintance I made in Egypt in 1897–98 and for whose ability I had then, and I have now, the greatest admiration."

## THE IMPERIAL YEOMANRY HOSPITAL.

BY ALFRED D. FRIPP, M.S., F.R.C.S.

This is really little more now than a large convalescent camp. It is extraordinary what a tremendous change has come over the place since a fortnight ago when we were still very busy. We have had no death for two whole weeks and we have not taken in an ambulance train-load for three weeks. Very nearly 100 Yeomanry have been admitted during the week, but they are almost without exception convalescents from other hospitals. For instance, all the wounded, consisting of Warwicks, Gloucesters, and Lancashires, from the action nine weeks ago at Kheis have come on here from the Orange River Hospital. Just over 600 officers and men of the Yeomanry have passed through the hospital since it was opened. Of course, a very large number of Yeomanry have been laid up in other hospitals, it having been found impossible from one cause and another to have them sent here. There are many in the acute stages of illness whom it would not be safe to move; others are laid up in parts of the Free State almost inaccessible to proper hospital transport, but the facilities of collecting in this hospital all those Yeomanry who are in a fit condition to travel have been increased daily and the arrangements to that end are now, I believe, as nearly perfect as the complicated conditions permit. There is, for instance, a standing order at De Aar (which is the next station north of us and through which all patients going down country must pass) insuring that every train is warned to stop at Deelfontein and discharge any Yeomanry it may contain. Also, directly we hear that there are any Yeomanry in a hospital up country we telegraph to the commandant of that

hospital and ask him to send them to us as soon as they are fit to travel. But if we are right in supposing that the number of Yeomanry in South Africa is about 10,000 we have already had through our hands not less than 6 per cent. of them—a heavy proportion when it is considered that none of that limb of the service have been out here for more than five months. Out of the 600 already treated here there have been only four deaths, while out of the total number of admissions to the hospital (2575) there have been in all 59 deaths, a mortality of 2½ per cent., which is attributable almost entirely to enteric fever.

Since last week, when I think I mentioned that we had run out of tobacco, a very large quantity has arrived. Much of this has been contributed as presents by kind people at home. I want to take this opportunity of thanking all of our own personal friends who have shown us so much kindness in writing to us and in sending out so many gifts for the use of the patients. One most acceptable present was made by a lady who sent 548 eggs from England. We also owe our hearty thanks for 34 pounds of sweets from Buszard's, and for many pounds of chocolate, dozens of cases of sundry food preparations, and contributions of tobacco and pipes. I only wish the donors could see the immense amount of pleasure that they have given to the patients and also that they could appreciate the encouragement which it gives to the staff to have these perpetual reminders of the kind thoughts of friends at home. Everybody here is struck with the great liberality and thoughtfulness displayed throughout the war towards those who were fortunate enough to be able to come out, by those who, from one cause and another, were prevented from accompanying them. My impression, derived from pretty extensive acquaintance with the hospitals from Cape Town to Kroonstad and Mafeking, is that every hospital to which it has been possible to get the gifts transmitted has, owing to the work of the Red Cross Society and of allied institutions and to the generosity of the numberless private individuals who have contributed in some form or another, found itself abundantly supplied with such comforts and luxuries as tobacco, scent, scented soap, toilet vinegar, periodicals, books, warm underclothing, and knitted articles.

It really seems as if the fighting had nearly come to an end, but we are still anxiously waiting for the news of De Wet's downfall. The general impression out here is that it is only a point of honour which keeps Botha, who presumably is to be considered the commander-in-chief, from throwing up the sponge so long as one of his subordinates is in the field, but everywhere in South Africa one is behind you in England in regard to news. Except when a staff officer comes down to us from some part of the front and tells one the latest "in private" we have to wait for reliable information till the two days' old Cape Town papers reach us and even then the information has frequently been re-cabled from London.

The weather is once again perfectly magnificent and the health of the staff in general has very much improved since the work became lighter. I was very glad indeed to see that Dr. Conan Doyle had been calling attention in the London press to the arduous and dangerous nature of the work done, and done cheerfully, throughout this war by the hospital orderlies. Among all the brave deeds and hard work done by the various branches of the army during the last 10 months I do not believe that any body of men in Her Majesty's service has excelled, even if it has equalled, in bravery and pluck and continuous, even monotonous laboriousness, the behaviour of the thousands of men who have been employed in the hospitals. They have been called upon to do, in addition to a full day's work every day, a full night's work every fourth or third or even at times of stress every second night. Their work has gone on month after month quietly and unostentatiously without any of the glamour attaching to deeds which catch the public eye. Many of them have died at their work but very few indeed have grumbled. The service which they have rendered to their country has, indeed, in the fullest sense of the term, been splendid.

Several people have been asking what is to become of this hospital when the war is over. We have not yet heard that any decision has been arrived at, but, as I told you many weeks ago, my own hope is that it will be taken over as a going concern by the military authorities for the permanent use of the army of occupation, or, failing that, by the civil authorities, in which case it might be worked as a sanatorium with great advantage to the colony if not even to the empire. It is a most perfect site for a large hospital and its establishment is of such a substantial nature that without any but current expenses it could continue its useful work for many years. Every single thing that could be wanted (except, of course, consumable stores), even to the bacteriological laboratory which is essential nowadays to any such large institution, is to be found here in full working order.

We have had several visitors since I wrote last. The police magistrate of the district came with his mounted police for the purpose of raiding our native encampment. We had reason to believe that some natives were lodging there without employment in the hospital which alone gives them the right to remain near our camp. By surrounding the kraal with troops before daylight, and so preventing the escape of anyone, 14 intruders were found. Having arrested them Mr. Boyes proceeded to make a more systematic examination of the contents of each hut than we have ever been able to do, and the result was the recovery for the use of the hospital of a considerable quantity of blankets, china, buckets, and such like articles, and also the discovery of a lot of strong Kaffir beer, the presence of which near our camp had been known for some little time on account of the number of white men in our hospital who had succeeded in getting intoxicating liquors.

On the same day that Mr. Boyes was here Surgeon-Major Reade, R.A.M.C., and Surgeon-Major MacMunn of the Volunteer Medical Staff Corps, who have been detailed by Lord Roberts to go over and prepare the ground for the investigations of the Medical Inquiry Commission, the members of which will arrive in South Africa on August 21st, and also Colonel Lucas, R.A.M.C., Deputy Adjutant-General of the Yeomanry, and Colonel Deane, who have both just come out from England to make a tour for the purpose of collecting information bearing on the services rendered by the Yeomanry throughout the war, arrived as well. Surgeon-Major Kilkelly, R.A.M.C., Grenadier Guards, who as I told you in my last letter has been most fortunately secured to act as commandant of our branch hospital in Pretoria, was stopping here at the time on his way up from Cape Town, and with these six visitors I spent the whole day in making a complete tour of inspection of the hospital. They went very minutely into details and statistics and seemed very pleased with everything they saw, particularly with the sanitary arrangements and with the laundry and disinfector and destructor. Indeed, one trembles to think how fearfully the work of the hospital would have been hampered if the committee in London had not foreseen the need for the heavy and extensive plant with which, I am thankful to say, we are equipped. Surgeon-Major Kilkelly was so struck with the excellence of the arrangements displayed by Miss Brereton in the various departments under her charge that he asked for the loan of her services for the development of the new branch, so she and her friend Miss Leggett, who has been working under her, are going temporarily to Pretoria. With their experience of the essentials of a mixed civilian and military hospital, coupled with that of Dr. Barclay Black and Sergeant-Major Mackay, who went up to Pretoria with Colonel Sloggett and are remaining there, and with that of Surgeon-Major Kilkelly, who, as you know, has been acting since last autumn as commandant of the now disbanded Portland Hospital, the success of the new branch ought to be assured. There seems to be no doubt now that Pretoria will be its home.

I am glad to say that Colonel Sloggett, R.A.M.C., got back this morning. He was hung up for some days by a fresh cutting of the line, south of Kroonstad this time. Everybody is glad to have him back, but nobody is more glad than I am, for the military administrative work is very uncongenial to a civilian who is not trained to it, and there is so much of it that on the top of multifarious other duties it gives the uncomfortable feeling that one is trying to do too many things and is in consequence doing much work badly.

To-day is the August Bank Holiday, so we had an open-air concert in the afternoon at which there was a large and enthusiastic audience. Two or three of the farmers in the neighbourhood brought their families in and seemed to enjoy themselves very much. Whether it is intentional or not we are not sure, but it is not a rare thing for certain of these guests to get up and walk away before "God Save the Queen" is played. Others, however, seem markedly loyal. But loyal or disloyal they lose no opportunity of varying their monotonous lives by taking part in any

entertainments that are going on in our camp. I do not think that I ever told you that we are indebted to the ladies of the surrounding farms for having subscribed a fund for the purpose of putting a wall round our cemetery, whilst another colonial well-wisher has contributed young trees which are being planted among the graves.

There was quite a good Association football match here on Saturday between teams representing our orderlies and those of the Pretoria branch.

P.S.—Colonel Sloggett tells me that there is still no travelling north of Bloemfontein except during the daytime, that the line is being repeatedly cut almost daily by small commandos from 20 to 200 or 300 strong, and that in consequence there is a most fearful blockage of traffic, no fewer than 26 trains being at the present time kept waiting to go north at Bloemfontein. Food is therefore very scarce in Pretoria. There are very few sick and wounded in Pretoria now and so many nursing sisters that work cannot be found for all of them. He came down in No. 2 Hospital Train which has gone on to Cape Town but left three bad surgical cases here. At every hospital on the way down the authorities were anxious to take in this train-load, for there are many empty beds everywhere. No. 9 General Hospital, for instance, at Bloemfontein, which when I was there had 1800 patients in it, now has only 400. Colonel Sloggett says that the general impression is that all the heavy fighting is over, but that it will take some two months at least for the energies of those small flying commandos to be exhausted. Each man in Christian de Wet's reduced force is said to ride one horse and lead two others, and as he is thus moving extremely lightly without any wagons whatever he will presumably take a lot of catching even yet.

Deelfontein, August 6th, 1900.

A correspondent writes:—The photograph shows a convalescing soldier at No. 9 General Hospital, Bloemfontein, who was not posing for his portrait. The terrible condition of neglect in which he is plunged will strike the most casual observer.

## NOTES FROM BLOEMFONTEIN.

(FROM OUR SPECIAL CORRESPONDENT.)

The general health of Bloemfontein continues excellent and at the moment of writing there are less than 1200 patients in the three general hospitals, nearly all of whom are convalescents on their way down from the front. The weather continues superb, but the rainy season (September) is rapidly approaching, when the lot of those in the marquee hospitals will not be a pleasant one.

I paid a visit a few days ago to No. 9 General Hospital, mainly to see the surgical cases, as I had been informed of the arrival of a convoy of wounded in this hospital some days before. Lieutenant J. W. Smith, R.A.M.C., kindly showed me round the surgical division, of which he is in charge, and drew my attention in particular to some 120 patients suffering from bullet and shell wounds who had been recently admitted, all convalescent or doing well. There were only two cases of shell wounds, one in the neck and one in the shoulder; small fragments of shell had been found in both and the wounds were nearly healed. The bullet wounds were nearly all penetrating wounds of the extremities. The wounds from Mauser bullets had all healed well and nearly all without suppuration. I noted particularly the following three cases as presenting points of interest, the first two being useful object-lessons of the value of the very completely fitted up x-ray room attached to the hospital.

CASE 1.—The patient, a private in the Royal Irish Fusiliers, had a bullet wound of the left arm. The bullet, a Mauser, had entered the arm obliquely on the anterior aspect just above the elbow. About an inch above the humerus was thickened and tender. There was no wound of exit and careful examination revealed nothing in the rest of the limb. Lieutenant Smith at first naturally thought the bullet was imbedded in the humerus at the point where thickening was felt, but on taking an x-ray portrait it was found to be plainly visible in the axilla. On cutting down it was seen lying on the sheath of the axillary artery and parallel to the vessel.

CASE 2.—The patient was a private in the Munster Fusiliers. A bullet passed through the left groin, through the scrotum, and into the adductor region of the right thigh. It was discovered by the x-rays in the upper part of the popliteal space and was cut down upon and removed. The testicles were uninjured.

CASE 3.—The patient, a private in the Munster Fusiliers, was hit by a spent bullet in the deltoid region just below and behind the acromion. The bullet could be felt beneath the skin of the posterior fold of the axilla. On removing it it was found notched at the point and much grooved and twisted. What caused this it is difficult to say. In the first two cases the bullets were unaltered.

In both Case 2 and Case 3 the tracks down to the sites of the bullets were completely healed, but in each case the bullet itself lay in a rough-walled cavity containing about a teaspoonful of thin yellow pus-like fluid.

Dr. R. W. Dodgson from St. Mary's Hospital, the bacteriologist sent out by the War Office, has been busily engaged for some time in his laboratory at the Raadzaal and also visits the hospitals daily. He has taken notes of the course, symptoms, &c., of a large number of cases of enteric fever attacking both inoculated and uninoculated, but he is as yet cautious in giving a definite opinion as to the effect of preventive inoculation. He informs me that no less than 75 per cent. of the so-called "simple continued fevers" which he has examined—and he has examined a very large number—give the Widal typhoid reaction with serum; on the other hand, he has seen five cases diagnosed as "enteric fever" in which the characteristic serum reaction of Malta fever was obtained. Cases of "veldt fever" did not react to either test. These facts are very instructive, as in the opinion of most competent observers out here the official statistics give an absurdly high mortality from enteric fever compared with the real mortality owing to failure to diagnose mild cases.

I find a pretty general consensus of opinion amongst officers of the Royal Army Medical Corps and civilian surgeons that the War Office hospital marquee is on the whole superior to its rivals the Yeomanry marquee and the much-vaunted "tortoise tent." The Yeomanry marquee is an ideal one in calm weather but it is dangerous in high winds as the unyielding sides act as sails; the tortoise tent has the great advantages of being very portable and of taking up but little space when pitched, but with 10 beds, the usual number, it is apt to be very stuffy and in high winds it is not as safe as the War Office marquee. For economy in administration a much larger marquee than any in use would be desirable, and it is possible that eventually some form of tent resembling the "store tent" used by the Ordnance Corps may be adopted. This is a large marquee, 30 feet by 60 feet, with three upright poles and a ridge pole;

it accommodates 20 patients easily and leaves plenty of space for tables, chairs, &c. I understand that one of these tents has been fitted up as a ward in one of the general hospitals—I believe by Lieutenant-Colonel Keogh, R.A.M.C.—as an experiment; the results will be awaited with interest.

I have just returned from a flying trip to Springfontein on No. 5 ambulance train, for which I am indebted to the courtesy of Major M. T. Yarr, R.A.M.C., medical officer in charge of the train. I was glad to have again the opportunity of inspecting an ambulance train and of admiring the completeness of all the arrangements. These trains are really luxurious hospitals on wheels and have performed invaluable service throughout the campaign. At Springfontein we found the entire *personnel* of the Welsh Hospital, headed by Professor Hughes, on the point of entraining for Pretoria; all were in the best of spirits and looking forward eagerly to their new sphere of work. Since their arrival in South Africa they have done splendid work in their camp at Springfontein, but they were naturally anxious to get nearer the front. Springfontein stands about 5500 feet above sea level, 1000 feet higher than Bloemfontein. The climate is very tonic and bracing, but the frequent high winds and dust-storms occasion no small discomfort. No. 3 General Hospital is established there and has an excellent site close to the station.

Bloemfontein, August 6th.

## THE PLAGUE IN GLASGOW.

ON August 27th and 28th general currency was given to a disquieting report that cases of suspected plague had occurred in Glasgow. We made an announcement to that effect in THE LANCET of Sept. 1st (p. 716). At that date, there seemed to be no doubt, clinically and pathologically speaking, of the disease being plague, but the inoculation experiments were not completed. This confirmation of the clinical diagnosis was soon forthcoming, and the country was then made aware of the unwelcome fact that after an absence of more than 200 years the plague had once more obtained a certain amount of foothold in Great Britain. The circumstances of the two visitations, however, may be contrasted rather than compared. In the seventeenth century sanitary science could hardly be said to exist and the ravages of plague, small-pox, and "fever" were tacitly accepted as part of the ordinary course of events. At the present day, however, the origin and mode of propagation of epidemics are comparatively well understood, and the methods of controlling them have improved so much that there has been nothing of the nature of a serious loss of adult life from such causes in this country since the epidemics of cholera in the first 60 years of the present century and the epidemics of typhus fever and relapsing fever which accompanied the failure of the potato crops in Ireland in 1845 and 1846. The modern stumbling-block of epidemiologists is, in fact, constituted by diseases of infancy and childhood—scarlet fever, measles, and diphtheria—which although they receive but little attention from the general public nevertheless in the aggregate cause a great many deaths and too often inflict lasting damage on the health of those who survive the attacks. The large proportion of mild and untreated cases, which are nearly if not quite as capable of spreading the contagion as the most severe, and the long period of post-febrile infectiveness render these diseases almost ineradicable. The prevalence of enteric fever is well known to be a question mainly of excrement disposal, and in our towns and cities where the water-supply and sewerage are good its incidence is slight. Cholera is known to our populations only by name, because its spread has always been arrested at the moment of the discovery of the focus; and there is every reason to believe that modern sanitary methods will in like manner be able to localise the present outbreak of plague in Glasgow, especially as these methods are being employed with unsparing zeal by the medical officer of health of Glasgow, Dr. A. K. Chalmers. Through the courtesy of Dr. Chalmers we are enabled to furnish to our readers an account of the excellent precautions which have been taken under his supervision by the sanitary authorities.

That the disease could be arrested altogether or confined to the first cases recognised was too much to expect, for the cases with which the authorities are now dealing are not imported ones, but are examples of recent infection propagated from an unknown source and in an obscure manner, probably through the indiscriminate gatherings at two "wakes," one of which was held nearly a fortnight ago on the body of a dock-labourer's wife. Glasgow, of course, has a very large shipping trade with all parts of the world, and possesses docks and wharves extending for miles, so that the utmost vigilance on the part of the port medical authorities might fail to recognise a convalescent from plague brought in a steamer arriving from the Mediterranean or from Portugal. If the disease should unfortunately spread, some encouragement may be derived from the experience of the Australian colonies inhabited by a population of British origin and to a large extent living according to British usages. Plague made its appearance in New South Wales and Queensland in the early months of the present year, but has been confined to the cities of Brisbane and Sydney. In Sydney, with a population of 417,000, there were (as mentioned on p 775 of our present issue) 302 cases, with 101 deaths, up to July 28th, at which date there were practically no fresh cases. During the first six months of each of the six years 1894–99 the average notifications of enteric fever in Sydney were 435, so that the attack-rate of plague was less than that of enteric fever, although, of course, the death-rate was higher. These figures prove clearly that there need be no panic in Glasgow.

The first cases of bubonic plague which came under medical observation in Glasgow were visited at their home at 57, Thistle-street on August 24th and were removed on the following day to the City Hospital for Infectious Diseases at Belvidere, where the disease was immediately suspected to be plague. We publish below Dr. J. Brownlee's and Dr. J. C. McClure's excellent account of the clinical aspect of the two cases upon whose symptoms the diagnosis of plague was founded. Our readers will be able to appreciate from these accounts the thorough nature of the way in which the disease was grappled with at its onset. No time was lost, no precaution spared. We also publish below from Dr. Thomas Colvin, who was early called to the cases, a preliminary note upon them. With great clearness he details the symptoms and environment of the sufferers and points out the difficulty of diagnosis. To the fact that Dr. Colvin, while hesitating to give a name to the condition, clearly recognised that he was dealing with a highly infectious malady, Glasgow may probably owe a debt of untold greatness. The provisional diagnosis of plague was soon confirmed by inoculation experiments. On August 31st there was a meeting of the magistrates' committee and the health committee of the corporation, at which the medical officer of health recommended that a considerable area surrounding Thistle-street should be deemed infected. He therefore reported that plague existed in the district bounded by Cumberland-street on the south, South Wellington-street on the east, Adelphi-street and Carlton-place on the north, and Bridge-street and Eglinton-street on the west, and that it would be desirable to use special sanitary measures in order to prevent the spread of the disease. The magistrates' committee having considered the report approved thereof and remitted to the medical officer of health powers to forthwith enforce the provisions of section 254 of the Glasgow Police Act, 1866, within the said district. The medical officer of health further proposed that the following measures be immediately taken. 1. (*a*) That in each "land" from which a case is removed the lobbies, staircases, common passages, and each house be disinfected and cleansed by the sanitary department, the cleansing department making special arrangements for emptying and cleansing ashpits and hosing out courts; (*b*) that tenements from which "contacts" are removed be dealt with similarly to the foregoing. 2. That the district above defined be constituted a special cleansing area, the provisions to include a thrice-weekly emptying of ashpits, limewashing thereof, hosing of courts, special removal of rubbish, &c. 3. That medical inspection of the district be organised and carried out by the medical staff of the sanitary department, with the addition of two duly qualified and suitably experienced medical practitioners,

and that inoculation with anti-plague serum be offered free of charge where deemed advisable. 4. That a special sanitary inspection for dirty stairs and houses and for overcrowding of houses be instituted. 5. That rat-catchers be employed for service where deemed necessary within the said district. 6. That a handbill be posted within the district directing the attention of the public to the fact that immediate medical attention may be had from the sanitary department on communicating therewith through the nearest police office or station. The committees approved of the foregoing proposals and directed the sanitary inspector, the superintendent of cleansing, the chief constable, and all other officials interested to act in constant coöperation with the medical officer of health in fully and effectually carrying out the said proposals and safeguarding the public health.

The medical staff of the health department was at once increased by the appointments of Dr. Frederick Dittmar and Dr. Alfred Webster who have had experience of infectious diseases in Belvidere Hospital and who now have the duty of examining all infectious and suspected cases in the above-mentioned plague-infected area. Every infected house has been denuded of its clothing and bedding, the furniture has been thoroughly fumigated with sulphurous acid, the walls and ceilings have been whitewashed, the floors and woodwork have been washed with carbolic acid solution, wearing apparel has been treated with a solution of corrosive sublimate, and all beds have been either treated in the steam disinfector or else destroyed. Staircases, landings, and lobbies leading to infected houses have been whitewashed. All the wet ashpits and privies of the city have been limewashed. Two reception houses are in use, one in Provan-place, North Montrose-street, and the other in Weaver-street. In these two houses by Sept. 5th 111 persons had been kept under observation, of whom several were attacked by plague. It is intended that those in whom no symptoms make their appearance shall be liberated after 12 days' detention. On Sept. 5th there were in the Belvidere Hospital 13 cases of plague.

A disconcerting circumstance is the discovery of an undoubted case in the adjoining burgh of Govan situated on the south side of the river Clyde immediately below Glasgow. This patient was a boy, nine years of age, who resided with his parents at 684, Govan-road, nearly two miles from Thistle-street. Early on August 29th he was seized with headache and vomiting and on August 31st he died suddenly. It is not known how the disease may have been contracted, but, as Dr. Colvin points out very clearly in his statement, there were several days during which the first patients were visited by promiscuous acquaintances. Yersin's anti-plague serum has been obtained from the Pasteur Institute in Paris and on Sept. 3rd the medical men and nurses in attendance on cases of plague at Belvidere Hospital were inoculated with it.

Attention may here be called to a remarkable paragraph in the letter of our Berlin correspondent published on p. 778 of our present issue. He states that some days before plague was discovered at Glasgow a German newspaper (which he does not name but which was, perhaps, the *Berliner Lokal-Anzeiger*) stated that it was believed at the German Imperial Health Office that Cardiff and some other British ports were infected with plague. We are not surprised that such belief should be rife, for our less responsible press do their best, it would seem, to give such impressions to our continental neighbours. We should much like to know where the circumstantial story of an outbreak of plague at the Albert Docks, which was widely circulated at the beginning of the week, had its malignant origin.

---

## A STATEMENT FROM THE MEDICAL OFFICER OF HEALTH OF GLASGOW.

Dr. A. K. Chalmers, medical officer of health of Glasgow, sends us the following statement with regard to the circumstances, so far as at present they are known, attending the existence of cases of plague in Glasgow:—

A child and its grandmother Mrs. B——, living in the same house at 71, Rose-street, South Side, Glasgow, sickened suddenly on the evening of August 3rd, the child dying on the 7th and the grandmother on the 9th, the cause of death of the child being certified as "zymotic enteritis" and of the grandmother "acute gastro-enteritis." In both cases a wake was held. The grandmother was buried on the 11th. Although the husband of this latter patient sickened on the 12th he was only admitted to hospital on Monday, August 27th, certified "enteric fever," when he was recognised to be suffering from plague.

Concurrently with the later developments in this household the following illnesses were appearing in the members of a family living in 57, Thistle-street, some of whom had either attended Mrs. B——'s wake or were present during the illnesses in her house. On the evening of Sunday, August 19th, a child, Christina M——, 10 years, sickened with acute symptoms which ended fatally at mid-day on the 21st. She was only medically visited, however, within 10 minutes of her death. The symptoms were those of pneumonia and the cause of death was certified as "acute pneumonia." Before the child died the mother had already sickened (on the 20th); a son (since dead) sickened on the 22nd; and a half brother, a young child of three years, sickened on the 23rd. These three were first seen by Dr. Robertson, who had also seen the child Christina, and later by Dr. T. Colvin who, on discovering that Dr. Robertson had already visited the patients, went to confer with him regarding the symptoms. The action in which this conversation ended is thus described by Dr. Robertson:—

> We were satisfied that they were cases demanding the attention of the sanitary authorities, and I agreed with Dr. Colvin that, having both seen them independently, we should both notify them as cases of enteric fever, with a mark of interrogation after it, to imply that the diagnosis was not definite, but that they were evidently of an infectious nature, and should be removed at once.

On August 25th they were accordingly notified and the patients were removed to the hospital on the same day.

On admission Dr. J. Brownlee, the physician superintendent of the Belvidere Hospital, made a careful examination of the cases which resulted in his coming to the conclusion that the patients were suffering from bubonic plague, although they were inhabitants of Glasgow and there was no known case of bubonic plague in Britain. Dr. Weir, senior assistant physician at the hospital, and Dr. Knight, my assistant, concurred in the diagnosis. Dr. McClure, acting superintendent of the Small-pox Hospital, immediately examined blood-films obtained by hypodermic puncture of the buboes, with the result that the typical forms of the bacillus pestis were observed. Immediately on this conclusion being arrived at Dr. Knight visited the patient's house, verified the story of the illnesses and death, and arranged for the removal of the other members of the family to the reception house for observation. Cultures taken on glycerine agar showed by the evening of the 26th and the morning of the 27th the typical appearances both macroscopical and microscopical of the bacillus pestis. Later in the week they were fully confirmed by animal experiments by Dr. R. Muir, professor of pathology in the University of Glasgow, in the absence of our own bacteriologist, Dr. R. M. Buchanan. On the same day that these three cases were admitted (August 25th) another woman, Mrs. T——, living at 23, Oxford-lane, had been admitted, her disease being certified as typhus fever. This disease was excluded on examination, and owing to the presence of an inflammatory condition in the left groin and a history of recent confinement the provisional diagnosis of pelvic cellulitis was entertained. Later her association with the B—— family was discovered and the diagnosis revised in the light of the symptoms presented by these others.

Immediately the suspicion of plague was created a medical examination was made of all persons who could be discovered as having attended either the B—— wake, or the wake of the child M ——, with the following result:—

A.—Discovered ill in their own houses.

1. Two children, sons of Mrs. T——, already referred to. One of them is not suffering with plague.

2. A girl named McK——, residing at 57, Thistle-street.

B.—Removed to reception house. Fully 100 persons who were not obviously ill, but had visited one or other of the houses named, were removed to the reception house for observation and three of them have since sickened (M——, McG——, and D——).

Two further cases (F——, 77, Rose-street, and C——, 1, Well-street, Calton) were afterwards brought under notice of the department by medical practitioners, presenting symptoms of plague and after examination removed to hospital. C—— has an indirect connexion in respect of having slept in a house next door to that of the B—— family on August 15th, and F—— is a jobbing shoemaker living in the adjoining tenement.

By Sept. 2nd 14 cases had been placed in hospital, one had died, and of those then remaining 12 present the clinical

SUMMARY OF CASES WITH DATES OF SICKENING AND EXPOSURE AS FAR AS THEY ARE KNOWN.

*Deaths at Home assumed to be Due to Plague.*

| Name. | Age. | Address. | Sickened. | Died. | Remarks. |
|---|---|---|---|---|---|
| (1) Baby in B. family | — | 71, Rose-street. | August 3rd. | August 7th. | — |
| (2) Mrs. B. ... ... ... | — | ,, | ,, 3rd. | ,, 9th. | Wake held August 9th and 10th. |
| (3) Christina M.* ... | 10 | 57, Thistle street. | ,, 19th. | ,, 21st. | ,, ,, 21st and 22nd. |

* Attended the B—— wake.

*Cases Removed from their Homes.*

| Name. | Age. | Address. | Sickened. | Removed to hospital. | Where exposed to infection. |
|---|---|---|---|---|---|
| B (1) James B. ... | 60 | 71, Rose-street. | August 12th | August 27th | Wife died August 9th (see above). |
| B (2) Pat F. ... | 56 | 77, ,, | ,, 13th | ,, 29th | A jobbing shoemaker living near B——'s, but definite contact not traced. |
| B (3) John C. ... | 24 | 1, Well-street, Calton. | ,, 17th | ,, 30th | Slept in house adjoining B——'s on August 13th. |
| B (4) Mrs. T ... | — | 23, Oxford-lane. | ,, 12th | ,, 25th | Relations and visitors at B——'s. |
| (5) James T.† ... | 9 | ,, | ,, 21st | ,, 29th | |
| (6) Dennis T. ... | 6 | ,, | ,, 21st | ,, 29th | — |
| B (7) Mrs. M. ... | — | 57, Thistle-street. | ,, 20th | ,, 25th | Attended B——'s wake. Child died at home on August 21st (see above). |
| B (8) Pat. M. ... | 21 | ,, | ,, 22nd | ,, 25th | Pat C. M. died in hospital on August 27th. |
| (9) Wm. M. ... | 3 | ,, | ,, 23rd | ,, 25th | — |
| (10) Annie McK. | 12 | ,, | ,, 28th | ,, 29th | At B——'s wake and afterwards in house. |
| B (11) Thomas H. | 14 | 6, South Coburg-street | ,, 23rd | ,, 29th | At M——'s on August 20th. |

B. Bacillus obtained. † James has not plague but a gluteal abscess.

Four cases occurred among contacts who sickened in the Reception House—viz., Jane M., Arch. D., Pat. McG., and Angus R. Two sickened on August 29th and two on August 31st. All four were at the M.'s wake. These bring the total of cases to 13, excluding James T——.

symptoms of plague. In eight the diagnosis was microscopically verified; and in one the diagnosis remained doubtful for a time, but plague is now excluded. Since that date four other persons who had been in contact with affected persons were admitted on suspicion. In two the diagnosis later definitely excluded plague, in one the condition is regarded as pestis minor and in one the diagnosis still remains doubtful.

At the present moment it is impossible to make any definite statement as to the source of the infection of the first two cases in the B—— family. The husband of the elder patient was in the service of a local shipping company as a dock-labourer, and employed by them at their wharves on the south side of the river. He was engaged exclusively on vessels trading between home ports. His illness only developed after his wife died, and may be regarded as resulting from this or from his grandchild's illness. His daughter, the mother of the child who first died, is said by her father to have been ill for two days shortly before her child sickened. She now displays, one month afterwards, very slight enlargement of the cervical and axillary glands on both sides, which compared with the glands of a normal girl—definitely non-infected—of corresponding age indicate some irritative process recently active. This girl meanwhile stoutly denies any illness, and it must be remembered that she had nursed her baby for some time. The father of the child is an ironworker in constant employment. He has had no illness and presents no evidence of glandular enlargement.

### CLINICAL ASPECTS OF CASES OF PLAGUE UNDER TREATMENT.

Dr. John Brownlee, physician superintendent of the City of Glasgow Small-pox Hospital, and Dr. J. Campbell McClure, M.B., acting superintendent, send us the following interesting account of the clinical aspects of the cases of plague now under treatment in the City of Glasgow Fever Hospital, Belvidere:—

The patients admitted to this hospital suffering from plague may be divided into three classes: (1) those who had solitary bubo; (2) those who had the more generalised form of the disease where several groups of glands were involved; and (3) those very mild infections which it would be quite impossible to recognise apart from the history of infection. Yet these cases undoubtedly correspond to those cases of sore-throat which represent the mildest form of scarlatinal infection, or to those cases of slight febricula noticed among children who have been exposed to the infection of typhus where the fever aborts prior to the appearance of the eruption, and where association affords the only certain means of forming an opinion.

All the cases, however, have had certain groups of symptoms in common. The initial symptoms of headache and general malaise with nausea and vomiting have occurred with remarkable uniformity, even although the fever might be very slight. Following on these there was an almost uniform complaint of pain in some one or another group of the lymphatic glands. As far as observations have as yet gone the *facies* of all the patients has been characteristic. In severe cases, and in the earlier stages of even the milder cases, the expression of the face has been dull and yet apprehensive, the degree of stupor depending upon the gravity of the illness. In the milder cases the patients have looked ill out of all proportion to the amount of fever present and the degree of enlargement of the lymphatic glands, and have retained the peculiar *facies* for some days after all constitutional symptoms have disappeared. The buboes have exhibited all degrees of severity from the single slightly enlarged gland of the abortive type of the fever, through the fairly large and very tender buboes of the generalised type with or without reddening and œdema of the skin, to the large and intensely inflamed mass of glands seen in the cases of solitary bubo, where the redness of the skin and the œdema of the neighbouring tissues might extend to about nine inches or even more from the centre of the disturbance. The duration of the fever has varied from the slight febricula of the abortive type where the temperature may not have exceeded 100° F. to the severe fever of the generalised and true bubonic types. In the latter the fever has run a course resembling that of the better known typhus and enteric fevers. Crisis has been present in all our severe cases and it has occurred from the twelfth to the twentieth day. The tongue has been a very marked feature of the illness, for except in the two most protracted cases where the fever has run a course of about 20 days there was no tendency to dryness. It has been usually moist, covered on the dorsum with a greyish fur, and with the edges clean and red.

We record the clinical features of the two cases on which the diagnosis was originally based:—

(1) Patrick Malloy, aged 21 years, 47, Thistle-street, Glasgow, was admitted on August 25th to the hospital, his case being certified as "enteric (?)."

*History.*—Patient has been living in the same room as his sister, who sickened on August 19th, and died on the 21st, of what was presumably plague. There is no other known source of infection. The incubation period is, therefore, probably under four days. As the patient is not in a condition to give an account of himself the information was obtained from his mother who volunteered the following history. Until three days prior to admission the patient appeared in his normal state of health. On that date (August 22nd) he suddenly experienced a shivering associated with sickness, vomiting, diarrhœa, and pain in the abdomen. During the night the patient was evidently delirious, and delirium has been a notable feature of his illness until the time of admission. With the exception of measles and whooping-cough patient has suffered from no other infectious disease.

*Condition on admission.*—On admission the patient looked extremely ill. He was clearly in a state of semi-coma. The face generally was of a greyish colour with a more marked circum-oral pallor. In spite of the stupor in which the patient lay the expression of the face was distinctly anxious; there was marked knitting of the eyebrows, the eyes were widely open, and the conjunctivæ were slightly congested. The respirations were slow, numbering 18 per minute, and sighing. The skin generally was hot and dry. It was covered with a faint purplish mottling most marked across the lower part of the abdomen, the arms, and the buttocks. The characters of this eruption somewhat resembled the skin conditions of typhus fever. The tongue was moist and covered in the centre with a thick greyish fur while the edges were clean and red. There was no congestion of the fauces. There was in the upper part of the deep cervical chain a swelling composed of one moderately enlarged and several slightly enlarged lymphatic glands. The tissues surrounding these were markedly infiltrated and the skin was reddened and œdematous. Manipulation of this swelling was evidently very painful. There was no enlargement of glands in the right cervical region or of the superficial chain on the left side. The right axilla was filled with a large mass evidently composed of lymphatic glands embedded in œdematous cellular tissue. Here, again, the skin was red and œdematous and movement of the arm or even the lightest palpation gave rise to exquisite pain evidenced by the wincing of the patient even in his semi-comatose condition. In the left axilla a few glands were slightly enlarged but not tender. No enlargement of glands was apparent in either groin. The temperature was 103·6, the pulse was very soft and easily compressible and numbered 128 per minute. The lungs revealed nothing noteworthy on physical examination. The cardiac sounds were pure; the first sound was rather weak. The abdomen was not distended and was neither painful nor tender. There was no apparent enlargement of either liver or spleen. Exploratory puncture of the glands of the axilla was performed and an immediate examination of films prepared from the blood withdrawn revealed the presence of a considerable number of bacilli morphologically identical with the bacillus pestis of Kitasato.

*On August 26th* the general condition of the patient remained much the same, though the respirations were more rapid, numbering 28 per minute, but the local conditions had undergone marked alteration. In particular the lymphatic glands on the left side of the neck before mentioned were much more enlarged and the superficial glands on that side were now considerably involved. Late in the afternoon the glands in the left groin were easily palpable and slightly tender. The œdema in the right axilla was more extensive, involving the anterior border. The spleen was found to be enlarged to percussion though not palpable below the costal margin. The temperature at 6 A.M. was 102·4° and at 6 P.M. 104·4°. The pulse in the morning was 112 and in the evening 132 and even softer than on the previous day. On this evening the glycerine-agar cultures made after puncture of the glands on the 25th and incubated for 24 hours at 37° C. were examined. There was a faint surface growth composed of minute whitish translucent colonies. Cover-glass preparations were made from this growth and stained with an aqueous solution of gentian violet. These showed the presence in pure culture of a short bacillus with rounded ends, tending to run in pairs and showing well-marked bipolar staining. The bacillus was decolourised by Gram's method. The character of the culture and the morphological appearances of the bacillus and its staining reactions confirmed the diagnosis made from the examination of the films on the 25th that the organism under consideration was the bacillus pestis.

*On August 27th* the local conditions had if anything advanced, but the general condition of the patient was rather better. There was a little less mental obtuseness though it was still with great difficulty that he could be got to show his tongue. This improvement, however, was not maintained. By mid-day the patient was cyanosed and the pulse was notably weaker. He sank rapidly and died at 3.35 P.M.

*Report by Professor Muir on the Post-mortem Examination of Patrick Malloy.*

The body of the deceased is that of a fairly well-nourished though rather slightly-built man. There is a distinct swelling in the right axilla and also a well-marked swelling in the left side of the neck. In the left groin there is a fairly distinct swelling and also a very slight one in the right groin. Well-marked hypostasis and diffuse congestion exists in the region of the neck.

*Thorax.*—The pericardium contains about half an ounce of blood-stained serum. The right side of the heart is greatly distended with dark-coloured partially clotted blood, while the left side is rather contracted and empty. The cavities are of normal size and the valves appear healthy. The heart muscle is rather paler than normal, but not specially soft. Over the apex of the left lung are a few old adhesions. There is no fluid in the pleural cavity. The lungs show marked hypostatic congestion and also some collapse but no pneumonia. The glands at the root are not affected. The bronchi contain some purulent mucus. The right lung is adherent all over especially over the lower lobe. There is an old cicatrix on the chest wall over this part (resection of rib?). This lung is otherwise in a practically similar condition to the other.

*Abdomen.*—The peritoneum is normal. The spleen is enlarged, weighing 12½ ounces, the increase being chiefly in breadth. The consistence is softer than normal but by no means diffluent. The pulp presents a pale and mottled appearance and the Malpighian bodies are small and distinct. The liver is somewhat swollen, pale, and soft, and evidently the seat of cloudy swelling in a marked degree. Both kidneys are somewhat swollen and soft owing to cloudy swelling of the cortex. No hæmorrhages exist. The pancreas is slightly swollen and softer than the normal. The suprarenal bodies are rather swollen and softened

*Lymphatic glands.*—The glands in both groins show enlargement especially in the vertical group along the vessels. They are somewhat irregular on the surface, extremely tense, much congested, and show small hæmorrhagic points. The substance is rather softer than normal and there is no evidence of suppuration. The enlargement also affects the glands along the inguinal vessels and some of them are distinctly hæmorrhagic. The retro-peritoneal glands along the aorta show great swelling but none of them reach great size. In the right axilla there is a large swelling almost as large as a closed fist composed of a mass of enlarged glands bound together by infiltrated tissue. The largest single glands are about the size of a small plum. They are of a dark red colour owing to the diffuse hæmorrhages into the substance and here and there show partial softening. The periglandular tissue is the seat of a gelatinous œdema with diffuse hæmorrhages. The involvement of the glands extends upwards behind the clavicle. On the right side there is great enlargement of the cervical glands below the sterno-mastoid muscle, where there is a large irregular mass. The amount of hæmorrhage is extreme, some of the glands presenting a deep crimson colour and being also much softened. Here, also, there is much inflammatory infiltration. The glands in the upper mediastinum are also enlarged and surrounded by inflammatory œdema. A scraping from one of the inguinal glands shows enormous quantities of the bacillus pestis.

The examination of cultures made at the time on glycerine agar by Dr. McClure showed pure cultures of the bacillus pestis from the liver, the kidneys, and the lymphatic glands, while from the spleen a mixed culture of bacillus pestis and bacillus coli communis was obtained.

(2) Mrs. Malloy, aged 40 years, of 57, Thistle-street,

Glasgow. Admitted August 25th to the hospital, the case being certified as "enteric (?)."

*History.*—The patient on the night of August 10th was at the wake of a Mrs. Bogan, who died of what was presumably plague. There is no other known source of infection. The incubation period is, therefore, presumably ten days in this case. On admission the patient stated that she was first taken ill on August 20th with shivering, vomiting, severe headache, diarrhœa, and slight pain in the abdomen. Next day she felt uneasiness in the right groin, and on examination she found a small swelling which was very tender. The general symptoms became more urgent and the swelling in the right groin increased rapidly in size and in tenderness. During the whole of her illness she was confined to her bed.

*Condition on admission.*—The patient was quite intelligent but looked very ill. The face was slightly flushed and wore a rather anxious expression. The pupils were moderately dilated but there was no injection of the conjunctivæ. The tongue was moist and only slightly coated in the centre with a whitish fur. The skin was hot and dry and no eruption was noticed on any part of its surface. In the right groin there was a mass evidently composed of enlarged lymphatic glands surrounded by inflammatory tissue to the extent of obliterating the fold of the groin. The skin over the mass and for a considerable area around about, particularly laterally, was deeply reddened and œdematous. Over this area the tenderness was extreme, much exceeding that usually elicited in ordinary infective buboes. At the upper border of the swelling deep palpation showed that numerous glands in the deep group of lymphatics were also enlarged and tender, but there was practically no infiltration of the cellular tissue of this region. The skin over the right iliac region was normal in appearance. The glands in the left groin and in the axillary and cervical regions were not palpable. Nothing noteworthy was discovered in the heart or in the lungs. There was no enlargement of the liver or of the spleen. The temperature was 102° F. The pulse was soft and full, numbering 92 per minute. The respirations were easy and numbered 28. In the evening the patient complained of very severe headache confined to the frontal region. The temperature was 103·4° and the pulse was 112, while the respirations had increased in rapidity to 30 per minute.

*On August 26th* there was practically no change in the patient's condition. The morning and evening temperatures were respectively 102° and 101·8°, and the corresponding pulse-rates were 72 and 80.

*On August 27th* the morning and evening temperatures were 102° and 100·4°, and the pulse-rates were 76 and 80. Though the respiration-rates corresponding to these were respectively 30 and 23 there was no evidence of any pulmonary lesion.

*August 28th* was the day of the crisis, the temperature falling during the day from 101·4° to 98·6°, the pulse showing a corresponding drop from 78 to 64. At the same time the headache, which had been a clamant symptom up till that date, disappeared, and although no obvious change had occurred in the bubo in the right groin the tenderness was distinctly less. The patient also expressed herself as feeling much better. Since the occurrence of the crisis there has been up to this date continuous improvement in the patient's general condition, while at the same time most of the redness and œdema have disappeared from the right groin, though a small hard swelling still remains.

*Bacteriological examination.*—Four hours after admission a puncture was made into the glandular mass in the right groin and some blood was withdrawn. From this cover-glass films were made and glycerine agar tubes were inoculated. Immediate examination of the films after staining with gentian violet showed the presence of considerable numbers of short bacilli morphologically identical with the bacillus pestis. The inoculated tubes were incubated at 37° C., and 24 hours later a faint white surface-growth had appeared composed of small translucent colonies. Microscopical examination of cover-glass preparations made from these colonies stained with gentian violet showed, as in the previous case, that they were composed of short, thick bacilli with rounded ends, showing for the most part well-marked bipolar staining and occurring frequently as diplobacilli. When treated by Gram's method the bacillus was decolourised. The appearance of the cultures and stained films placed the diagnosis of the organism as bacillus pestis practically beyond a doubt.

In the hospital the plague patients are isolated in a separate pavilion which is surrounded with a high wall preventing the access of all but those whose business it is to attend the sick. All the discharges, fæces, urine, sputa, &c., are placed in vessels containing a suitable amount of 5 per cent. solution of phenol while kept in the ward. They are removed twice a day and boiled in the cholera autoclave before being passed into the drains. All the soiled linen and bedding are boiled for two hours in a steam boiler before being removed from the plague enclosure. The bulk of the patients' clothes is burned on admission, only the more valuable articles of apparel being retained for disinfection by superheated steam. The nurses have all special overalls for use in the ward.

All the nurses and persons who are in immediate attention on the sick, as well as the resident medical staff, have received an inoculation of Yersin's antiplague serum. This has been used in place of Haffkine's as the epidemic broke upon the hospital with a suddenness which necessitated the employment of the whole staff at present required, and it is considered unsafe to inoculate persons who have been exposed to the plague with Haffkine's serum.

It may be stated to the credit of the nursing staff that we have had no lack of volunteers to attend on the infected persons.

---

## A PRELIMINARY NOTE ON THE OUTBREAK OF BUBONIC PLAGUE IN GLASGOW.

To Dr. Thomas Colvin, late physician to the Glasgow Central Dispensary and extraordinary physician to the Glasgow Victoria Infirmary Dispensary, we owe the following account of the beginning of the outbreak of plague in Glasgow.

At five o'clock in the afternoon of Friday, August 24th, I was called in to see a patient at 57, Thistle-street, which is on the south side of the river Clyde and fully half a mile from Kingston, which is the nearest dock to it. The street is one of the most densely populated in the city, and No. 57 has the reputation of being insanitary. It consists of a tenement of three flats with two entrances to them. The tenement is bounded on the right by another tenement of two flats and on the left by a low-roofed carpenter's shop. In going from the street to the tenement a rectangular passage has to be traversed. This rectangular space is about 25 by 15 yards. In the right hand corner of the space and about four yards from the side of the tenement in which is situated the infected house is an open dustbin. But the important point from a sanitary standpoint is that this space is usually the resting place of hand-barrows which are used by some of the dwellers in the tenement for hawking in the streets herrings or cheap fruit, and it (the space) is not uncommonly the receptacle on Saturday night of putrid herrings and putrid fruit which would be unsaleable on the Monday. Whether the herrings and fruit are in the first instance emptied into the dustbin and then scattered about by the children I cannot say, but the fact remains that I have myself on a Sunday morning seen the place strewn with putrid herrings and fruit and other refuse and even fæces.

The entrance to the part of the tenement in which is situated the infected house is about eight feet long by four feet broad. Up three steps is the first flat with two houses, up 12 steps is the second flat with four houses, and up another 12 steps is the third flat with four houses. In all there are 10 separate houses in one half only of the tenement, having one entrance to them from the space described. Each house has affixed to the outside of the door a little oval ticket on which is stated its dimensions and the number of inmates it is supposed to shelter. These tickets, if I mistake not, were first instituted by my old teacher and ever kind friend, Sir W. T. Gairdner, K.C.B., when medical health officer of the city; and by limiting the number of inmates in each house have proved an effectual means of stamping out typhus fever, which was at one time the scourge of the congested parts of the city such as Thistle-street. The ticket on the affected house stated that the dimensions of the house were 1612 cubic feet, and that it was to shelter four adults. The house itself, which was situated on the right-hand side of the second flat, consisted of two apartments, or what is commonly termed here "a room and kitchen." The part of the house called the kitchen was about five yards by four and the room was about six yards by four. In these two rooms ate and slept and washed and dressed and had their being Mrs. Malloy, aged 40 years (mother), Charles, aged 24 years, spirit salesman (son), Patrick, aged 20 years, slipper-maker (son and now deceased), Agnes, aged 18 years (daughter), Christina,

aged 10 years (daughter and now deceased), and William John, aged three years (son). It is important to note that the two sons did not follow the sea and were not in any way connected with the docks. The spirit shop in which Charles served is in Thistle-street, and the factory in which Patrick worked is in the east-end and away from the shipping.

On entering the house on the afternoon named I was conducted through the kitchen to the bedroom in which lay Patrick Malloy. I was told that he vomited on the previous Tuesday and had been ill ever since. He had "raved" all the previous night and had been so delirious that they could not keep him in bed. I found him to be an ill-developed muscular lad of the working-class. He was evidently in a semi-comatose condition. He was dull, stupid, and very prostrate. I could elicit no answer to any question I put to him regarding his illness; nor did he make any response to a repeated request to put out his tongue. His temperature was 103° F. His pulse was 130, small, and feeble, and the first sound of the heart was indistinct. As my first impression was that I had to deal with a case of acute lobar pneumonia in perhaps a drunkard—for at this stage of my examination I was told nothing about the other patients—I made a careful examination of the chest, but it revealed nothing definite beyond congestive catarrh of both bases. I then thought of enteric fever and made inquiries about the stools. My informant, a neighbour woman, said that he had diarrhœa, and without any suggestion of mine volunteered the information that the stools were like "pea-brae" (the word "brae" is the Scotch equivalent for soup) and had an "awful smell." I asked if he had been having any opening medicine and she said that the medical man had ordered him castor-oil and that it was after this he had had diarrhœa. This was my first information that another medical man had been there before me. I was also told that there was another patient in the kitchen bed, and that a little girl, the sister of the patient I was examining, had died on Monday, August 20th, within 24 hours of being taken ill. The medical man who saw her only 10 minutes before her death had certified the cause of death as being pneumonia. On continuing my examination I tried to find rose-spots on the abdomen, but there were none, and indeed no rash of any kind except a good crop of flea-bites. No enlargement of the spleen could be made out on percussion. The tongue was tremulous and of a typhoid character. There was no vomiting after the first day. The bowels were loose after the castor-oil. He had passed little urine during his illness.

I left him and went into the kitchen to examine his mother. Her illness had begun with vomiting on Wednesday, August 22nd, which had since been very persistent in spite of severe poulticing over the abdomen. She was a well-developed woman of the working class with perhaps excess of adipose tissue. She was quite conscious and her one complaint to me was the vomiting. Her temperature was 102°. Her pulse was 100 and of good strength. The heart sounds were normal. The chest was normal save for a little bronchial catarrh. There were no rose-spots or rash of any kind, except a big erythematous patch on the upper two-thirds of the abdomen, the result of poulticing. Still having enteric fever in my mind, I palpated her right iliac region and she said it was painful. It is very important for the sequel to note that the pain might have extended along the groin, but I had no reason to examine the groin and did not do so. It is still more important to note that she had a distinct painful swelling on the upper third of the anterior surface of the right thigh. I was only informed afterwards of its existence by the medical man who first saw her, and on whose attention being drawn to it by the patient had ordered it to be poulticed. The poultice had either soothed it or she was so anxious about the vomiting that she forgot all about it, for she did not complain of it to me. Her whole appeal was for something to relieve her vomiting. Her tongue was flabby and furred. There was persistent vomiting. There was no diarrhœa and her bowels had been well cleared out with castor-oil. She passed urine freely.

I then noticed a little boy lying beside her in bed and I asked what was the matter with him. I was told that he was now all right, but that he also had vomited on Wednesday and up to that day (Friday) his skin had been "roasting." I made his elder brother lift him out of bed and I examined him. His temperature and all his organs were normal. I could make out nothing the matter with him, but as his elder brother and sister were positive that his skin had been "roasting" for three days I concluded that he had the same disease as the other two patients.

To sum up, what, then, was my diagnosis on the spot on my first and only visit to the house? I excluded at once ptomaine poisoning due to eating diseased meat or fish or putrid fruit, for there was a distinct absence of a sudden and common onset and an abrupt termination. The onset of the disease was gradual and so far as I made out in the following order. Christina vomited and died within 24 hours on Monday, Patrick vomited and was ill on Tuesday, while William John and his mother vomited and were ill on Wednesday. When we find four apparently healthy individuals of the same household struck down within a day of each other with a disease characterised by a temperature of 102° F. I think that it is an easy deduction that the disease must be an acute infectious disease. Hence I had no hesitation in the first part of my diagnosis that the disease was an infectious disease. As to the particular infectious disease I was in doubt.

I did not think of typhus fever, which is said closely to resemble bubonic plague, for I had been fortunate three years ago in seeing a case of that disease in Crown-street, which is the next street parallel with Thistle-street, and in this case there was a well-marked dusky measly rash all over the body. In the Malloy cases there was no rash and the only symptom that might have suggested typhus fever apart from enteric fever was the delirious, semi-comatose prostrate condition of Patrick. I did not think of small-pox although we have it in the city and two months ago I detected a case in Adelphi-street which runs along the foot of Thistle-street. Here again I had a well-marked papular rash to guide my diagnosis.

I did think of enteric fever in an early or obscure stage and believed that probably the classical symptoms of that disease would develop later. The arguments which I marshalled in my mind in favour of enteric fever were (1) the temperature, (2) the suggested pea-soup stools with an offensive odour, and (3) the pain in the right iliac region present in the case of the mother. An additional and strong argument was that in August of last year on exactly the opposite side of the same street I had seen three cases of enteric fever and in the same month within a radius of 500 yards of the same street seven or eight cases of enteric fever. Indeed, the locality in autumn is the happy hunting-ground of the typhoid bacillus. Hence my diagnosis on my first and only examination of the Malloy cases was (1) that they were cases of an acute infectious disease and (2) that they were probably early or obscure cases of enteric fever and that some of the classical symptoms of that disease would develop later, but at any rate they were cases requiring close observation for developments.

Before leaving the house I warned the people that the disease was a dangerous and highly infectious one. I forbade the entrance of all friends and neighbours. I gave them instructions about the utensils the patients were using, and isolated the latter as best I could under the circumstances. I said that I would have them removed to the hospital as soon as possible. My first duty on leaving the house was to seek the medical man who had also seen the patients. I may here say that my reason for not sending for him when I learned in the middle of my examination that he had seen them was that the Malloy type of patient belongs to no man, for he changes his medical attendant with the weather and, as a rule, goes to the cheapest man. Two hours later I found the medical man who had seen the patients before me, and on talking over the matter we both agreed to notify the cases at once as doubtful cases of enteric fever. Half an hour later, or two and a half hours after I had seen them, I notified Dr. A. K. Chalmers that there were three doubtful cases of enteric fever in 57, Thistle-street. While I acted promptly I now regret that I posted the notification in the usual course and did not send a special messenger in the endeavour to have the patients removed to the hospital that same night. I am convinced, however, that little or no mischief was done between my visit and the removal to the hospital, for I had warned the people and partially isolated the sick. The mischief was done during the whole week that they were ill and were being visited by friends and sympathisers from all parts of the city. Dr. Chalmers probably got my notification by the first post the next morning, and Charles Malloy afterwards informed me that his mother and two brothers were removed that day (Saturday) at one o'clock

to the Belvidere Hospital for infectious diseases. On the morning of Sunday, the day following their removal to the hospital, Dr. Knight of the Sanitary Chambers called and informed me that in the hospital a bubo had been discovered in the right groin of Mrs. Malloy and another in the axilla of Patrick. He said that the physicianswere inclined to think that the disease was bubonic plague and he asked my coöperation in detecting similar cases.

I now wish it to be clearly and distinctly noted that during the past three years I have seen typhus fever and small-pox and now bubonic plague within a stone's throw of each other. As for enteric fever, erysipelas, puerperal diphtheria, and especially scarlet fever, measles, and whooping-cough, the district is never free from one or other of these diseases. I speak of five years' experience from morn till night, and sometimes from night till morn, in and out narrow and often filthy entrances, up and down dimly-lit stairs, and through dark and tortuous lobbies into low-roofed, odoriferous, and often pestiferous, single apartments, where you may find six, or even eight, individuals of both sexes eating and sleeping and washing and dressing within the four walls of one room. Why send missionaries and money out of the country when there is such need of it at home as is thus indicated? I have only to add that I found no buboes in these cases, qualifying that statement by saying that I did not specially search for them, nor was my attention directed to them by the patients. It never occurred to my mind—as I am certain it would occur to the mind of no man under the circumstances described and on his first examination—that I had to deal with three cases of bubonic plague.

# THE TENTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

(FROM OUR SPECIAL CORRESPONDENT.)

## THE WORK OF THE SECTIONS.

### *The Dustbin Problem.*

ON Monday, August 13th, the Third Section took into consideration M. Hudelo's report on the removal and treatment of household refuse. In Paris this matter is treated in a more radical and prompt manner than in London. Large dustbins are not allowed. A small portable galvanised metallic box is placed in the yard of each house. The inhabitants bring their refuse, put it into this receptacle, and at night it is placed in the street in front of the house. In the early morning the scavengers come round and empty the contents of these boxes into their carts, but there is an interval during which the *chiffonniers* or rag-pickers may come and take out of these portable dustbins anything which they are capable of utilising. As the street sweepings may also be injurious to health these are likewise removed in the early morning and the streets are washed and swept. The washing is necessary so as to collect and convey to the sewers the small particles of dust which would otherwise remain in the atmosphere. Numerous analyses of the refuse thus collected prove that it contains enough potash, phosphates, and nitrogenous substances to be of value for agriculture, but if so utilised it must be very rapidly removed. It has, therefore, been suggested that the tramway lines extending to distant suburbs might be available for this purpose at night when the ordinary traffic has ceased. Whether tramways or railways are employed the cost of such transit may be greater than the value of the manure. The amount of refuse produced by a large town is much greater than can be utilised in the fields that are not too far off. At present for Paris the three railway companies—the Ouest, the Nord, and the Est—transport refuse to a distance of 100 kilometres at rates which are not prohibitive, but this is not the case with the Paris, Lyon, et Méditerranée Company and the Orléans Company. If the refuse could be sorted and packed in compressed bales then what is useful for agriculture might be sent for the same cost double the distance. It is the space taken, rather than the weight of such refuse, that causes the expense of transit. This raises the question as to whether it is possible to sort and pack such refuse near large towns without creating a nuisance. There is such an establishment at Saint-Ouen-les-Docks which treats some 300 tons of Paris refuse per day. Here the refuse is sorted in a trench which has a double metallic lining (where is the dustyard in or about London which thus protects the subsoil from contamination?) and all corruptible materials are removed by railway-trucks within 24 hours of their arrival. Is this done with equal promptitude in the London dustyards? The rags and paper which the rag-pickers have not carried away are burnt and the "hard core"—galley-pots, tins, &c.—is broken up by a crushing-machine. The weight of the matter which is conveyed by train and used for agriculture is thus reduced 20 per cent. in proportion to its bulk. No nuisance has been created and the health of the workpeople engaged in this industry is satisfactory. The town pays 3½*d.* per ton for the matter removed and this is cheaper than when it does the work itself.

### *Destructors.*

With regard to the use of destructors the results are not always satisfactory. At Copenhagen, at Berlin, and elsewhere it has been necessary to add fuel as otherwise the refuse would not burn. In England the destructors work better because the dustbins contain a large proportion of cinders. In Paris it is estimated that the household refuse amounts to a quarter of a ton per inhabitant per annum and if this could be properly burnt and the heat utilised it would give 2017 horse-power per hour. A lengthy account was given of the various methods of destruction by fire employed in different countries and of the drying process adopted by some towns in America by which the grease is extracted and used for making soap and for other industries. At St. Louis 100 tons of refuse yield £32 worth of manure and £6 8*s.* worth of grease, but this does not cover the working expenses. Altogether the report concluded by recommending the utilisation of refuse for agriculture, where it is possible to convey it immediately to the fields. Otherwise some process of destruction by fire should be employed.

In the discussion which followed it was pointed out that what was thrown away as ashes in England would be looked upon as coal in Holland and that what the Dutch threw away the Germans would still find means of utilising. A destructor that would be workable at Amsterdam would be quite useless at Berlin, for not only were the ashes in the latter town absolutely devoid of any cinders, but there was a great deal of fluff from the cloth industries which would not burn. In the same manner the value of refuse as manure differed greatly according to the occupations and customs of the people from whom it was collected. It was, therefore, impossible to lay down any hard-and-fast principle. Finally, the section resolved to adjourn the whole question to a future Congress.

### *The Protection of Water Within the Dwelling.*

The next report was by M. Lacan, Vice-President of the French Society of Sanitary Architects and Engineers, and by M. Louis Masson, engineer and inspector of the Paris sewers and dwellings. It dealt with domestic sanitation and the connexion of houses with the sewers. Plenty of pure air and pure water were agreed to be the first of necessities. But though at first the water might be pure if the pipes were occasionally empty the air might oxidise the lead and thus poison the water. In the country districts it was well known how easily wells were contaminated. Nevertheless it was easier to protect the water than the atmosphere. The water must not be allowed to come into contact with the air. Even if perfectly pure in the main the connexions with the house were often dangerously defective. The pipe might be either too small or too large for the amount of water it had to deliver, there might be too many bends or angles, or the plumbing of the joints might be carelessly done. All this required careful calculation so that the pipes within the dwelling might deliver the amount of water required without causing a vacuum in the delivery pipe. The size of the taps must be in proportion with their number and the size of the principal pipe within the house, so that the opening of two taps at the same time should not empty the main house pipe and cause air to enter. Of course the water for flushing the closets should not be taken direct from the main but from a disconnecting flushing tank, or "waste preventer," as it is called in England. Naturally the employment of cisterns to store the supply of drinking-water, which are so largely used in London, was absolutely and emphatically condemned. It was impossible to prevent dust and emanations in gaseous form reaching and contaminating such cisterns. As for the use of domestic filters these required so much care and were at best of such doubtful utility that a warning against the dangers they occasion was very necessary.

*The Ventilation of Private Dwellings.*

In respect to the unsolved problem of the ventilation of private dwellings, the report treated of a phase of the subject which in England is singularly neglected, namely, the porosity of the walls. A house covered with impermeable paint or other similar substance required far more ventilation than was the case where the natural porosity of the walls was preserved. As in winter it was difficult to keep windows open, ventilating shafts should be brought behind the fireplaces so that the outside air might be partially warmed before it was discharged into the room. The only absolutely certain method of ventilation was when mechanical power was employed, and the reporters seemed to think that this could only be applied to large buildings or assembly rooms. But with a little jet of water or a weak electric current the very slight amount of power necessary to move a small fan could be secured and for no very large cost; and such methods could be and are utilised in private dwellings.

*Public Sewers.*

With regard to house refuse the ideal would be its destruction by fire as rapidly as it is produced. But it was not every house that possessed a sufficiently good oven and fire to burn up at once the dust collected in sweeping and the vegetable and animal refuse from the kitchen. In regard to drainage the report first stated that where cesspools had been abolished and houses placed in connexion with sewers there the death-rate had been greatly reduced. This was quite true, but the reporters were too sweeping in their condemnation of the separate system, of mechanical and pneumatic apparatus, &c. They forgot that where there was no fall some sort of mechanical apparatus must be and was employed to raise the sewage or propel it forward and that where the separate system had been applied there had likewise been a great decrease in the death-rate. In Paris itself immense engines are employed to raise the sewage so that it may flow on to the irrigation plains of Achères, &c. This is machinery, and very costly machinery; and in some towns it has been found more expedient to use a larger number of smaller machines, distributed in different directions. In Berlin there are six such centres; and where pneumatic apparatus is employed, as at Bombay, Rangoon, Southampton, &c., a still greater number are employed and still greater economy is realised. That water carriage, as the reporters argued, is the simplest of methods is undeniable; but where there is no fall the water will not carry, and a fall below a flat surface cannot be artificially created for any considerable distance. Consequently the sewers of Paris, of London, and of many other towns are apt to be clogged with deposits. They are not self-cleansing; scavengers armed with all manner of ingenious apparatus have to be sent down to clear these sewers. It is not drainage by water carriage, but by human labour. If any machinery can effectively replace human labour of such a description it merits careful consideration from all sanitary reformers. As the report deals with domestic drainage and not with public sewers the reporters would have been better advised had they left this latter subject alone instead of going out of their way to condemn systems, theories, and methods which were not under discussion.

*Soil-pipes as Sewer Ventilators.*

Dealing with the internal arrangements of the house, the principles proclaimed will find very general acceptance. Every tenement should have its own water-closet, for those used in common by several families can never be clean. A vigorous, and as far as possible an instantaneous, flush should be provided. A water-sealed syphon should be placed under every closet-pan, sink, bath waste pipe, &c. The seal of these traps should be two inches deep. The rain as well as the slop-water should drain into the main soil-pipe of the house and the diameter of this pipe should be small. In France it is generally much too large. The soil-pipe should continue to the roof of the house and be left open and, of course, should be absolutely watertight. It should be occasionally tested with smoke or water to see that there is no leakage. The water test is the most reliable.

So far everyone was agreed, but as soon as the reporters approached the subject of the public sewers divergences of opinion became manifest. Indeed, the discussion which followed was in the main devoted to the question now raised — namely, should there be a trap at the bottom of the house soil-pipe so as to disconnect it from the public or street sewer? The reporters were opposed to the use of these disconnecting traps, which were first employed when the sewers were badly built and the sewer airs really dangerous; "but now it is recognised that the hypothesis that the diffusion of epidemical diseases such as typhoid fever, cholera, and diphtheria, by sewer-gas is incompatible with our actual knowledge of the principles that govern the propagation of these maladies." Then, again, we were told that the disconnecting trap prevented the utilisation of the soil-pipes for the ventilation of the sewers and the circulation of air in the soil-pipes. This latter assertion shows a confusion in the authors' minds between what in England is meant by a disconnecting trap or chamber and a mere syphon. The disconnecting trap or chamber should be provided with an air inlet for the ventilation of the soil-pipe of the house. It is best that this inlet should be carried to the top of the house, as then it does not matter whether it acts as an inlet or outlet. In any case the soil-pipe must have two apertures, one consisting of the continuation of the pipe itself to the top of the house and the other communicating with the soil-pipe just before it reaches the syphon that separates it from the sewer. Then there can be no pressure on the traps, even if the pipe should be blocked in any part of its course. Of course it is easy to condemn the disconnecting trap when improperly constructed and this is precisely what was done and what should be done; but no account was taken of cases in which the system was properly and satisfactorily applied. In justice, however, it must be said that the term "disconnecting trap" was only occasionally employed and that the section had but vague ideas as to what this sort of trap might be. The terms more generally used were *siphon terminus* or *siphon de pied*. Of course, a simple syphon at the end or foot of the soil-pipe may very justly be condemned unless and apart from the ordinary outlet an air inlet is added to such a syphon. Then it is that it becomes not a simple syphon or trap but a *disconnecting* trap. A syphon which is affixed to an unventilated pipe does not disconnect, because the water-seal is constantly broken by the pressure or suction frequently occurring in the pipe. Had the report made this distinction clear a great deal of unnecessary discussion would have been avoided.

The experiments made by the British Sanitary Institute were quoted to show that with the ordinary two-gallon flush soil remained in the trap which separated the soil-pipe from the sewer. This, then, was against the principle that all such putrescent matter should be immediately carried away. To flush such traps properly it would be necessary greatly to increase the water-supply. The report therefore urges that these traps should be done away with and that every domestic soil-pipe should become a ventilator of the sewer. The plentiful supply of oxygen thus secured would "burn up the injurious microbes as fast as they are produced." This latter sentence is in flat contradiction with the assertion previously made that sewer air did not propagate epidemical diseases.

Mr. ROECHLIN (Leicester) while agreeing in many respects with the opinions expressed in the report submitted to the section, spoke strongly in favour of the disconnecting trap. Where in the experiments of the British Sanitary Institute the flush had not sufficed to clear the trap it came from a closet in the cellar, that is to say, on nearly the same level. In Paris, where the houses were so lofty, the flush would acquire sufficient velocity to clear out everything from the trap. He had examined houses where an obstruction occurred and this happened not necessarily in the disconnecting trap but in various parts of the systems. M. EMILE TRELAT thought that it was a matter of detail of application rather than a question of a general principle. Dr. Vaillant was in favour of suppressing the *siphon de pied*. Pasteur had explained that there were two sorts of fermentation, and that the fermentation which took place in contact with the air was not dangerous. M. DONKOWSKI from Russia argued that if a trap was placed at the bottom of the soil-pipe people would conclude that all that was necessary had been done, and would not take trouble to put traps under the closet-pans and waste-water pipes. If the latter syphons were properly inspected there was no need of a disconnecting trap. Mr. ADOLPHE SMITH protested against the assertion that recent bacteriological discoveries justified the belief that sewer air was not injurious. Even if such emanations from the sewers did not contain pathological bacteria it was quite certain that they predisposed persons to disease. Practically

the result was the same. It had been said, however, that scavengers who worked in the sewers enjoyed good health. Doubtless this was the case, but they were poor men who had for the most part been reared in unhealthy homes, and having survived they might be considered immune. Then they were in the prime of life, they did not work in sewers at a susceptible age, and when in the sewers their bodies were in full activity. The greatest danger was when vitality was at its lowest ebb—namely, during sleep. Now, if the soil-pipes of private houses were to be converted into ventilating shafts for the public sewers, would not sewer air be discharged into bedroom windows? This danger would be especially great where the ground was not absolutely level and houses overlooked each other. The speaker illustrated this by describing how at Maidstone typhoid fever had followed the level of a sewer ventilator. Sewers should be amply ventilated, but in suitable places and not haphazard on the roof of every house, without regard to windows that might be close by and at higher levels. No general rule could be laid down. Here and there a soil-pipe could be utilised as a sewer ventilator, but this could not be applied on all sides whatever the character of the houses and of the ground. Dr. RICHAUD agreed that it was not possible to dogmatise, and Dr. REYNAULD said that if in the small towns of Austria a syphon was placed at the bottom of the soil-pipe there would not be enough air in the sewers and people would neglect to put traps in their houses. The soil-pipe air could be as dangerous as that of the sewer. M. BECHMANN brought the discussion to a conclusion by insisting that the section should strive to indicate what were the results that were to be attained rather than the means to be employed. Thus the use of disconnecting traps might well be left to be decided according to local circumstances. The section might be content with insisting that domestic drains should be so constructed as to be free from odour and to ensure the immediate evacuation of the soil. A resolution to that effect was thereupon carried. It further stipulated that all apertures leading to the soil-pipe should be trapped in such a manner as to prevent the entry of air from the pipe or the sewer into the dwelling. Further, the soil-pipe should be permanently ventilated throughout. Another resolution was carried insisting that special care should be given to improve all plumbing work and that all water-pipes, traps, and soil-pipes should be so placed and built as to be free from the effects of frost. The section then adjourned.

*(To be continued.)*

## ASYLUM REPORTS.

*Royal Lunatic Asylum, Montrose (Annual Report for 1899).*—Overcrowding had been felt for some time at this asylum and it was decided to build a detached block or villa to relieve the congestion. This has been so far carried out that it was expected that the villa would be ready for occupation by September. The cost of erection was estimated at £7000. As, however, this would provide only for one-half, or the male portion, of the overcrowding at the asylum, the committee are now considering plans for the erection of another house to accommodate the female surplus. The average number of patients resident during the year at the asylum was 659. 75 males and 89 females were admitted during the year, making a total of 164 patients admitted. Of these 138 were new cases and 26 were re-admissions. 126 of the admissions were rate-supported, while 38 were private patients. Dr. John G. Havelock, the medical superintendent, states in his report that intemperance in drink was the cause of insanity in 13 per cent. of the admissions. Hereditary predisposition was the cause in 11 per cent., old age in 10 per cent., and moral causes accounted for another 10 per cent. In 25 per cent. of the admissions no cause could be ascertained. There was a history of previous attacks in 27 per cent. of the cases admitted. In nine cases influenza was the exciting cause of the attack. The number of patients discharged as recovered was 68—i.e., 30 males and 38 females, or 10·3 per cent. of the average number resident. The deaths during the year amounted to 59, or 30 males and 29 females—i.e., 8·9 per cent. of the average number resident. The causes of death were as follows: three deaths were due to epilepsy, three to cerebral hæmorrhage, two to renal disease, five to malignant neoplasms, five to pneumonia, six to senile decay, six to general paralysis of the insane, seven to phthisis and other forms of tuberculosis, and 14 to cardiac disease. Post-mortem examinations were made in only 35 out of the 59 deaths. Several cases of influenza occurred in the institution during the winter months, but the epidemic was less virulent than in previous years. The Commissioners in Lunacy in their reports state that the institution is well managed and that the books and registers are correctly and regularly kept. The farm and garden account showed a surplus during the year of over £275. As authorised by the managers the committee have negotiated a loan of £15,000 in order to meet the balance of expenditure for Carnegie House and Lodge (the parts of the institution for the admission and accommodation of private patients) and for the new villas now in course of erection. Owing to increased annual outlay in recent years the committee propose to raise the rate of board for all pauper patients to £32 per annum in future, which is the minimum rate of board charged by any of the other chartered asylums in Scotland.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6832 births and 4404 deaths were registered during the week ending August 25th. The annual rate of mortality in these towns, which had declined from 20·5 to 19·5 per 1000 in the three preceding weeks, rose again to 19·8 in the week under notice. In London the rate was 19·2 per 1000, while it averaged 20·1 in the 32 provincial towns. The lowest death-rates in these towns were 11·3 in Cardiff, 11·4 in Swansea, 13·2 in Bradford, and 13·5 in Halifax and in Croydon; the highest rates were 25·5 in Salford, 25·9 in Sheffield, 28·6 in Plymouth, 28·5 in Wolverhampton, and 30·7 in Preston. The 4404 deaths in these towns included 1180 which were referred to the principal zymotic diseases, against 1263 and 1061 in the two preceding weeks; of these 883 resulted from diarrhœa, 117 from whooping-cough, 62 from measles, 50 from diphtheria, 44 from "fever" (principally enteric), and 24 from scarlet fever. The lowest death-rates from these diseases were recorded in Bradford, Swansea, Cardiff, and Halifax; and the highest rates in Preston, Wolverhampton, Plymouth, and Hull. The greatest mortality from measles occurred in Gateshead, Leeds, Brighton, and Oldham; from whooping-cough in Gateshead, Nottingham, and Derby; from "fever" in Portsmouth; and from diarrhœa in Leicester, Sheffield, Preston, Wolverhampton, Plymouth, and Hull. The mortality from scarlet fever showed no marked excess in any of the towns. The 50 deaths from diphtheria included 14 in London, seven in Leicester and in Leeds, and three in Sheffield and in Salford. No fatal case of small-pox was registered in the week in any of the 33 large towns and only one case was under treatment in the Metropolitan Asylums Hospitals at the end of the week. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday, August 25th, was 1726, against 1827, 1838, and 1793 the three preceding weeks; 140 new cases were admitted during the week, against 156, 155, and 177 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 128 to 132 in the two preceding weeks, further rose in the week under notice to 149, but were 12 below the corrected average. The causes of 47, or 1·1 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Nottingham, Salford, Bradford, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in Portsmouth, Leicester, and Liverpool.

### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined from 19·0 to 16·9 in the five preceding weeks, rose again to 17·9 per 1000 during the week ending August 25th, and was 1·9 per 1000 less than the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 11·8 in Perth and 16·6 in Leith to 23·3 in Paisley and 24·9 in Greenock. The 554 deaths in these towns included 52 which were referred to diarrhœa, 23 to whooping-cough, nine to measles,

eight to "fever," six to diphtheria, and five to scarlet fever. In all 103 deaths resulted from these principal zymotic diseases, against 107 and 108 in the two preceding weeks. These 103 deaths were equal to an annual rate of 3·3 per 1000, which was 2·0 below the mean rate in the week from the same diseases in the 33 large English towns. The fatal cases of diarrhœa, which had been 60 and 56 in the two preceding weeks, further declined to 52, of which 17 occurred in Glasgow, seven in Paisley, and seven in Greenock. The deaths from whooping-cough, which had been 27 and 18 in the two preceding weeks, rose again to 23, and included 15 in Glasgow, four in Greenock, and three in Dundee. The fatal cases of measles, which had been 11 and 16 in the two preceding weeks, declined in the week under notice to nine, of which four were registered in Glasgow and four in Edinburgh. The deaths from diphtheria numbered six, against none and seven in the two preceding weeks, and included three in Glasgow and two in Greenock. The five cases of scarlet fever, three of which occurred in Glasgow, showed a decrease of one over the number in the preceding week. The deaths from "fever," which had been five in each of the two preceding weeks, rose again to eight, four of which were recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 67, 52, and 59 in the three preceding weeks, rose again to 82, and were greatly in excess of the number in the corresponding period of last year. The causes of 17, or 3 per cent., of the deaths in these eight towns last week were not certified.

### HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined from 24·0 to 21·2 per 1000 during the three preceding weeks, rose again to 27·0 during the week ending August 25th. During the four weeks ending August 25th the death-rate in the city averaged 23·8 per 1000, the rate during the same period being 19·8 in London and 15·8 in Edinburgh. The 181 deaths belonging to Dublin registered during the week under notice showed an increase of 39 on the number in the preceding week, and included 33 which were referred to the principal zymotic diseases, against 14, 23, and 28 in the three preceding weeks; of these 25 resulted from diarrhœa, five from whooping-cough, three from "fever," and not one from small-pox, measles, scarlet fever, or diphtherla. These 33 deaths were equal to an annual rate of 4·9 per 1000, the zymotic death-rate during the same period being 4·7 in London and 1·7 in Edinburgh. The fatal cases of diarrhœa, which had been 19 and 24 in the two preceding weeks, rose to 25. The five deaths from whooping-cough showed a marked increase, having been one in each of the two preceding weeks. Three cases of "fever," were equal to the number recorded in the preceding week. The 181 deaths in Dublin included 62 of infants under one year of age and 20 of persons aged upwards of 60 years; the deaths of elderly persons showed a decline, while those of infants greatly exceeded the number recorded in the preceding week. Six inquest cases and nine deaths from violence were registered, and 65, or slightly more than one-third, of the deaths occurred in public institutions. The causes of 5, or nearly 3 per cent., of the deaths in the city during the week were not certified.

## THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: F. J. Burns to the *Tauranga;* C. M. Beadnell and J. E. Coad to the *Scylla.* Surgeons: C. Shepherd to the *Royal Arthur*; C. R. Nicholson to the *Nile;* and R. Waterfield to the *Nymphe.*

### ROYAL ARMY MEDICAL CORPS.

Captain D. J. Collins has been appointed for the performance of "specially arduous plague duty" in Poona Cantonment and Suburban Municipality, in addition to his military duties, vice Lieutenant E. F. Gordon Tucker, I.M.S., who has proceeded on service to China. Major W. Turner has embarked for South Africa. Captain H. W. Vaughan-Williams has been placed on half-pay in consequence of ill-health. Lieutenant-Colonel G. F. Poynder has retired on half-pay.

The following is the list of successful candidates for commissions in the Royal Army Medical Corps at the recent examination in London:—

| Names in order of merit. | Marks. | Names in order of merit. | Marks. |
|---|---|---|---|
| 1. H. J. McGrigor ... ... | 2779 | 6. C. D. Myles... ... ... | 2040 |
| 2. W. R. P. Goodwin ... | 2612 | 7. R. N. Hunt ... ... ... | 1986 |
| 3. J. H. Brunskill ... ... | 2303 | 8. H. E. Howley ... ... | 1916 |
| 4. A. C. Duffey ... ... | 2251 | 9. R. F. M. Fawcett ... | 1855 |
| 5. A. W. Gibson ... ... | 2205 | | |

### ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant Arthur Young Pringle, 1st Suffolk and Harwich Volunteer Artillery, has been appointed Surgeon-Lieutenant.

### INDIA AND THE INDIAN MEDICAL SERVICES.

The services of Captain H. Ainsworth, on plague duty in the Jullunder District, have been placed at the disposal of the Government of India in the Home Department. Lieutenant J. C. H. Leicester has been appointed to the officiating medical charge of the 1st Central India Horse. Lieutenant-Colonel D. P. Warliker has been permitted to return to duty. Captain E. V. Hugo has been appointed to officiate as civil surgeon of Kangra. The following officers have retired from the service: Lieutenant-Colonel C. J. McCartie, Lieutenant-Colonel D. W. D. Comins, and Lieutenant-Colonel J. F. Tuohy. Lieutenant-Colonel J. T. B. Bookey to be Colonel. Captain H. Smith has resumed civil medical charge of the Jullunder district. Lieutenant H. Boulton has assumed charge of the civil medical duties of Bannu. Major J. K. Close, civil surgeon, Moradabad, will hold visiting medical charge of the Budaun district in addition to his own duties during the absence on leave of Major A. R. W. Sedgefield. Captain C. Milne, officiating civil surgeon, is transferred from Jaunpur to Benares as a temporary measure. The services of Major R. J. Marks, officiating civil surgeon, Etawah, are replaced at the disposal of the Government of India, Home Department. The following officers of the Indian Medical Service proceeding to China have arrived in Calcutta: Lieutenant G. McPherson, Lieutenant J. W. Rait, and Lieutenant D. N. Anderson. Major Sykes, Captain Evans, Captain Moncrieff, and Captain Tucker have left Bombay in the hospital ship *Carthage.* The services of Major J. W. Rodgers and Captain E. S. Peck, civil surgeons in the Punjab, have been placed at the disposal of the Government of India for service with the China expedition. Furlough to Europe for one year has been granted to Captain S. A. C. Dallas, civil surgeon, Chanda.

The following candidates for the Indian Medical Service were successful at the competitive examination held in London on August 17th, and following days:—

| Place. | Marks. | Place. | Marks. |
|---|---|---|---|
| 1. C. W. Melville ... ... | 3476 | 8. W. H. Leonard ... ... | 2786 |
| 2. N. S. Wells ... ... ... | 3033 | 9. J. E. G. Swan ... ... | 2737 |
| 3. R. McCarrison ... ... | 3005 | 10. R. McL. Dalziel... ... | 2548 |
| 4. J. Masson ... ... ... | 3000 | 11. A. W. C. Young... ... | 2500 |
| 5. W. M. Anderson ... | 2991 | 12. J. J. Robb ... ... ... | 2430 |
| 6. W. D. Pringle ... ... | 2985 | 13. S. A. Ruzzak ... ... | 2425 |
| 7. E. H. B. Stanley ... | 2870 | 14. R. B. B. Foster ... ... | 2385 |

### MILITIA.

4th Battalion Suffolk Regiment: Surgeon-Lieutenant-Colonel F. Fawssett, jun., Militia Medical Staff, retires with permission to retain his rank and to wear the prescribed uniform on retirement.

### MILITIA MEDICAL STAFF CORPS.

Mr. George James Devonsher Davies to be Surgeon-Lieutenant. Surgeon-Major W. Waring to be Surgeon-Lieutenant-Colonel. Surgeon-Captain W. M. O'Connor, M.B., to be Surgeon-Major.

### YEOMANRY CAVALRY.

Royal Wiltshire: Surgeon-Lieutenant O. C. Maurice to be Surgeon-Captain.

### VOLUNTEER CORPS.

*Artillery:* Surgeon-Lieutenant George Higginson resigns his commission and is appointed Second Lieutenant. *Rifle:* Queen's Rifle Volunteer Brigade (Highland Battalion) Lothian Regiment (Royal Scots): Kenneth MacKinnon Douglas, to be Surgeon-Lieutenant. 2nd Volunteer Battalion Northumberland Fusiliers: Surgeon-Lieutenant A. W. Messer resigns his commission. 2nd Volunteer Battalion Lincolnshire Regiment: Surgeon-Major G. F. England to be Surgeon-Lieutenant-Colonel. 5th Volunteer Battalion South Wales Borderers: Surgeon-Lieutenant C. E. Humphreys to be Surgeon-Captain.

### TRANSVAAL WAR NOTES.

The following officers have been discharged from hospital to duty:—Major G. Brazier-Creagh, R.A.M.C., Major D. Bruce, R.A M.C., Lieutenant M. H. Babington, R.A.M.C., and Lieutenant W. J. P. Adye-Curran, R.A.M.C.

The transport *Templemore* has arrived at Southampton with 10 officers and 390 men sick and wounded from South Africa.

The transport *Orotava*, with sick and wounded from South Africa, has disembarked at Southampton 35 officers and 590 men convalescent for Brockhurst and for Netley Hospital.

Lieutenant-Colonel R. D. Hodson, R.A.M.C., invalided, has left Cape Town for England.

Lieutenant W. H. S. Nickerson, R.A M.C., was one of those taken prisoner at Klipfontein.

Colonel W. F. Stevenson, R.A.M.C., has been granted the temporary rank of surgeon-general whilst principal medical officer at army head-quarters, South Africa.

The Secretary of State for War has approved of officers on sick leave from South Africa who reside within a mile of any military hospital being allowed free medical attendance from an army medical officer or civil surgeon engaged for duty with the troops.

### THE WAR IN CHINA.

We do not think that the gallant attempt which Admiral Seymour made to relieve the legations in Peking has aroused the attention or obtained the credit in this country which it merited. It was full of incidents illustrating the pluck and devotion of the men of the various nationalities taking part in it. The conduct of Admiral Seymour and of his contingent was worthy of the best days of our navy and was highly, as well as generously, appreciated on the part of the officers of the United States' navy, with whom Admiral Seymour's character and ability rank very high. We are glad to notice that the services rendered by the French officers and sailors under singularly critical circumstances, and especially the conduct of the Flag-Captain, de Marolles, were most handsomely recognised, as they well deserved to be, by Admiral Seymour in his letter to Admiral Courrejolles. There is no need to dwell upon the more recent operations in the notable achievement of the relief of Peking by the allied forces; the marches over a single difficult road in sickening hot weather; the stubborn courage and discipline of the troops—especially the Japanese, who fight like Gorkhas—and of the dysentery and disease attributable to bad water, bad food, and fatigue; these things have been fully set forth in the daily press. Peking was captured and the legations were saved in the very nick of time and so far all is even more satisfactory than could have been anticipated a few weeks ago, though the political difficulties have not by any means been cleared away.

As regards the military force from India now operating in China under the command of General Gaselee it will probably have to be augmented, and must in any case be supplied with reinforcements to make up for losses by wastage. The Indian Government have for the present equipped the force with medical officers and hospitals, but the question will shortly arise as to where the requisite number of medical officers can be obtained. The Indian medical establishment is a limited one and the calls on it in India have been very great, and, as everyone knows, show no sign of diminishing.

### THE SOUTH AFRICAN HOSPITALS INQUIRY.

Amidst all the *ex-parte* statements that have appeared on one side and the other it is gratifying to notice that there is a decided preponderance of testimony in favour of the good work done by the Army Medical Corps in South Africa. Several of the colonial soldiers on the occasion of their late visit to Windsor Castle spoke very emphatically of their personal experience in this respect and as their testimony was perfectly spontaneous and they knew of what they were talking about it was reliable and valuable. They freely acknowledged that whatever shortcomings there might have been were of a temporary nature and simply unavoidable and attributable to the strain and stress of war. The testimony of soldiers who have passed through the hospitals in South Africa is, after all, the best test that can be applied and it is almost uniformly favourable; and where it is not their criticism is nevertheless usually perfectly fair, temperate, and just. With regard to the overcrowding of army hospitals people seem to forget that this is occasionally unavoidable. A military hospital, unlike a civil one, is bound to take in and provide for sick and wounded soldiers after an action or outbreak of epidemic disease. The *Spectator* of last week contains a very pertinent and well-written remonstrance from Lieutenant-Colonel N. Alcock, a retired officer of the Army Medical Staff, against attacks (with one of which he deals in particular) upon the *personnel* of the Royal Army Medical Corps, who are silently doing their duty in this war often under most trying circumstances. All interested should read this communication.

### PASTEUR INSTITUTE FOR INDIA.

The Pasteur Institute has been opened at Kasauli for the treatment of persons bitten by rabid animals. The director of the institute at Kasauli is Major D. Semple, R.A.M.C., who was Assistant Professor of Hygiene at Netley for several years, and has been trained in bacteriology and studied the anti-rabic treatment in Paris. The treatment itself at Kasauli will be entirely gratuitous, but as it does not involve detention in hospital patients will have to make their own arrangements for board and lodging. Excellent accommodation for all classes can be found at this station. Soldiers bitten by rabid animals will no longer require to be sent from India to Paris for treatment. Major Semple has already had eight men of the South Staffordshire Regiment sent for treatment from Subathu, and applications for admission have been made in the case of sepoys and other natives from various parts of the Punjab and the North-West Provinces.

### "HEROES ALL."

We have received from the London Stereoscopic Company, 54, Cheapside, London, E.C., a tasteful engraving having the above title and presenting on the central figure a portrait of Field-Marshal Lord Roberts surrounded by ten portraits of generals and colonels serving under him. It has been prepared as a souvenir picture of our generals in South Africa, and the London Stereoscopic Company offers to send, gratis and post free, as many copies of "Heroes All" as may be applied for by the managers of every hospital, sick ward, convalescent home, or other resort where our invalided soldiers and sailors returned from South Africa are being treated, in order that these souvenirs may decorate the walls and interest the invalids. Presentation copies have been graciously accepted by the Queen and several members of the Royal Family.

### THE CASUALTIES IN SOUTH AFRICA.

The total losses (exclusive of sick and wounded men now in British hospitals in South Africa) amount to over 40,000 and of these between 5000 and 8000 have died from disease, which is very considerably in excess of the number of deaths returned as killed and wounded. As the *Army and Navy Gazette* points out, however, we have been engaged for some ten months in this war and the losses in killed and wounded amount in round numbers to 10 per cent. of the mean strength of the forces actually landed in the theatre of war. In ten hours' fighting at Gravelotte, to take one instance, the victors lost almost exactly the same numbers out of about half the strength engaged.

### ROYAL VICTORIA HOSPITAL, NETLEY.

On August 31st Lord Lansdowne, Secretary of State for War, who was on a visit to Her Majesty at Osborne, paid a visit of inspection to the Royal Victoria Hospital, Netley. Crossing from Cowes in the royal yacht he was received by Lieutenant-Colonel W. E. Webb, the officiating principal medical officer. After going round the hospital he visited the huts and inspected the new railway station and line.

### THE MEDICAL OFFICERS ORDERED FOR CHINA.

The medical officers warned by the War Office to prepare for service in China at 48 hours' notice were informed on Saturday last that, for the present at least, their services will not be required.

---

SWANSEA GENERAL HOSPITAL.—The committee of management of this institution have elected Dr. Henry A. Latimer, J.P., as their chairman.

NAVAL INVALIDS.—The steamship *Palawan* arrived at Plymouth on August 27th and landed 22 naval invalids from the Mediterranean Squadron suffering from Mediterranean or malarial fever. They were conveyed to the Royal Naval Barracks at Stoke.

# Correspondence.

"Audi alteram partem."

## "THE MEDICAL STAFF AND THE MANAGEMENT OF THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE."

*To the Editors of* THE LANCET.

SIRS,—The following correspondence throws, I think, a helpful sidelight on the controversy as to the management of the National Hospital for the Paralysed and Epileptic and illustrates the sort of tactics that have been resorted to in the long-sustained campaign against the medical staff.

With reference to the special general meeting on August 11th it is now clear:—

1. That it was summoned, notwithstanding the protest of the medical staff, deliberately—perhaps I should say precipitately—for a date when it was impossible for any considerable proportion of the governors or subscribers to attend it or for the medical staff to be represented at it.

2. That its decision was taken on a statement of facts which Mr. G. W. E. Russell has, in the columns of the *Times*, admitted to be incorrect, but which is still being circulated amongst the governors and subscribers by the authority of the board of management.

3. That it was a packed meeting, made up of friends of the board of management specially invited. True, the packing was on a small scale, as only 16 persons took part in the proceedings, but there was packing nevertheless.

I shall be greatly surprised if a properly convened and informed meeting of the governors held at a convenient time does not emphatically reverse the decision arrived at on August 11th. I am, Sirs, yours faithfully,

London, August 31st, 1900. JAMES CRICHTON-BROWNE.

---

61, Carlisle-place-mansions, Victoria-street, S.W., August 23rd, 1900.

DEAR MR. BURFORD RAWLINGS,—I have received "with the compliments of the board of management" a report of a special meeting of governors and subscribers of the National Hospital held on the 11th of August.

Will you be good enough to inform me why, as a governor, I was not summoned to that meeting and had no notice of it?

I understand that certain governors were invited to attend that meeting and were asked for proxies, and I should be glad to know on what principle a selection of governors to be specially summoned was made.

I shall be obliged if you will send me a copy of the last annual report of the hospital and of the rules and regulations under which it is governed. Believe me, yours faithfully,

R. Burford Rawlings, Esq. JAMES CRICHTON-BROWNE.

National Hospital for the Paralysed and Epileptic, Queen-square, Bloomsbury, August 24th, 1900.

DEAR SIR JAMES CRICHTON-BROWNE,—I beg to acknowledge the receipt of your letter of yesterday.

In reply let me say that no selection of governors to be specially summoned to the general meeting on the 11th inst. was made.

The meeting was summoned in the way provided by the rules - viz., by public advertisement. In addition it was announced in the board's letter to the *Times*, and was mentioned in subsequent communications to that journal.

When the proxies were sent out it was thought to be obviously out of place to solicit the support of the friends of the medical staff. Such an act would have been regarded as an impertinence.

I am sending you a copy of the last report—one was forwarded at the time of issue in May—and I am also sending you, as you wish, a copy of the rules for the constitution of the charity.

Believe me to remain, yours faithfully,

B. BURFORD RAWLINGS.

Sir James Crichton-Browne, F.R.S.

61, Carlisle-place-mansions, Victoria-street, S.W., August 25th, 1900.

DEAR MR. BURFORD RAWLINGS,—I have to thank you for your letter of yesterday's date and for copies of the last annual report and rules of the National Hospital.

I gather from the rules that a single advertisement in any "one public journal" would be an adequate notice of a special general meeting, and I have no doubt, therefore, that the meeting on the 11th inst. was in a technical sense duly summoned, although, as I did not see your advertisement, I had no notice of it. If all the other governors and subscribers are in the same case I have no right to complain, but I have been told that a certain number of governors outside the board of management did receive special notice of the meeting, and your admission that proxies were sent out is tantamount to an acknowledgment that this was so.

Will you explain how you reconcile the issue of proxies with "Rule 6, section, general meetings," which requires that every question shall be decided by a majority of governors present at the meeting? Will you also explain how before issuing your proxies you were able to discriminate in the large body of governors those who were "friends of the medical staff," and to whom it would be "an impertinence to send them," and those who were friends of the board of management and were therefore favoured with them? Most of the governors will, I believe, prefer to be regarded as friends of the National Hospital and will insist on a fair opportunity of giving effect to their views in the controversy which has unhappily arisen.

Believe me, yours faithfully,

R. Burford Rawlings, Esq. JAMES CRICHTON-BROWNE.

National Hospital for the Paralysed and Epileptic, Queen-square, Bloomsbury, August 30th, 1900.

DEAR SIR JAMES CRICHTON-BROWNE,—I am so sorry that my reply to your letter of the 25th has been delayed. Will you accept my apologies for what has been entirely unintentional?

You are correct in your reading of the rules, as to a single advertisement being sufficient for calling a special general meeting. The special meeting to which you refer was, however, the subject of more than one letter in the *Times* newspaper in addition to being called by advertisement in that journal.

In sending out the proxies it was explained that they were for use if a ballot should be demanded. They could not, of course, be used at the meeting when, as you correctly point out, all questions had to be decided by the governors present. Naturally the board did not send proxy papers in support of their policy where it was known they would be unwelcome, and I think you would have had reason to complain if you had been asked to give a proxy in favour of the board and against the staff. It was only in cases like your own when, as I said in my former letter, a request to support the board might have been rightly regarded as an impertinence, that an appeal for such support was not made.

Believe me to remain, yours faithfully,

Sir James Crichton-Browne, F.R.S. B. BURFORD RAWLINGS

---

## "PROFESSIONAL ORGANISATIONS."

*To the Editors of* THE LANCET.

SIRS,—On behalf of the Great Yarmouth District Committee of the Incorporated Medical Practitioners' Association I am directed to reply to the letter from Dr. James Ryley, published in THE LANCET of August 25th (p. 627), which letter gives an entirely wrong impression as to the attitude taken by the Yarmouth medical men in regard to consultations with the Institute medical officers.

Under ordinary circumstances we certainly do refuse to meet the medical officers of the Institute, because we consider they have behaved in a most unprofessional manner to the rest of the profession, but in any really urgent case we are individually prepared to render them help when called upon to do so. In the case of the genuine working-man club patient who is not even able to pay even low medical fees desiring a consultation we are prepared on dismissal of the Institute officer to take sole charge of the case and to treat the patient gratuitously if necessary. Had Dr. Ryley manifested as great an amount of zeal and interest for local medical organisation as his letter displays for general medical politics by attendance at the meetings of this society which he assisted to form he would not have brought this accusation against his professional brethren, but would have been well aware of the position taken by the society since its commencement, which his letter shows he is not. We further regret this, as we think, unnecessary zeal because at the time of writing his letter to THE LANCET we were in correspondence with him on that very point.

Whilst admitting that "boycotting" is not an ideal method of obtaining our ends we can see no other effective one so long as the General Medical Council, the colleges, and the universities hold aloof from taking any practical interest in matters which vitally concern the well-being of the general practitioner. We are at one with Dr. Ryley in his desire for a "central representative body," and as a society have made efforts (of which he is apparently ignorant) to attain that end, by sending a delegate to the recent Manchester Conference. The statement attributed by Dr. Ryley to the secretary with reference to London consultants is entirely erroneous, no such avowal having been made by him either at the last or any other meeting of the society. Enclosed, for your perusal or for publication, is the correspondence between Dr. Ryley and this society, and we shall be grateful for any comments you may care to make thereon.—I am, Sirs, yours faithfully,

W. E. WYLLYS, Honorary Secretary.

*** We have read the correspondence between the Great Yarmouth District Committee of the Incorporated Medical Practitioners' Association and Dr. James Ryley. It is at present incomplete, for no practical steps are to be taken by the association until a reply is received to its last letter from Dr. Ryley. We do not, therefore, publish the letters, but we may remark that reading them has left the impression on our

mind that Dr. Ryley ought to have no difficulty in remaining a member of the association without any sacrifice of his principles.—ED. L.

*To the Editors of* THE LANCET.

SIRS,—Dr. Ryley's letter in THE LANCET of August 25th (p. 628) will be read with regret by many members of the profession who have envied the Yarmouth men for the admirable way in which they combined in the day of trouble and have held together since. It is a proof that even the Yarmouth Association has at least one weak-kneed member—a fact which will give considerable satisfaction to the clubs which five years ago treated the local profession in a manner which Dr. Ryley mildly terms "ungracious." If the letter in your last number had simply been an indictment of the methods pursued by the Yarmouth Association I should not have interfered as the Yarmouth men I know are quite capable of defending themselves. But as the letter is an onslaught on the only methods by which any useful organisation can work, I trust you will allow me a little space.

Dr. Ryley's chief objection to his association seems to be that it *did something*. One must at once admit that it is not the usual thing for a medical organisation to act, and Dr. Ryley was probably hurt when he found the association acting instead of merely holding meetings and talking, as is the accepted custom in many such associations. If the Yarmouth Association had relied on talk about the dignity of the profession Dr. Ryley would doubtless have been still an uncomplaining member of the association. He complains that the association boycotted the imported medical men; he objects to its refusal to have dealings with patients so long as they are attended by the institute medical officers; and he protests against influence being brought to bear on consultants in order that they may be induced to back up the association. It would be interesting to hear what in Dr. Ryley's opinion the association should have done. I must confess that these things seem to me not only commendable, but the only things which the Yarmouth medical men could do. It would hardly be worth while forming an association unless something was to be done which could not be done by individuals. Will Dr. Ryley kindly explain? Does he think any good would have been done by simply protesting and then proceeding as if nothing had happened? Would he have the imported practitioners treated in the same way as the ordinary beginner is treated? Does he think that the public—whose opinion he seems to value more than that of his colleagues—would think more of the Yarmouth men if the latter had sat with folded hands after the treatment which Dr. Ryley himself calls ungracious? But after voicing his dissatisfaction with the Yarmouth plan of campaign Dr. Ryley proceeds to question the methods of medical organisations in general. Without in any way meaning to be offensive I must say that here Dr. Ryley falls into the customary professional cant. To my mind there is nothing more sickening than the repetition of the old old phrases by which we try to lead others to think, and to delude ourselves, that we as a profession are animated by motives of pure philanthropy and that the fee is a secondary and rather undignified detail. To listen to this cant—most rampant about Oct. 1st in the neighbourhood of medical schools—one might think that the members of the profession come from a moneyed class whose sole duty and pleasure it is to cultivate the virtues of altruism and charity. It is an offshoot of the same kind of cant which would lead us to believe that we as a profession are above the economic conditions which guide the conduct of other callings. I am as proud of my profession as most men. I know that as men with ordinary human feelings, brought into constant contact with suffering and hardship, we frequently ignore the monetary side of our relations with patients, just as other ordinary men with ordinary feelings would do in similar circumstances. But this kind of thing is a matter for each man to settle for himself as the circumstances arise, and I hold it to be wrong, misleading, and hypocritical to talk, as we too often do, as if the public had a right to expect to find a miracle of altruism in the person of every medical practitioner. This kind of talk has led to much misunderstanding, is pharisaical, and has become a professional cant.

It is a matter of observation that nearly all callings during the last 50 years have felt the necessity for combination. Combine or be exploited is the order of the day. It is equally a matter of common knowledge that those callings which have most thoroughly organised themselves have most improved their status and income. They have done this by the use of "trade union methods" to which Dr. Ryley objects so much when used by medical men. If he will explain what other methods are open to us he will confer a favour on the profession. What are the methods to which Dr. Ryley objects and which he believes are undignified when used by us? I suppose boycotting and the strike are the two most open to exception. As regards boycotting, this is a legitimate and legal method of showing disapproval. It is used on a larger or smaller scale by all callings and classes. Is it not usual for a medical man to refuse to meet or countenance another who conducts himself in an unprofessional manner? And surely what is proper and recognised in the individual cannot be heinous when done by a body. Dr. Ryley pities the public of Yarmouth who cannot have a member of the association unless they first give up the attendance of the institute medical officer, but this is simply carrying out the preliminary protest in a practical way. The effect of the protest would have been *nil* unless followed up in this manner. As for the strike everybody believes that in the case of working men it is sometimes inevitable. The trade unionist knows that it is not a weapon to be carelessly used, but is invaluable as a last resort. Why should medical working men, suffering, as they often do, from the injustice of organised bodies of the public, deprive themselves voluntarily of this weapon? and what substitute does the stickler for the "dignity" of the profession offer?

We must be practical. Individual patients may safely be left to individual practitioners, but when we deal with bodies of the public the situation demands organisation on our part. Experience has shown that disorganised medical men always get beaten by the organised friendly societies, for example. If we agree to organise we must use weapons which have been found useful by similar bodies, or find others. Dr. Ryley does not even suggest the existence of others. To those who find the idea of medical unionism strange and repugnant I would ask the following question. Do you believe that a man will be less skilful, less humane, less charitable, or less of a gentleman because he belongs to an organisation able and willing to protect him in the possession of his rights and privileges? Our professional dignity we can safely leave to look after itself, but one might fairly point out that dignity and strength are not incompatible. We are all in accord with Dr. Ryley's wish for a strong central means of co-ordinating and governing the various local organisations; but we must remember that it is by the formation of such bodies as the Yarmouth Association and the example they have set that the need for such a centre has been driven home to the profession. Even if we had such a body much would perforce be left to the good sense of the local practitioners, and Dr. Ryley would then, as now, be obliged in great measure to rely on the judgment of his colleagues, who have as much to lose and are presumably as jealous as he for the honour of the profession. I am, Sirs, yours faithfully,

Gateshead, August 27th, 1900. ALFRED COX.

## "THE CAUSE OF CARIES OF THE TEETH."

*To the Editors of* THE LANCET.

SIRS,—The Decay of Teeth Committee of the British Medical Association in their report to the council suggest among the causes that by the civilised methods of preparing food thorough mastication is rendered unnecessary and that this limitation of the action of the muscles of the jaw is further shown by atrophy of the jaw, as a consequence of which the teeth become overcrowded. These statements appear to only half meet the case. With bread made from roller-flour additional mastication is really necessary in order to obtain a large supply of saliva to promote digestion and it is quite possible that the low nutritive value of roller-flour is a great factor in atrophy of the jaw. To properly appreciate the difference in the nutritive value of roller-flour as compared with stone-made, it appears necessary to briefly consider the modes of manufacture. In old stone mills the wheat to be ground is fed in through a hole in the upper or running stone, when by reason of the dress or cut put into the surfaces of the stone, assisted by centrifugal force, the wheat becomes pulverised on its way to the periphery or skirt of the stones, whence it passes

through mechanical sifters and dressers and the coarse parts are separated from the flour. By this method all parts of the wheat grain are cut up more or less and the resulting flour contains particles of all parts.

In the modern invention, the roller-mill, the wheat is at first only rolled to smash it in order to separate the kernel from the husk and the germ, and the operation is repeated several times between fluted iron rollers until the object aimed at is obtained, and then the parts of the kernel pass on to be ground between smooth iron rolls. This rolling is succeeded by dressings in cylinders covered with silk, through which the flour made between the smooth rolls passes, and the rollings and dressings are repeated until all the flour is extracted and only the pollard is left. By this method only parts of the kernel are ground up and the resulting flour does not contain any particles of husk or germ. The husk, although very rich in lime salts, is very indigestible. The lime salts contained in the germ are easily assimilated. The germ is the vital part of the grain and acts very like a stomach for the young wheat plant, the diastase it contains converting the starch of the kernel into grape-sugar which helps to nourish the young plant. One part of the diastase contained in the wheat germ will convert a thousand parts of starch into grape-sugar. The starch in the dough must be gelatinised or scalded in order to obtain the full effects of the diastase upon it. The heat at which wheat-starch becomes gelatinised is 150·5° F. Thus when the dough is placed in the oven and the required heat is reached the starch-cells burst and the diastase acts upon it. After the heat of 180° F. has been reached the power of diastase ceases.

Since starch forms about 60 per cent. of wheaten flour the nutritive quality of bread is considerably lowered by removing the germs in roller-milling. It can be easily understood that if we get the dough at a point at which the starch is gelatinised, and at the same time have a certain amount of diastase intermingled with it that will convert a portion of the starch into grape-sugar, we have succeeded in obtaining a bread which will be easily digested. The bread made from flour ground in a roller-mill even if well masticated and swallowed with a good supply of saliva is not so easily digested and assimilated as when the flour is obtained from a stone mill.

As teeth are often the first part of the body to show signs of the effects of malnutrition, the removal of all parts of the wheat-germs from the roller-flour used to make the higher priced bread must have largely helped to cause much dental caries and atrophy of the jaws amongst the rich. The wheat-germs which the roller-miller has removed in making the flour for his higher-class customers are mixed with low-grade flour and made into cheap bread for the poor. The stone-made flour largely used to make the lower-priced bread contain particles of husk and the lime salts and diastase of the wheat-germ, and therefore is well adapted to help in the development of strong jaws and sound teeth. Bread made from roller flour from which the wheat germs have been removed being deficient in nutritive qualities appears to have considerably helped to cause atrophy of the jaw and the resulting defective teeth.—I am, Sirs, yours faithfully,

THOMAS G. READ, D.M.D. Harvard, L.D.S. R.C.S. Eng.

Cavendish-square, W., Sept. 3rd, 1900.

---

*To the Editors of* THE LANCET.

SIRS,—With reference to the letter from Mr. A. Berlyn of Cape Town, in THE LANCET of August 25th, in which he states that the natives of South Africa "live on nothing but soft pappy food," and yet carious teeth amongst them are the exception rather than the rule, it would be interesting to know for what period these African natives have subsisted on this soft diet. In the West Indies, where the negroes are all descendants of African slaves, a soft diet also prevails—a diet which has only of recent years been exchanged for a much coarser and harder one—but there the condition of the natives' teeth to-day is almost exactly opposite to that described by Mr. Berlyn.

There are, of course, exceptions, but the rule there is: white-looking teeth, which are freely attacked by caries, often not a sound molar or bicusbid at the age of puberty, and often the incisors broken down by the ravages of decay at a very early age. Suffering from toothache is very common; abscesses, accumulations of tartar, irregularities and malformations, pyorrhœa alveolaris, and indeed every kind of dental disorder can be commonly seen. The Africans who were imported into the West Indies over 62 years ago no doubt had teeth of the character of those described by Mr. Berlyn; what, then, has brought about this marked degeneration in so short a period? If I may be allowed to give an opinion without going into details I should attribute it to the change of diet and mode of living.

I am, Sirs, yours faithfully,

ERNEST STURRIDGE, D.D.S., L.D.S. Eng.

Wimpole-street, W., August 27th, 1900.

---

*To the Editors of* THE LANCET.

SIRS,—In THE LANCET of August 25th I notice that Mr. Berlyn of Cape Town would like explained how the fact which he put forward could be reconciled with the theory I advanced and which was so generously supported by Dr. Harry Campbell. Mr. Berlyn says: "The great majority of South African natives live on nothing but soft pappy food, which consists of a very soft porridge made from ground mealies or Indian corn ..... and yet carious teeth among natives are the exception rather than the rule." I should like to point out that this porridge is made of Indian corn which is bruised or crushed, and there is no attempt made to eliminate the coarse and fibrous part such as is done by the elaborate processes which wheat, for example, undergoes in the manufacture of flour. As far, therefore, as this, the staple article of diet, is concerned the Kaffir does *not* eliminate the fibrous part from the natural foodstuff. According to my views such a food is not liable to lodge in the crevices of, and between, the teeth, and the act of masticating it tends to keep the teeth free from fermentable matter. I bruised and crushed some Indian corn first with a hammer and then with pestle and mortar after having soaked it in water for 24 hours so as to try to make it soft. I then boiled it for an hour. On examining I found the more or less powdered part mixed with a fine tough transparent scale which naturally surrounds the corn grains. I then added a little salt and ate the porridge thus prepared. It required a very considerable amount of mastication, much more than does coarse brown bread.

I think, however, Mr. Berlyn is hardly correct in saying that the majority of the natives "live on nothing but soft pappy food," as the following extract from Ratzel's "History of Mankind," vol. ii., p. 433, would indicate. "Thus the Kaffir gets his food about equally from his fields and from his herds. The basis of it is sour milk, *amasi*, and bruised maize, *amabele*, or millet, *umbla*. Meat is eaten alike boiled or roast and is much relished by the natives. According to Gardiner's estimate four or five can manage to eat up a whole ox—entrails, sinews, and all—in a day and a half." The teeth are often much worn from the very considerable amount of mastication which they perform, and, as will be observed from their eating the sinews of an ox, they are not particularly addicted to eliminating the fibrous part from their foodstuffs. These people are very free from dental caries and are an interesting confirmation of the theory that "the cause of the prevalence of dental caries is that the natural foodstuffs [of the civilised] are to a large extent ridded of their accompanying fibrous parts and prepared and consumed in a manner which renders them liable to lodge and undergo acid fermentation in the mouth," &c.

I am, Sirs, yours faithfully,

Kingston-on-Thames, August 28th, 1900. J. SIM WALLACE.

---

*To the Editors of* THE LANCET.

SIRS,—If Mr. A. Berlyn's assertion be correct that "the great majority of South African natives live on nothing but soft pappy food," and if it can be shown that they do not habitually chew hard things of any kind, then the view I hold, in common with Dr. J. Sim Wallace, falls to the ground. That, however, these natives do use their muscles of mastication far more than civilised peoples seems to me to be proved by the perfect development of their jaws and muscles of mastication. Nothing is more certain than that if these structures are not adequately used they will not develop properly. I am, Sirs, yours faithfully,

Wimpole-street, W., August 25th, 1900. HARRY CAMPBELL.

---

## "THE COVENTRY DISPENSARY."

*To the Editors of* THE LANCET.

SIRS,—In the agitation against this institution which has now been raging, at intervals, for eight years a persistent

attempt has been made to obscure the real issue by "drawing a red herring across the path," to wit, the registered friendly societies. In a communication which I drew up for the Council of the British Medical Association during the presidency of Dr. Saundby, just prior to the annual meeting at Edinburgh, I made the following statement regarding these societies: "It is true that some of the outside medical men hold these appointments, but we have never asked the dispensary committee to apply a wage-limit to these selected members, as it was felt that the time was not yet ripe to attack these societies. Moreover, the outside doctors fear to attempt any reform in this direction as the dispensary blocks the way, and, as has repeatedly occurred, it immediately absorbs at a lower rate of payment any society which may be relinquished." I do not wish to retrace further the thread of the argument in this controversy, but merely to emphasise the fact that these societies have always been regarded as distinct combinations, and I have yet to learn that any official censure has been passed on men holding these appointments by the medical press, the medical societies, or the British Medical Association. It is no doubt true that great abuses exist in the terms of their contract with the profession, but being registered by Act of Parliament they present peculiar difficulties, and in the opinion of some the solution of these difficulties involves some knotty points of law. Dr. Saundby asks us to "formulate the reforms we are prepared to accept as satisfactory." Accepting the challenge, we hope soon to give the consultants of Birmingham the opportunity of deciding whether in the future they are prepared to uphold the honour of their profession or the interests of their pocket. In the first place, we must insist on some reasonable wage limit whereby it may become impossible for the rich to monopolise an institution founded to meet the necessities of the poor or the wage-earning section of the community. This must be not only prospective but retrospective—not necessarily to apply to members of registered friendly societies. We insist on the rule being abolished that the medical officers should not hold consultations with anyone outside their staff except those from other towns. We object to the system of touting encouraged by the rule that anyone can join even when ill "if he or she can procure two healthy persons to enter at the same time and pay one year's subscription in advance." We also strongly object to a condition of things whereby the medical profession is exploited for pecuniary gain. This is proved from the fact that surplus funds are not all divided up amongst the profession, but money has been invested on mortgage, and property in addition purchased. We resent the idea of professional men administering medical relief in accordance with the dictates of a lay committee controlling funds collected from the members or left to the institution by philanthropists. The medical men have no control over the disposal of these funds, which may be diverted to any purpose. Their position is somewhat analogous to that of the practitioner who covers an unqualified assistant—i.e., an individual who receives money by virtue of his connexion with a registered practitioner of medicine. We propose to ask the members of the Birmingham Branch of the British Medical Association to refuse these men professional recognition until some reasonable reforms are introduced. If they carry such a resolution the power of this lay committee is paralysed; reforms must then come which will be for the interests of the profession in general and the staff of the institution in particular.

I am, Sirs, yours faithfully,

Coventry, Sept. 3rd, 1900. W. RICHARDSON RICE, M.D. Dub.

*To the Editors of* THE LANCET.

SIRS,—I am sorry to trouble you again, but Dr. Phillips's letter implies that I did not state the truth when I said that I had not been asked to support the profession in either town against any individuals nor had such a request been brought before any of our medical societies. It is quite true, as Dr. Phillips says, that some years ago he and Mr. Faulder White called upon me about the Coventry Provident Dispensary, but it was to ask my assistance as President of the Council of the British Medical Association and in that capacity I rendered him all the help in my power. It is also true that the matter of the Provident Dispensary was referred by the Council of the British Medical Association to the Ethical Committee of the Birmingham and Midland Counties Branch, but that committee sits apart and does not report its proceedings to the branch. The committee reported back to the Ethical Committee of the Council of the Association and upon that report the Council of the Association passed its condemnatory resolution. The Birmingham consultants have been accused of having failed to render assistance to the medical profession in Coventry and what I have said I now repeat: that the medical profession in Birmingham has never failed to render any assistance asked for by the medical profession in Coventry and that Dr. Phillips's letter is uncandid and unfair, because when he did ask my assistance some years ago, not as a consultant in Birmingham, but as President of the Council of the British Association, I did all in my power to help him, and the Ethical Committee of the Birmingham Branch also when referred to from London did its share of the work. I cannot see that it advances any cause to make charges that are so easily proved to be false and that cause not unnatural irritation in the persons who are the objects of them.

I am, Sirs, yours faithfully,

ROBERT SAUNDBY.

Great Charles-street, Birmingham, August 28th, 1900.

*To the Editors of* THE LANCET.

SIRS, In your note following the correspondence *re* "The Coventry Dispensary" you state: "Our aims are to obtain a decrease in hospital abuse and a cessation of the sweating tactics employed in the management of many medical aid associations." Would your, Sirs, lend an ear to one of your readers in Bethnal-green? Here we have a powerful organisation, born and fostered by the Church, which is ruining the incomes of practitioners in the neighbourhood. I refer to the medical missions. In my own sphere tradesmen, mechanics, and men earning good wages accept the aid of the medical mission in lieu of the general practitioner. An attendance at the church is all that is necessary for a visit from the medical man or nurse, and a confinement at 4*s.* 6*d.*, with nourishment thrown in, is a fee with which no respectable practitioner would care to compete.

I am, Sirs, yours faithfully,

PERCIVAL ALLEN.

Bethnal-green-road, London, E., Sept. 3rd, 1900.

## TREATMENT OF HÆMORRHAGE BY THE SUBCUTANEOUS INJECTION OF SOLUTION OF GELATIN.

*To the Editors of* THE LANCET.

SIRS,—I have had occasion to make use of this treatment on three occasions and the success has been striking, as the following reports will show. The method adopted was as follows. A solution was made of 200 grains of sheet gelatin in two pints of distilled water containing 60 grains of "Cerebos" salt. This was clarified with egg albumen, boiled, filtered through cotton wool, made up to two pints, and boiled again for 15 minutes, and then bottled in a sterilised bottle whilst at boiling heat, well corked, and kept for use. At each injection six ounces of this were injected at a temperature of 103° F. into the cellular tissue of the buttock, with the usual precautions as to asepsis, such as boiling the syringe and using collodion to the puncture. In Case 3 alone did any inconvenience result to the patient from the injection, but neither induration nor pain at the site of injection nor any constitutional disturbance were noticed in the others.

CASE 1. *Hæmoptysis.*—A married woman, aged 72 years, was greatly depressed subsequently to the shock induced by the sudden death of her husband a fortnight previously. On July 1st she developed gout of the right foot, with heat, redness, swelling, and pain over the dorsum. She was treated with 15 grains each of guaiacum powder, potassium bitartrate, and precipitated sulphur every night, and a dietary of good light food, as fish and broths, with plenty of fresh lemonade and fruit. The gout disappeared, but on July 4th she developed some œdema over the front of the chest wall, including an area as large as a dessert plate starting from the lower part of the sternum as a centre. At the same time great irritation of the fauces caused an ever-recurring dry cough which prevented sleep. The fauces and larynx were examined with negative results except that the left side of the pharynx was occupied by a distinct pulsation and this, after examination, was attributed to anatomical variation of the internal carotid; the œdema of the chest was thought to be due to depression

partly consequent on shock, gout treatment, and sleeplessness. From the 4th to the 14th she remained in bed with frequent change of position. She was to have got up on the 15th. On the morning of the 15th she had an attack of hæmoptysis at 5 A.M. and brought up two and a half ounces of frothy bright blood having an alkaline reaction. This was apparently attributable to the coughing having caused a rupture of some atheromatous vessel. The usual treatment by solution of chloride of calcium, hazeline and hydrastis by the mouth, and hypodermic injection of ergotinin, with an ice-bag on the upper part of the left chest, was adopted. The hæmoptysis recurred six times on the 15th, from the 15th to the 16th four times, and on the morning of the 17th it recurred every 15 minutes; on each occasion one ounce was brought up. Hæmorrhage was evidently continuously going on and when it had accumulated to the extent of an ounce caused irritation and was coughed up. At 10 A.M. on the 17th, during hæmoptysis, the gelatin was injected. The hæmoptysis ceased and did not recur and the patient made an uneventful recovery and is now at the seaside doing well and has not had any further trouble.

CASE 2. *Post partum flooding.*—A multipara, aged 27 years, was delivered at full term of a fœtus and placenta on July 21st. At the time of delivery she was alone, although I was but 10 minutes in reaching her house after being called at 5.20 A.M. The uterus was distended to three inches above the umbilicus with fluid blood and she was still losing. I at once emptied the uterus and with a flushing curette with water at 115° F. the whole surface of the uterus was passed over; a large rent in the perineum was brought together with four deep sutures. As the hæmorrhage continued a hypodermic injection of ergotin and strychnine was given, the uterus was well contracted, and the pulse was fairly good and about 90°. Dr. R. R. Law, of Sidcup, now came to my help, and took charge of the uterus during my absence; in half an hour the gelatin solution, &c., was ready; the patient was still losing freely, her lips were blue, she was exsanguine and restless, and the pulse was thready. The gelatin was injected into the right buttock and the hæmorrhage ceased at once and did not recur.

CASE 3.—The patient, a woman, aged 57 years, 5-para, had suffered from prolapse for some 20 years. During the last year she had suffered from very grave periodical losses due to fungous endometritis, which was in its turn due to the chronic uterine congestion dependent on the prolapse. The uterus was curretted with a view to diagnosis. The hæmorrhage was treated by the usual medicaments and by packing the uterus with ribbon iodoform gauze and vaginal tampons soaked in liquor hamamelidis. The metrorrhagia became more profuse with each attack, recurring every five to seven weeks, and I finally advised vaginal hysterectomy. I did not treat the patient at her last metrorrhagic loss; she consulted another medical man who made weekly applications of nitric acid and in the intervals used the "coton styptique." During the entire month the hæmorrhage continued and after the last application it was more free than before. The patient was advised to undergo vaginal hysterectomy and was sent back to me. She was seen on August 15th, 1900, and had been losing every day as described. I injected five ounces of 1·5 per cent. solution of gelatin into the buttock and this caused much pain and faintness, the temperature went up to 101·4° F. that evening and the pains prevented sleep during that night. From August 16th onwards the patient has been carried into the garden each day, and until now she has not had a trace of hæmorrhage. Every day she is visibly recovering her usual tone and health in a way that will assist her in bearing the shock of the projected hysterectomy.

The difficulty of having this remedy at hand is best met by making a concentrated solution of 200 grains of gelatin in a quarter of a pint of distilled water and one ounce of salt, putting it up in half-ounce bottles, each of which when diluted, re-sterilised, and filtered makes a five-ounce injection, enough for one dose.

This remedy is more or less empirical, but it is easy to assume that hæmorrhage in each of the above cases was due to some deficiency in the blood, induced by debilitating strain of various kinds removing from the blood some substance essential to coagulability, and that the gelatin injection, quickly absorbed, presented the foundation or deputy fibrinogen rendering coagulation once again possible. It should be remembered that the inducement of coagulation is so positive a property of this treatment that it would appear that there is real danger of inducing thrombosis in the event of too strong a solution or too large a dose.

I am, Sirs, yours faithfully,
G. W. DAVIS, M.D., B.S. Durh., L.R.C.P. Lond., M.R.C.S. Eng.
Sidcup, Kent, August 22nd, 1900.

## DUOTAL IN OSTEO-ARTHRITIS.

*To the Editors of* THE LANCET.

SIRS,—During the last nine months I have been prescribing duotal (carbonate of guaiacol) in cases of both acute and chronic osteo-arthritis with markedly good results. Duotal is a white powder, tasteless, odourless, is said to be non-poisonous, is insoluble in water, and therefore is best prescribed in capsules or wafers. It does not interfere with the digestive functions and is split up in the intestines into carbonic acid and guaiacol. There the latter becomes absorbed into the system and can afterwards be traced in the urine. It produces no depression, is free from the disagreeable irritative effects of guaiacol, and it seems to stimulate the appetite and facilitate assimilation. As to the dose, it is better to begin with the minimum and gradually increase to the maximum. I usually commence by ordering five grains every four hours or three times daily, according as the disease is acute or chronic. On the second or third day I increase the dose to 10 grains, and after the first week I give from 15 to 20 grains three times daily. In the acute form of the disease it relieves pain, reduces the temperature, and diminishes the swelling of the joints, but in the chronic affection, although it relieves pain and stiffness, I cannot say that it effects any diminution of the bony enlargements. I have thought, however, that in some cases in which I have prescribed it for a few weeks it seems to bring the progress of the malady to a standstill, at least for a time. In those incipient cases of the chronic form of the disease which exhibit peripheral nerve-pains its effect in relieving pain is very noteworthy. I have found that this is lessened in from 24 to 48 hours, and in most patients has entirely disappeared in the course of a week. When the early signs are those of stiffness of the neck together with tenderness over the spines of the cervical vertebræ or of stiffness of the jaw its effects are equally good. It is most useful also in those cases of the chronic malady in which the early symptoms are pains in various parts of the body, some referred to the joints and some to the muscles, such as the inner side of the wrist or the ball of the thumb, numbness and tingling of the extremities, and some stiffness of the joints on movement. In these cases I have found that five or 10 grains of duotal taken three times a day for 10 days or a fortnight relieve these symptoms. Now, as it is these early cases of the disease that one may reasonably hope to cope with it is very important, after having obtained favourable results from the action of duotal, to improve the general health by other well-known drugs and to lay down the strictest injunctions as to diet and hygienic measures, and where possible to order a yearly trip to Aix-les-Bains for a few years; for it is an undoubted fact that many cases of osteo-arthritis, not only those exhibiting early manifestations of the affection but also much more advanced cases, maintain their ground for years under suitable treatment.

In prescribing duotal in the acute form of osteo-arthritis I have been careful to differentiate it from allied diseases. From acute or even sub-acute rheumatism this differentiation can generally be effected by noting the principal points which distinguish it from the latter disease; positively, by the fact that the articular swellings (of the larger joints at least) are more circumscribed, by the special susceptibility of the smaller peripheral joints to become involved, and by the progressive character and great obstinacy of the symptoms; negatively, by the absence of tonsillitis, of cardiac lesions, and of profuse acid sweats. From an acute attack of gout it may be separated by the length of the paroxysm, by the want of periodicity, and oftentimes by the large and small joints being indiscriminately invaded in its development, and by there being no particular susceptibility to the invasion of the metatarso-phalangeal joint of the great toe, although it must not be forgotten that these joints are also frequently involved in osteo-arthritis.

The following cases will serve to illustrate the exhibition of the drug:—

CASE 1.—The patient was a married lady, aged 38 years,

she had one child, aged 16 years, a male. Her mother was dead and was said to have been tuberculous. Her father suffered from gout; she had one brother and sister, who were believed to be quite healthy. The patient was anæmic, otherwise she was well nourished; her complexion was fair. The present illness commenced on Jan. 9th, 1900, with slight feverishness and tenderness in both wrists. In a few days other joints became painful, tender, and swollen; first the ankles, then the fingers and elbows. From Jan. 11th to the 14th the temperature curve varied from 101° to 102° F., morning and evening respectively. On the 13th five grains of duotal were ordered every four hours. On the 15th the morning temperature was 100° and the evening temperature was 100·4°. On the 16th the dose of duotal was increased to eight grains, and the temperature on the 17th was 99° in the morning and 99·6° in the evening. The temperature now varied little till the 19th when after 10-grain doses of the drug it became normal in the morning and 90° in the evening. On the 21st the temperature was normal morning and evening, and it did not again rise. By this date also the pain and tenderness had nearly disappeared, but there was still some swelling of the joints, especially those of the hands, and stiffness was complained of in all the affected joints. This swelling and stiffness continued in a smaller degree in all the joints for another two weeks, during which time the patient was taking 10 grains of duotal three times a day. After this the stiffness and swelling became daily much less marked and the drug was discontinued after having been taken for four weeks. Treatment to improve the general health was now adopted and the patient was advised to go to Aix-les-Bains at the end of May.

In Case 2, where an acute attack occurred in a patient who had been suffering from well-marked chronic manifestations of the disease in both hands, I found the drug very valuable. In this patient, a female, single, aged 49 years, anæmic, who had a dark complexion and was a hard worker, the temperature varied between 100° and 101·2° F. The knees and shoulders were very painful with little or no swelling, but the hands became swollen and painful, and stiffness was much complained of. I commenced with five grains of duotal every four hours. The following morning the temperature was 99° and the pain was less. I now ordered 10 grains three times a day for the next eight days. The temperature became normal and the pain and stiffness became less in two days. At the end of eight days the patient had lost all pain and stiffness in the shoulders and knees, and the hands were apparently in the same state as before the acute attack supervened. She continued the drug for another week and then found that she could use her hands with more ease and comfort.

CASE 3.—The patient was a man, aged 58 years, a postman; he was anæmic and had a dark complexion. He had been suffering for some years from the fully developed affection in its most chronic form. The malady was especially marked in the hands, where the well-known flexions were very typical. He complained much of the hip and knee joints, and had great difficulty in walking. I prescribed seven grains of duotal three times a day for two days and then increased the dose to 10 grains for a fortnight. At the expiration of this time there was an improvement, as he could walk with less difficulty. For another fortnight he continued the same dose of the drug and could then walk fairly comfortably, but there was much stiffness in all his affected joints after a night's rest. I now gave him 15 grains three times a day for a week and then found he had comparatively little difficulty in getting about, and he has maintained his ground for some months.

I am, Sirs, yours faithfully,

W. H. RUSSELL FORSBROOK, M.D. Lond.

Buckingham Palace road, S.W., August 20th, 1900.

## "THE PROTECTION OF PARTURIENT WOMEN AND NEWLY-BORN CHILDREN."

*To the Editors of* THE LANCET.

SIRS,—The Manchester Medical Guild are to be congratulated upon the attitude towards the midwives question which, at the instigation of Mr. G. H. Broadbent (*vide* THE LANCET of August 18th, p. 560), they have taken up; for, little as we may like grandmotherly legislation, this scheme is based upon the sound principle that every parturient woman should have fully qualified medical attendance in her labour. And it constitutes a definite policy in opposition to the registration of midwives, which mere blank negation did not. In response to Mr. Broadbent's invitation I would suggest the omission of the "public obstetricians" from the scheme. To the public their appointment will appear cumbrous and unnecessary since the Poor-law medical officers are already appointed to attend to this very thing; the patients will, as now, shrink from engaging an arbitrarily appointed State-paid officer; and thirdly, the functions of the public vaccinators under the new Act have caused so much friction that the profession will strongly deprecate the appointment of officers whose functions would interfere even more with private practice. The alternative I suggest is that a parturient woman whose claim for State (or rate) aid is made good should be free to engage whichever local practitioner, being registered, she may induce to attend her for the fee guaranteed by the State or the board of guardians. It is of the greatest importance that a patient should choose his or her own medical attendant. That is why we are registered.

I am, Sirs, yours faithfully,

Plaistow, E., August 22nd, 1900. P. NAPIER JONES.

## PLASMON.

*To the Editors of* THE LANCET.

SIRS,—In a short report, or rather notice, of a paper read by me at the British Medical Association at Ipswich which was published in THE LANCET of August 18th (p. 515), I was quoted as having said that the preparation of plasmon was a costly one. This is a reporter's error. One of the great advantages of plasmon is that both the material from which it is made and the process of manufacture are exceedingly cheap.—I am, Sirs, yours faithfully,

London, August 30th, 1900. F. W. TUNNICLIFFE.

## "A RIDE FROM LONDON TO EDINBURGH AND BACK ON A TRICYCLE BY A VEGETARIAN IN HIS SEVENTY-EIGHTH YEAR."

*To the Editors of* THE LANCET.

SIRS,—As an addendum to my letter in THE LANCET of August 25th (p. 629) the following particulars may be of interest. I did not eat any flesh food in any shape nor did I even eat eggs. Neither did I touch wine, beer, spirits, or tobacco. I ate whole-meal bread and biscuits when I could get them and a little cheese, but not much. During the first 15 days I never sat down to a table for dinner. I ate my food riding or on a bank by the roadside—some bread-and-cheese with a tomato or banana or both, or some bread and a bit of chocolate. Now and then I got a glass of milk, but I think I felt better without it. On only about 10 of the 31 days did I have any vegetables and only on about seven days a little pudding with or without fruit. My breakfast was mostly weak tea or cocoa-and-milk with bread-and-butter and marmalade or jam. My evening meal was mostly cocoa-and-milk with bread-and-butter and sometimes marmalade. On two or three occasions I had some porridge and once some bread-and-milk. I did not eat at stated times but would munch (my teeth have all disappeared) some bread or biscuit with some sweets or chocolate as I rode along. I did not drink a great deal as a rule during the day, and I have ridden all day without wiping my face, so free was I from sweating, but I drank water sometimes pretty freely in the night. I always took a jug of boiled water to my bedroom and frequently, after my first sleep of about four hours—after which I generally felt quite refreshed—I would munch some biscuit and perhaps some chocolate and drink water as I felt to need it. Then, after reading and thinking for a time I would have another sleep. I did not have any aches or pains nor any signs of distress during the whole time I was away.

My object in taking this ride was to satisfy myself by personal experience that good health and a full measure of vigour can be maintained under total abstinence from flesh, alcohol, and tobacco, and that, too, with such an amount of exercise as was requisite for a considerable effort. The lesson derivable from my experience seems to be that if we fed ourselves more thriftily and lived on simpler food we should enjoy our lives more completely and retain our activity for a longer period.

I am, Sirs, yours faithfully,

C. J. HARRIS, M.R.C.S. Eng., &c.

Kilburn Priory, N.W., Sept. 1st, 1900.

# NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

*Increase of Plague.—Inoculation against Plague.—The Pasteur Institute for India.—Health of Bombay City.—Birth-rate in the Punjaub.—Malaria and Water-supply.*

PLAGUE has reappeared at Belgaum, Poona, and Mysore. The plague deaths for the whole of India show a rise, Calcutta reporting 89, Mysore 67, Bombay city 58, Bombay district 45, Bengal districts 23, and Madras province three, making a total of 285. Private information is to the effect that plague is much more prevalent at some of these places than is reported. The continuance of plague in Calcutta with from 50 to 100 deaths every week is very serious. The general mortality of this city is 7 per 1000 per annum above the normal and the excess is not entirely accounted for by the plague. In the absence of any other explanation it is probable that there are more plague deaths than come to the notice of the authorities. The returns for the city of Bombay are extraordinary. For the week ending August 7th there were 1499 deaths, or 834 more than the average for the corresponding period of the preceding five years, the rate of mortality being 92·07 per 1000. There were 354 deaths from cholera and the number of deaths attributed to plague, as mentioned above, seems too small to be correct. For the month of July there were 3147 more deaths than during July of last year. Cholera exists not only in Bombay but in Madura and in the city of Nagur. Owing to plague existing at Hong-Kong all officers, men, and camp-followers proceeding to China have had the option of being inoculated with Haffkine's fluid before leaving their stations.

The Pasteur Institute at Kasauli was opened on August 9th, and 31 persons are now under treatment—namely, one British officer, 16 British soldiers, six sepoys, and eight other natives. The director is Major Semple, R.A.M.C., who was assistant professor of hygiene at Netley, and who visited Paris for the special purpose of studying the anti-rabic treatment. It is hoped that local organisations will arrange to pay the necessary expenses for the poor. The treatment will be entirely gratuitous, but as no hospital accommodation is required patients will have to make their own arrangements for board and lodging. Excellent accommodation for all classes is said to be procurable in Kasauli. It is understood that the Government of India will pay to the institution about Rs. 800 per month for the next three years. The institution also possesses Rs. 75,000 in Government notes, producing about Rs. 220 per month. The income, however, is not sufficient to meet all the expenses, so it is hoped that the public also will subscribe. Before it was opened the Government used to send European patients a three weeks' journey to Paris. The credit of its establishment rests largely with Surgeon-General Taylor, who took up the matter with great spirit in the interests of the British soldier. The anti-vivisectionists are now indulging in declamatory opposition to it. They assembled at Delhi and condemned the institution as being "repugnant to the feeiings and sentiments and to the tenets of every religion" in the country. They also appealed to the Viceroy to withdraw Government patronage from the institution and to prohibit vivisectional experiments either for the manufacture of "Pasteurian serum" or for any bacteriological purpose.

The quarterly report of the health officer of the city of Bombay refers to the large influx of destitute people from the country districts. The death-rate has been 151 5 per 1000 per annum. Dr. Weir complains of the unauthorised terms "Bombay fever" and typho-remittent fever," which are probably forms either of typhoid fever, Malta fever, or relapsing fever. He says that the water-supply "although impure from vegetable *débris* gave better results bacteriologically than was expected. The colonies were somewhat in excess, but pathogenic organisms were absent." The birth-rate was low, but the increase in the number of births points to an increased population. The proportion of males to females by the last census was as 170·6 to 100.

The extraordinary increase in the number of births in the Punjaub for 1899 beats all records. The increase amounted to 152,132, and the birth-rate reached 43·4 per 1000. The death-rate at the same time was 29·57. In the Jullunder, Ludhiana, and Amritsar districts there was an excess of deaths among females under one year old, a fact which raises a strong suspicion of the continued practice of female infanticide. For the suppression of this crime it is proposed to substitute medical supervision for police agency as an experimental measure in certain villages of the Jullunder district.

An inquiry has been held regarding the health of the riparian municipalities to the north of Calcutta and to the east of the river Hooghly, and the report was published not long ago. In his investigations Captain Rogers, I.M.S., had the subject of malaria particularly in view. To test for the amount of malaria a certain number of people, including children, were examined for enlarged spleens on the ground that "the percentage of a population who suffer from enlargement of this organ may be safely taken as the best practical indication of the degree to which the inhabitants are affected by this scourge of Lower Bengal." Precautions were taken to obtain a fair average of the various populations, and about half the persons examined were children. The enlarged-spleen rate was found to vary considerably. In order to explain these differences inquiries were instituted into the waterlogging of the soil, the water-level, the rainfall, and the water-supply. The enlarged-spleen rate was found to be much lower in places situated on the east bank of the Hooghly to the north of Calcutta than in those further to the east. In the more eastern areas the enlarged-spleen rate was 50 per cent., which is considered as approximately the normal figure for that part of the country. An exception, however, was found to exist in an extremely low-lying and waterlogged area which nevertheless had a comparatively small spleen rate. This area was constituted by the municipality of Maniktola, which had a good filtered water-supply. Again, it was found that Cossipore-Chitpur, which had the lowest rate of all, had the double advantage of a filtered water-supply and a situation on the east bank of the Hooghly. Captain Rogers concluded that as certain places equally waterlogged differed in the amount of their malarial infection there must be some other factor to account for the difference and that this was certainly not the absence of the malarial mosquito, because in the least affected area the anopheles were found more widespread than in any other part. The only possible factor he could find was the water-supply, for the two municipalities where the enlarged-spleen rate was low, although the soil was waterlogged and the anopheles abundant, were the only ones which had a filtered water-supply from the source as Calcutta itself. Among drinkers of river water the enlarged-spleen rate is nearly double, and among drinkers of tank water it is nearly treble that which is found among drinkers of filtered water.

August 16th.

# PLAGUE IN AUSTRALIA.

(FROM A SPECIAL CORRESPONDENT.)

THE returns of plague in Sydney for the week ending July 21st are as follows: remaining at the beginning of the week, 51; admitted, two; discharged, four; died, none; remaining at the end of the week, 49. The totals up to the end of the week are as follows: cases, 302; deaths, 101; recoveries, 152; "contacts" isolated, 1702; "contacts" remaining, 26; cases among "contacts," seven. The above figures include Chinese, of whom 10 were admitted with eight deaths, all the other patients being whites.

The returns of plague in Sydney for the week ending July 28th are as follows: remaining at the beginning of the week, 49; admitted, none; discharged, 14; died, one; remaining at the end of the week, 34.

The death was that of a patient admitted as far back as April 27th and was only indirectly due to plague. No case has occurred since July 17th. It seems that the epidemic is now over for this time, and, great and embarrassing as popular excitement was during the earlier three or four months, the complete cessation of public interest and alarm may be judged of from the fact that during last week a charitable fête was successfully held in the grounds of a mansion from which a case of plague was removed not more than six weeks ago. The committee had not even thought it worth while to inquire whether this proceeding was free from danger.

Clean bills of health are now issued endorsed with the late and scattered cases which have occurred since the 10 days' interval. The latest of the two recorded above was isolated on July 17th.

July 30th.

## MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

*Precautions against the Plague.*

AT the meeting of the Manchester Port Sanitary Authority held yesterday in the town-hall Dr. J. H. Crocker, the medical officer, presented a report dealing with the outbreak of plague in Glasgow and the measures adopted for preventing its introduction to Manchester. In July a medical inspector from the Local Government Board visited the port and approved of the measures then in use, but since his visit further precautions have been taken. An additional inspector is now at Eastham and inquiries are made of every ship which enters the canal. If a case of sickness is reported a telephonic message is sent to the medical officer and a medical inspection is made before the ship goes into dock. The other inspector visits the ships within the port, inquiring as to any sickness, inspects the vessels as to sanitary conditions, and sends daily reports to the medical officer, who also makes frequent visits of inspection. All the vessels from Glasgow are boarded at Mode Wheel and inquiries made as to any sickness. The names and addresses of all who leave the ships while in port are taken and filed for reference. Foreign vessels bound for Manchester are boarded by the Customs officers at Liverpool and if any cases of sickness are reported the chief officer of the Liverpool Port Sanitary Authority is communicated with. If the disease turns out to be plague, cholera, yellow fever, or small-pox the case is removed at Liverpool. If a case of plague is known to be on any foreign vessel bound for Manchester a medical inspection of all on board would take place. And if a vessel should reach Manchester with a case of plague on board the port medical officer would have power to remain on board and to order her return to Liverpool, where she and all on board would be handed over to the Liverpool medical officer. This power arose from the fact that when the order of the authority was made it was found that Manchester was not suitable for a quarantine station, which therefore was placed at Liverpool. If necessary an additional medical officer to assist Dr. Crocker temporarily may be appointed, for, as the chairman said, he "could not be engaged night and day." These arrangements seem well calculated to protect Manchester from attacks by sea, but no provision has yet been made against the possible introduction of plague in any other way. As one of the local papers says, the infection causing the terrible outbreak of plague at the village of Eyam, in Derbyshire, in 1666—still kept in lively remembrance—was found to have been brought in a bale of cloth sent from London. However, the people here need not feel any apprehension, for it may be considered quite certain that ceaseless vigilance is exercised and that if a case should arise all possible precautions will be taken to prevent the spread of the disease.

*Manchester Sewage Schemes.*

At the meeting of the Manchester City Council to be held to-morrow an important question is to be discussed and possibly decided on—namely, whether the sewage scheme recommended by the experts shall be adopted or that enjoined by the Local Government Board. The former is estimated to cost £337,713 and the latter £487,283. Each is based on preliminary sedimentation and anaerobic bacterial action in tanks, followed by aerobic treatment in contact beds. The difference results from the requirements of the Board as to the extent of the contact beds and in its insistance on the provision of 213 acres of land at Carrington and Flixton, necessitating the construction of a conduit. The scheme of the Board might be proceeded with at once, while the other would involve delay and the need for Parliamentary sanction. The scheme of the Board, though more costly to begin with, would leave some room for extension and there is no likelihood that Manchester will cease to grow for some time to come.

*"Faith Cures" at Oldham.*

It is not always quite clear whether "faith" or disbelief in "doctors" is the motive power influencing such people as the poor woman whose death was the subject of a coroner's inquest at Oldham on August 30th. The husband in his evidence said that his wife complained of feeling unwell on the Saturday but refused medical attendance as she was a "member of the Berachah Mission," whatever that may be, "and they did not believe in doctors." She was found dead in bed on the Wednesday. Her husband went on to say that his sect "believe that faith will cure them. ..... They reckon that the Lord will heal their wounds without a doctor being in attendance." As a rule the working-class people of Oldham are shrewd and sensible according to their lights, but they may be pronounced somewhat short of general culture and a prey to divers fancies and superstitions. The verdict was "Death from natural causes."

*Anthrax in Cheshire.*

Anthrax has broken out at a farm at Cuddington, near Northwich, and the sale of milk has been stopped. At the meeting of the Northwich Rural District Council on August 30th a question was asked as to how it was that the council had been notified in the matter when they had no power to deal with it. Mr. H. E. Gough, the medical officer of health, said: "We have a voice in the distribution of milk." The Agricultural Board deal with the matter and the chief constable is responsible. There seemed a disposition on the part of some members to demur to the stoppage of the whole of the milk from a farm because a single cow had the disease and had been killed, but Mr. Gough said it was laid down that no milk was to be sold until the veterinary surgeon was satisfied that there was no danger of infection.

Sept. 4th.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

*Plague in Foreign Ports: Sanitary Precautions in Liverpool.*

THE medical officer of health has officially notified medical men throughout the city that, owing to the presence of plague in foreign ports, a careful inspection of vessels from suspected ports is now taking place. He emphasises the fact that infected persons apparently in health on arrival may develop illness after landing. It is, therefore, desirable that special attention should be paid to seafaring persons coming under notice in early stages of illness. It will be remembered that a short time ago an inspector from the Local Government Board visited the port of Liverpool in regard to the precautions taken against the plague, and he expressed his approval of the existing arrangements. Needless to say the damage to the commerce of Liverpool, should an epidemic of plague gain ground, would be considerable.

*Asylum Accommodation in Lancashire.*

The difficulty of providing accommodation for lunatics in the Lancashire asylums is gradually disappearing. From the proceedings of the recent quarterly meeting of the Lancashire Asylums Board, it would appear that the new asylum at Winwick is approaching completion, as the board are about to appoint a medical superintendent at a salary of £600 a year, with furnished house and allowances. A committee has also been appointed to look for a site for another asylum. In fact, the board are doing their utmost to provide increased accommodation. The chairman intimated to a deputation from the Bolton board of guardians, who attended to ask the board to consider what could be done for that union in the matter of increased asylum accommodation, that they had an immense number of patients that ought never to have come to their asylums, owing to the action of the Local Government Board. The Asylums Board have also provided additional accommodation for 200 patients at Rainhill and for a similar number at Whittingham. It is a pleasing fact to find the services of the medical superintendents of the asylums appreciated, a resolution "that good service pay carrying no pension may be awarded to the medical superintendents of an asylum after 21 years' service" being carried by a large majority.

*Extension of the Hospital for Women, Shaw-street.*

Nearly £800 have been promised towards the cost of carrying out the alterations consequent upon the proposed extension of the Hospital for Women, Shaw-street. Five gentlemen head the list of subscriptions with £100 each.

*Medical Faculty, University College, Liverpool.*

The winter session of the medical faculty will begin on Oct. 1st. The distribution of medals, prizes, and certificates

for the previous session, and the opening address to the students by the Lord Bishop of Liverpool, will take place in the Arts Theatre of University College on Saturday, Oct. 13th, at 4 P.M. The medical faculty will hold their biennial dinner on the same evening at the Exchange Station Hotel.

*Donations to Liverpool Charities.*

The annual cyclists and harriers' parade, held in June last, has shown an increase of £200 over the amount collected in the previous year. The amount available for distribution among the hospitals was £720, the Stanley Hospital receiving £100, owing to special needs.

*Sanitary Inspectors' Association.*

A meeting of the members of the North-Western district centre of the National Union of Sanitary Inspectors was held at Ashton Hall on Sept. 1st. Mr. Francis Vacher, the president of the union, delivered the annual address which dealt entirely with the duties of sanitary inspectors.

Sept. 4th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

*Dublin Sanitary Association.*

AT the last meeting of the Council of the Dublin Sanitary Association which took place on August 23rd the following resolution was passed:—

That the council approve the proposition made by the Joint Committee of the Houses of Parliament on the Boundaries Bill that a joint drainage board for the city of Dublin and the townships of Rathmines and Pembroke should be constituted, and that in the opinion of the council a similar organisation for the administration of the Public Health Acts would be for the public advantage of the Dublin metropolitan area.

*Belfast Union Infirmary.*

At a meeting of the Belfast guardians held on August 21st Dr. James Lynass, visiting surgeon to the Union Infirmary, in a report on his department for the past half year, drew attention to the inconvenience of having to admit alcoholic cases to the general wards. There were, in addition to the 179 cases of ordinary alcoholism, 193 patients recently with surgical injuries associated with alcoholism. He advised that separate accommodation should be provided for these cases in the form of a male and female ward which would merely entail some structural changes in rooms existing on the ground floor of the infirmary. Again, it is absurd that cases of insanity should be treated in the infirmary. The proper place for such patients is the asylum, where they would receive expert treatment.

*Typhoid Fever Epidemic in Lisburn.*

At a special meeting of the Lisburn Urban District Council held on August 22nd it was decided in view of the increase of typhoid fever in the neighbourhood of Lisburn to adopt the Infectious Diseases (Notification) Act, 1899, and the Infectious Disease (Prevention) Act 1890. It was decided also that the sanitary sub-officer should act as professor of dairies.

*New Research Scholarship at Queen's College, Belfast.*

Her Majesty's Commissioners for the Exhibition of 1851 have again placed at the disposal of the authorities of Queen's College, Belfast, the nomination of a research scholarship of £150 tenable for two years. Previous holders of these exhibitions have been obliged to do their work in England. There is no reason why the present nomination might not be confined to original work done in some one of the excellent laboratories at Queen's College, Belfast.

*Precautions in Dublin against an Outbreak of Bubonic Plague.*

On account of the outbreak of bubonic plague in Glasgow the authorities at Dublin are taking every precaution to prevent the infection of the city through vessels arriving from suspected ports. Two vessels arrived on August 30th and were detained in the river until an examination was made by the medical officer of health of the South Dublin Union, who satisfied himself that there was no serious disease on board. The Irish Local Government Board have addressed a letter to the Dublin Corporation in which they state that no system of inspection of vessels, however perfect, was capable of preventing the introduction of cases which were not sufficiently developed to afford evidence for their detection. The Local Government Board, moreover, wish to be informed as to what action has been taken by the corporation upon the recent commission of inquiry into the public health of the city of Dublin and what steps have been taken to provide suitable accommodation for the isolation and treatment of cases of plague should they arise, and for the detection and isolation of suspicious cases, in order that the persons under observation might not be themselves subjected or expose others to the risk of infection. The Board also forwarded the report of one of its medical inspectors which contained the following:—

The sanitary condition of the city should earnestly engage the attention of the Public Health Committee and precautionary measures should in every detail be strictly carried out. The question of the destruction of rats (which have been notoriously found to be the medium of conveying infection) should also be considered by the sanitary authority. The destruction of these on incoming ships and in the warehouses by the river-side would be a preventive measure of undoubted advantage and is well worthy of consideration.

The corporation referred the matter to the Public Health Committee.

*Main Drainage of Dublin.*

The foundation stone of the new outfall works in connexion with the main drainage of Dublin was formally laid by the Lady Mayoress of the city on August 28th in the presence of a large and representative audience. The Lord Mayor said that the important contract for the outfall had been handed to Messrs. Pearson and Son whose representative, Sir William Pearson, he took that opportunity of welcoming to Dublin. The citizens might now look forward to the main drainage being completed within two years. Sir William Pearson alluded to the advantage that would result to the health and life of the citizens and remarked that the cost of the scheme would only amount to £1 for each inhabitant.

*Irish Poor-law Medical Officers.*

The disputes between the dispensary medical officers and the boards of guardians continue, and every week the papers are full of discussions at the meetings of the guardians. The following resolution has been passed by the Belfast, the Newry, and the Armagh boards of guardians:

That, as it is manifestly unjust that the guardians should be compelled to pay substitutes of medical officers while such medical officers are engaged in other work for which they receive ample remuneration, this board requests the Local Government Board to alter the dispensary rules (22, 23, and 24) to provide for such cases.

This resolution evidently refers to the fact that dispensary medical officers are often subpœnaed to the assizes as Crown witnesses, and though they are only paid two guineas per diem and expenses the guardians expect that they should pay their substitutes with the miserable pittance doled out by the Treasury. At the meeting of the Armagh board of guardians held on August 28th, Dr. S. Tate, Rich-hill, wrote that as he had been attending a bad case of erysipelas and had been then summoned to attend a midwifery case, which it would have been dangerous for him to attend, he had been obliged to call in Dr. G. Liddle, and he asked the board to order payment for such attendance. Some of the board thought, as the case of erysipelas was a private case and the midwifery case was a dispensary one, Dr. Tate should pay the fee himself. The board divided on the question, and it was decided by 10 votes to 9 to pay the fee.

*The Belfast Ambulance System.*

There is no public service of which the city of Belfast has greater right to be proud than its admirable ambulance system. From the report of the superintendent of the fire brigade (it is by this body the ambulance service is worked) for the year ending June 30th, I find that the duties in connexion with the ambulance service are increasing. 1875 calls were received, occupying over 991 hours, showing an average of 32 minutes per journey from the receipt of the call until the carriage returned to its station. The distance traversed was over 4599 miles, or an average of two and a half miles per single journey. In November last a new carriage was presented to the corporation. Admirable service was rendered by the ambulance system in connexion with the late Belfast Lough accident, the injured passengers being rapidly conveyed from the quay to the hospital.

*The Plague.*

The utmost precautions are being taken by the sanitary authorities in Belfast and the other Ulster ports closely related to Glasgow to prevent the introduction of the plague from that city into Ireland.

Sept. 4th.

# PARIS.

(FROM OUR OWN CORRESPONDENT.)

*The Parasite of Dourine.*[1]

AT a recent meeting of the Academy of Medicine M. Nocard, Director of the Veterinary School at Alfort, read an important paper upon Dourine and Its Parasite. The paper was prompted by a series of notes relative to the experimental study of dourine in the horse, which had been submitted to the Academy by M. Buffard and M. Schneider. M. Nocard stated in his paper that trypanosoma, first observed in 1896 by M. Rouget, an army surgeon, had been also found in 1899 by M. Buffard and M. Schneider in two animals suffering from naturally contracted dourine—namely, a horse and a donkey. After sundry passages through dogs the parasite re-transferred to horses communicated to them attacks of dourine absolutely like the naturally caught complaint and, like it, transmissible by coitus. Two well-known maladies are already known to depend upon the trypanosoma—namely, the "Surra" of India and the "Nagana" of South Africa. In future, then, dourine must be placed alongside of these two, even if all three are not simply different manifestations of the same parasite.

*True Essential Hæmaturia.*

It is the general opinion that there is no such thing as essential hæmaturia. M. Lancereaux, however, is not of this opinion and at the meeting of the Academy of Medicine held on August 2nd he spoke with the view of defending the thesis that there is a class of hæmaturia independent of any anatomical disturbance and which is simply due to some disturbance of the nervous mechanism which regulates the urinary apparatus. He cited the observations of Hoffmann who had reported cases of hæmaturia which gave rise to no dangerous symptoms, both in young and plethoric subjects, and in elderly men in whom it occurred, for example, after stoppage of hæmorrhage from piles. He also quoted from Latour d'Orleans who had reported two cases of hæmaturia occurring in young women of nervous temperament after a fit of rage or after suppression of the menses. Monneret had noticed the same thing in chlorotic and hysterical patients. M. Lancereaux had seen many cases of essential hæmaturia. Sometimes it occurred in an arthritic patient who also suffered from hæmorrhoids which had apparently shrunk and dried up (this happened in two cases). Another case was that of a woman who had suffered from hæmaturia for a year. Nothing seemed to stop it until she took one gramme of sulphate of quinine daily for eight days. Another case was that of a man who had hæmaturia every 15 days for six months. He was going to have his kidney removed when M. Lancereaux prescribed a dose of sulphate of quinine varying from 1·25 grammes to 1·57 grammes to be taken every evening. After six days the hæmaturia had entirely disappeared. As a rule the general health is not affected in this form of hæmaturia. The patient has a feeling of uneasiness over the kidneys but no real pain, the hæmorrhage is intermittent, and between the crisis the urine is absolutely normal. The blood and urine are intimately mixed in the bladder. Finally, sulphate of quinine in doses of from 0·80 to 1·50 grammes cures almost all these patients. Such are the characters, diagnostic points, and treatment of this remarkable complaint.

*Gastric Disturbances at the Menopause.*

M. Dalché recently discussed this question before the Therapeutical Society. According to him gastric disturbances are frequent among women at the time of the menopause. Two etiological factors are present: (1) ovarian insufficiency, and (2) the congestive attacks (*poussées fluxionnaires*) which affect the different organs at this time. The immoderate use of tea, coffee, tobacco, strong drinks, and alcohol gives rise to serious gastric trouble. Also a great number of gastric troubles may be set down to a condition of neurasthenia to which most women have to pay tribute more or less heavy at the time of cessation of menstruation. If any doubt is raised as to the connexion between the menopause and gastric trouble proofs are at hand by recalling to mind the sequelæ of a surgically-induced menopause. In women who have had both ovaries excised the medical man sees among an infinite variety of symptoms disinclination for food, gastralgia, hæmatemesis, together with diarrhœal and hæmorrhoidal crises which did not exist while the patient menstruated. Treatment must vary according to circumstances, but the connexion of the menstrual function with these complaints offers some indications. If, for instance, the patient has hæmorrhage from piles it should be encouraged rather than stopped. Mustard foot baths, hot sitz baths, and dry cupping over the kidneys all give relief. If these are not sufficient recourse must be had to blood letting. A fairly large number of leeches may be placed on the inner sides of the knees, as recommended by Trousseau, or applied to the thighs, the hypogastrium, or the epigastrium. In cases where the pain was very acute M. Dalché obtained good results by the use of blisters. Between the crises hydrotherapy is most useful and the effects of ovarian extract must not be lost sight of.

Sept. 4th.

[1] Dourine, or Maladie du Cöit, is an infectious disease occurring in cattle and horses transmitted by sexual intercourse.

# BERLIN.

(FROM OUR OWN CORRESPONDENT.)

*Alleged Existence of Plague in Cardiff.*

No case of plague has occurred in Hamburg since the one mentioned in my last letter.[1] The energetic measures of the sanitary authorities of Hamburg which were carried out under the control of Dr. Nocht, the able chief medical officer to the port, have proved successful. In order to avoid infection no necropsy was made after the death of the unfortunate steward. The vessel was thoroughly disinfected and has now left the quarantine station where it had been for about a fortnight. The authorities of the port of Hamburg did not understand at first where the man could have caught the disease. The steamer *Rosario* had come direct from Cardiff where it had lain for a rather long time. The sanitary officers, therefore, concluded that the port of Cardiff must be infected with plague, probably by steamers coming from Oporto and Bombay. One of the leading Berlin daily papers which has relations with the Government stated 10 days ago that the Imperial Health Office was convinced that plague existed at Cardiff and that there was reason to believe that in other British ports cases of this disease had occurred without being recognised. This was written about a week before the announcement that the disease had appeared in Glasgow.

*Precautions against Plague.*

With a view to avoid infection of German ports by vessels arriving from abroad the Minister of Public Instruction, as chief of the Prussian medical department, convoked a meeting of the medical members of the above department and some other hygienists, including Professor Pfeiffer who had visited India for the study of plague. The meeting discussed the measures taken by the local authorities which were generally found to be satisfactory. The Minister appointed two additional sanitary officers for the port of Stettin where the medical inspection of vessels arriving from abroad was inadequate.

*A False Alarm of Plague in Berlin.*

A fortnight ago the public were again alarmed by the announcement that a case of plague had occurred in Berlin. This had no connexion with the case in Hamburg, the suspected patient being a servant of the Royal Institution for Infectious Diseases, a man who had to clean the rooms in the laboratory where specimens of plague cultures procured from Oporto were preserved. The regulations of the institution are very strict. No one is allowed to enter the rooms where dangerous cultures of any kind are kept except the medical men who work there and one servant who assists them and has to clean the rooms. The members of the staff working in these rooms have to wear a special dress capable of being disinfected and the rooms themselves are situated in an out-of-the-way wing of the building. Everything is thus done to avoid an event like that at Vienna, where the carelessness of a drunken servant three years ago led to an outbreak of plague in the hospital, fortunately confined to three or four cases. Notwithstanding these precautions one of the medical staff working in the plague laboratory a few days ago observed a carbunculous swelling on the nose of the servant attached to the laboratory. The swelling was of a suspicious character and owing to the possibility of an infection to which

[1] THE LANCET, August 18th, 1900, pp. 494 and 560.

the man might have been liable by his work he was at once strictly isolated in one of the pavilions of the hospital of the institution. This proved to be the more necessary as on microscopical examination suspicious bacilli were found in the pus of the part. The patient was attended by the medical man under whom he had been employed in the laboratory and who was isolated along with him in the pavilion. Moreover, the family of the servant and some friends with whom he had last spent an evening, although in perfect health, were all isolated in another ward. Nobody was allowed to enter the ward, the food being supplied to the inmates through the windows. Fortunately the alarm proved to be a false one, as the patient got well in a few days, and cultures of the suspected bacilli were found to be harmless when inoculated into rats and mice. The man and his family were therefore allowed to leave the hospital where they had spent some rather anxious days.

*Treatment of Constipation.*

Dr. Ziemssen of Wiesbaden, writing in the *Berliner Klinische Wochenschrift*, recommends resort to the stomach-pump and to washing out the stomach in cases of persistent constipation. By the daily application of this method the peristaltic movements not only of the stomach but also of the entire gastro-intestinal canal become increased so that soft fæces are generally passed after about half an hour. The success is often so obvious that patients who have suffered from constipation for a long time are able after a week to have a spontaneous action of the bowels every morning and continue to do so for years. The results are often superior to those obtained by aperients, massage, and electricity. Dr. Ziemssen recommends that from half a litre to a litre of Wiesbaden Hochbrunn water should be used and that the stomach should be evacuated at once by lowering the funnel of the pump. This procedure is to be repeated from 15 to 20 times every morning with a greater quantity of water every time till the patient becomes aware of a slight pressure within the stomach. Dr. Ziemssen is of opinion that the treatment acts like massage of the abdominal muscles and that the contractions are propagated to the intestines. The drinking of Wiesbaden Hochbrunnen water has only a temporary effect as an aperient, whilst the application of common hot water by the stomach-pump is useless. Apart from chronic constipation the method has proved useful in chronic catarrh of the stomach, dyspepsia, atony, dilatation, hyperacidity, neuroses, and chronic ulcers of the stomach.

*Medical Graduation of Women.*

By a recent decision of the German Federal Council female medical students of German nationality are entitled to be admitted to the State examination in medicine even if they have passed their preliminary examinations and received their medical education in Switzerland. As the State examinations in medicine begin in November the medical men in Germany will very soon have the opportunity of meeting female practitioners, the number of German female medical students in Switzerland being rather considerable. Those ladies, also, who have already settled in Germany with Swiss diplomas will now be in a position to take German qualifications by passing the State examination without being forced to begin their curriculum again. The present favourable disposition of the Government towards medical women has led to the rather absurd situation that female medical students enjoy privileges as to study abroad which are refused to the male sex.

## ROME.

(FROM OUR OWN CORRESPONDENT.)

*Sanatoria for Tuberculosis in Italy.*

AT a moment when all hearts are softened by the tragical death of King Humbert, whose kindness to the poor and sympathy with their sufferings are fresh in the minds of the people, Professor Baccelli's suggestion for commemorating his memory by the establishment of sanatoria for the treatment of tuberculosis throughout the country will, it is hoped, be received with substantial support. The leading Roman daily *La Tribuna* makes an eloquent appeal in behalf of the scheme, which it seems has already been initiated by the formation of an influential committee who are to begin forthwith the organising of a great "Sanatorio Umberto I. per la Tuberculosi" as Italy's national monument to the memory of her murdered king. Certainly no record in bronze or marble could so fitly commemorate the best qualities of the late monarch than an institution which would have for its aim the prevention of the untold misery and fearful loss of life directly or indirectly attributable to that most insidious and widespread of all diseases, tuberculosis; and nothing could better serve to perpetuate the memory of his ready sympathy with the sufferings of his people shown on all occasions, but most conspicuously perhaps during times of dangerous epidemics, when he was wont to throw himself heart and soul, regardless of personal risk, into the work of visiting and helping the sick and comforting the dying. The scheme thus begun is an ambitious one, comprehending the founding and establishment of sanatoria throughout the whole of Italy under one control and direction, with a central seat in Rome and branches at such other principal points as are best suited by their climatic and hygienic conditions for the cure of tuberculosis. Owing to its geographical position Italy is singularly adapted for carrying out such a great scheme successfully, including as it does in small compass a vast number of localities totally distinct from one another in their climatic peculiarities and yet possessing in common the great advantages of pure air and the perennial sunshine with which the whole peninsula is blessed. With these different sanatoria all under one management and each offering its own special advantages of climate derived from its topographical position it would be possible to place each patient, no matter where he presented himself, in the surroundings best suited for his particular case as indicated by the nature of the disease, the stage of the destructive process, and the various complications which so greatly determine the kind of climate required. A considerable sum of money has already been collected in Rome for setting the scheme on foot and at Milan enough has already been forthcoming to start a Lombard institution. In Naples the munificence of the Duchess Ravaschieri has made the foundation of the proposed sanatorium at Pozzuoli no longer uncertain, whilst in Palermo another public benefactress, Signora Giovanna Florio, has offered a donation which will bring the fund for the erection of a Sicilian sanatorium to a total of about £10,000. Unfortunately the Villa Hygeia at Palermo about which so much was heard last winter has fallen into the hands of speculators, and in place of the sumptuous hospital for which it was originally intended it is now to be converted into the "Grand Hotel."

*Sanitary Progress in Italian Cities.*

Whilst it may be doubted whether the scheme for the multiple establishment in Italy of sanatoria for the treatment of tuberculosis is not too ambitious ever to be realised and will not prove to be more creditable to the heart than to the head of its sanguine originator, it must be confessed that the Italians are endowed with a degree of public spirit, especially in the direction of sanitary reform, which makes even so great an undertaking assume tangible shape. Our preconceived notions of the Italian character might lead us to regard them as unpractical and chimerical people, but their sanitary progress contradicts this view. Of this we have striking evidence in Rome itself, where, in the face of apparently overwhelming financial and other difficulties, vast schemes of improvement have been undertaken and carried out which have had the effect of a veritable transformation. It is true that to the artist and the archæologist this transformation has not always been a welcome one, but love of the antique and the picturesque must give way when the health and well-being of a large population are at stake. The wholesale removal, for example, of ancient and interesting but insanitary houses and streets; the erection of modern buildings upon such classic ground as the gardens of Sallust or Mecænas; the disappearance of those picturesque banks which made the Tiber so favourite a subject for the painter's brush and the substitution for them of hard, monotonous lines of masonry; all this is vandalism and desecration in the eyes of the lover of Old Rome, who at the same time is fain to admit the vast improvement affected thereby in the cleanliness, comfort, and salubrity of the city. The mortality returns bear eloquent testimony to this amelioration and compare very favourably with those of the other large cities of Europe and of America, among which Rome now stands in the first rank for lowness of its death-rate (17·2 per mille in 1899). In the course of the last decade the extensive buildings on the Esquiline hill, in the Ludovisi quarter, and

on the Prati di Castello, outside the Porta Pia, each in itself a small town, have been added to the ancient city, and in the latter district new streets such as the Corso Vittoria Emanuele and the Via Cavour, leading from it to the new districts, have been opened up. The Tiber, too, which formerly did great damage to adjoining property by its frequent floods, has been effectually walled in by immense embankments of masonry over 40 feet in height from their base, extending on the right bank for a distance of more than four and a half miles, and on the left of six and a half miles. Closely connected with this gigantic undertaking was the construction of the huge main sewers, one on each bank, for collecting the sewage from the branch sewers and carrying it down into the river to a point far below any probable extension of the city seawards. These have a length of about six and a half miles and 11 miles respectively. The total cost of these improvements along the Tiber has reached a figure close upon £4,000,000 sterling. Similar though less stupendous enterprises have been undertaken or are now actively in progress in most of the other large cities of Italy, notably in Genoa, Milan, Naples, and Palermo; and indeed it may truly be said that such an enlightened spirit of progress has entered into the municipal bodies generally as to ensure at no distant date the attainment of a very high standard in the sanitary condition of all the more important cities and towns of the kingdom, particularly those most frequented by foreign visitors.

Sept. 3rd.

## CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

*Plague in Constantinople.*

BESIDES the case of bubonic plague which occurred recently on the ss. *Niger* of the Messagéries Maritimes a second case is reported on board the same steamer. The first was a boy, aged 14 years, who came from Kharput and embarked at Alexandretta; the second case was that of a steward of the same ship. Their illness began with chill, slight fever in which the temperature rose to 40° C., and with enlargement of the glands of the groin as well as of the armpit. This outbreak has made a certain impression on some of the visitors, who left Constantinople immediately. They did so not so much because they were afraid of the plague as to avoid the quarantines which the neighbouring governments would subject them to. I am glad to state that the public health here is perfect, but in spite of the good health of the place Russia has imposed a quarantine of 10 days on all ships arriving from Constantinople. They undergo the quarantine at Theodosia.

*The Twenty-fifth Anniversary of the Sultan's Reign.*

To-day is the twenty-fifth anniversary of the reign of H.M. the Sultan Abdul Hamid II. The Sultan holds in very high esteem the medical profession and never allows an opportunity to go by without compensating merit by honours. Among the other presents to the Sovereign there is that of the Imperial Medical Society, known by repute to many of your readers. The Imperial Medical Society, which was founded during the Crimean war under the auspices of Sultan Medjid by the chief physicians of the allied armies, are presenting to His Majesty an address of congratulation and of good wishes on the occasion, and it has been decided to publish a work relating all that has been done under His Majesty's reign in connexion with hygiene and medicine. The Sultan Abdul Hamid II. was the first among the sovereigns to honour the late Professor Pasteur with the decoration of the Grand Order of the Medjidieh. Dr. Zoeros Pasha, an army physician with the rank of general, conveyed with the compliments of His Majesty the highest rank of the Order of the Medjidieh to Pasteur with £500 as a contribution to the building of the Institut Pasteur in Paris. Professor Pasteur was asked to teach the new science of microbiology to Dr. Zoeros Pasha. In fact, he was taught how to prepare the antirabic virus and how to treat those who were bitten by rabid dogs, and in May, 1887, the first antirabic institute outside France was installed at Constantinople. More than 2500 persons have been treated in this antirabic institute by Dr. Zoeros Pasha, among whom there have been some deaths, averaging 0·5 per cent., and this because most of the patients were too late in taking advantage of the antirabic treatment. In one case an officer of the army who had been bitten by a rabid dog at Ismid (Nicomedia) went to the military hospital of Haidar Pasha where only the wounds were dressed, and shortly after he left the hospital he had symptoms of rabies. Then, and not until then, his case was brought before Dr. Zoeros Pasha. Needless to say that he died. This fact was reported to the Sultan, but not in the right way, and as a consequence Dr. Zoeros Pasha, in spite of his rank and of his long and faithful services, was replaced by Dr. Mari, a Frenchman. The Sultan has also presented the empire with an institute where anti-diphtheritic serum is prepared and the medical men of the country hope to have soon an institute for the preparation of the anti-plague serum. The solicitude of the Sultan for the health of the Turkish army is noticeable. During the last epidemic of cholera he ordered that "water of best quality" from the renowned spring of Karakoulak should be served to the soldiers, and as no cases of cholera were registered among the Turkish soldiers the spring must be considered to deserve its fame.

Constantinople, Sept. 1st.

## CANADA.

(FROM OUR OWN CORRESPONDENT.)

*Annual Report of the Toronto Health Department.*

THE annual report of the medical health officer of the city of Toronto, Dr. Charles Sheard has just been issued and contains the operations of the department for the past year, as well as several exhaustive and important papers dealing with the treatment and prevention of diphtheria and small-pox, with food inspection, and with plumbing and draining. In the sanitary department there were 3213 complaints, 7881 inspections of nuisances, 6234 house-to-house inspections, besides inspections of livery stables, slaughter-houses, &c., and 79 cases were prosecuted in the police-court. The food inspector reported only eight instances of cattle in the market entirely unfit for food. During the year this officer made 9910 shop inspections and made considerable confiscations. The inspection of milk, a vital and important question, has apparently been handled ably by the health department of Toronto during the past year. The total milk-supply of the city embraces 1634 cans daily, which is furnished from an area of country of upwards of 30 square miles. In the opinion of Dr. Sheard, wilful adulteration of this article of diet is not practised to any extent in his jurisdiction. Education of the public will be, however, continued along the lines of perfecting the milk-supply. During the year there were 2397 inspections of city milk depôts, 419 inspections of cow byres, and 598 samples of milk were collected and analysed. As regards contagious diseases there were reported during the year 225 cases of typhoid fever, 1013 of scarlet fever, and 458 of diphtheria, of which 34, 55, and 82 cases respectively resulted fatally. The total number of patients of all kinds admitted to the civic hospital during the year was 804. Of these, 458 had scarlet fever, 334 diphtheria, eight small-pox, one chicken-pox, and three measles. The number of deaths during the year was 58, but six of the patients who died were moribund when brought into the hospital, expiring almost immediately. The death rate, including those who were moribund, was 6·16 per cent., and excluding them it was 5·48 per cent. Professor Shuttleworth, the civic bacteriologist, in his report on the bacteriological work, goes very fully into the nature and duration of diphtheria, paying particular attention to susceptibility as influenced by age. Of 238 cases of true diphtheria the ages were as follows: five years and under, 32·6 per cent.; from five to 10 years, 29·6 per cent.; from 10 to 15 years, 12·7 per cent.; over 15 years, 25·0 per cent. Thus according to this statement children under five years of age are more susceptible. The deaths were as follows: under five years, 24; from five to 10 years, five; from 10 to 15 years, three; and over 15 years, four. During the last year small-pox has invaded the city five times. The medical officer of health gives it as his opinion "that the two secrets of success in handling the disease in a densely populated community are, first, the capability of accurately diagnosing the disease; secondly, the prompt, complete, and absolute isolation of those

infected and exposed to infection." Opposition to vaccination, he goes on to state, so far as the city of Toronto is concerned, is non-existent.

*Typhoid Fever at the Royal Victoria Hospital, Montreal.*

There were treated in the wards of the Royal Victoria Hospital, Montreal, during 1899, 98 cases of typhoid fever, of whom 65 were males and 33 were females. Of these 98 cases 86 were treated to a conclusion, and the observations of the senior resident physician there, Dr. B. D. Gillies, are interesting. As regards age the average age of all the patients was 23 years, the youngest being only three and a half years and the oldest 58 years. Classified in decades, four cases occurred under 10 years of age; 21 between 10 and 20 years; 40 between 20 and 30 years; 16 between 30 and 40 years; four between 40 and 50 years; and in one case over 50 years. The largest number of cases was admitted during the month of August; the smallest number were admitted during December. 52·3 per cent. began in July, August, and September; 18·4 per cent. during October, November, and December; 18·6 per cent. during April, May, and June; and 11·7 per cent. during January, February, and March. Concerning the duration of the cases the average number of days in hospital was 39·5; the average duration of fever was 24·6 days; the longest period of fever was 58 days; the shortest period of fever was eight days. In one case there was definite proof that infection had been contracted through milk. Five cases were admitted from one family where defective sewerage was known to exist, whilst in four other instances two or more members of the family were ill at the same time. Referring to the observations regarding the symptoms it is noticed that 95·4 per cent. of the cases developed gradually with general malaise, frontal headache, and anorexia as the most prominent and constant symptoms. In two cases pain in the abdomen was severe, of sudden onset, and localised so as to simulate an attack of appendicitis. Diarrhœa was present at the onset in 20·9 per cent.; epistaxis in 18·6 per cent.; vomiting in 34 per cent., and delirium in 18·6 per cent., and in nearly every case it was of a low, muttering character. There was an eruption present in 72 per cent. of the cases, the earliest appearance of the rash being on the fourth day of the disease and the latest on the fortieth day of the disease, whilst in one case the rash appeared during the relapse alone. The shortest duration of the rash was three days, the longest was 27 days, the average being 11 days. The spleen was palpable in 67·4 per cent. of the cases; in one case on the first day of the disease; in another until the fourth day of the relapse, being the twenty-fifth day of the disease; on the average it remained palpable for 12 days. A definite relapse occurred in 12·7 per cent. of cases, the longest duration of any single relapse being 29 days, the shortest eight days, and the average 18 days, whilst in three cases the relapse was stated to be more severe than the original attack. Temperature had been normal for 17 days in one case when the relapse set in, while in another it had only been normal for 24 hours when the relapse set in. One patient was admitted to the hospital for typhoid fever who had recovered from an attack four weeks previously. As regards temperature, the highest was 106·4° F.; the maximum in one case was 100·4°; the average in all the cases was 103·4°; and in 48·8 per cent. of the cases it reached 104° or over. The Widal test was employed in all the cases. In only four cases was the reaction negative during the whole course of the disease, and of these three were regarded as abortive cases; in the most prolonged of these cases the temperature remained elevated for 10 days and there were no rose-spots present in any of the four. In one case the reaction appeared as early as the fourth day of the disease; in another case it was not positive until the eighteenth day of the disease; on the average it was present on the eighth day. In six of the cases at the date of discharge from the hospital the reaction has been tried and resulted positively in all. Investigations are being pursued further along this line. The typhoid fever mortality has been higher this year than any other since the hospital opened, there being seven deaths, or 8·16 per cent. Hæmorrhage was the cause of death in three cases, hæmorrhage and perforation in one, perforation in one, and profound intoxication in two cases. During the six years of its existence 494 cases of typhoid fever have been treated in this hospital, divided as follows with deaths:—1894, 84 cases, three deaths; 1895, 84 cases, four deaths; 1896, 72 cases, no deaths; 1897, 75 cases, seven deaths; 1898, 93 cases, four deaths; 1899, 86 cases, seven deaths.

*State of Health in the Yukon.*

The report of the medical health officer, Dr. J. W. Good, dated Dawson, June 23rd, gives the state of health of that district at that time. There was then no typhoid fever, no diphtheria, no small-pox, and no dysentery. More recent reports state that there are now five cases of small-pox down the river from Dawson City which are quarantined, and that Dr. Montizambert, Director-General of Public Health at Ottawa, is on his way there to investigate the outbreak. At the same date last year cases of dysentery and of typhoid fever were plentiful. The number of paying patients in the Good Samaritan Hospital at Dawson was 11; non-paying, 12; total, 23. The number of paying patients in St. Mary's Hospital was 4; non-paying, 14; total, 18. Non-paying patients must make a declaration as to the state of their finances, which is also certified to by a friend, and the rule works smoothly. Months ago the medical officer of health, noticing that small-pox was prevalent in other portions of Canada, advised the Board of Health to lay in a supply of vaccine, as vaccination was not being performed to the extent it should be in that country. The water-supply of the city is stated to be good and in the hands of a good company and the use of drinking water from other and questionable sources is entirely displaced. Great improvements have been made in the way of drainage and removing of obstructions of various kinds from the streets, and good work has also been done in the way of prosecuting merchants and others who profit by the sale of diseased and spoiled articles of food.

*The Medical Department of McGill University.*

The annual convocation for conferring medical degrees was held on June 23rd, when 75 graduates, having fulfilled all the requirements to entitle them to the degree of M.D., C.M. from the University, were presented therewith. A new departure this year, the first of its kind in either Canada or the United States, was the awarding of diplomas of Public Health to four graduates in medicine who had taken this special course at McGill University. These gentlemen were W. W. Ford, B.A., M.D.; J. E. Laberge, M.D.; H. S. Shaw, M.D.; and J. E. Williams, M.D. This convocation brought to a close the sixty-eighth working session of the medical faculty of McGill University. The faculty originated in 1829, the first session beginning with 30 students, and its yearly sessions have continued without interruption, with the exception of the three years of the Canadian Rebellion from 1836 to 1839, the session of 1839–40 opening with 28 students. In making his address the Dean, Dr. Craik, stated that it had been his good fortune to be connected with 50 sessions. 50 years ago the total number of students of all kinds in the faculty was 53; this year 478 were enrolled on the Register, 31 more than last year, and of these 457 were proceeding to their degrees while 21 were doing post-graduate work. 52 of these students came from the United States, 14 more than the previous year, which goes to show the estimation in which this first of Canadian medical schools is held by our neighbours to the south of us. The new department of Public Health has been fashioned, with modifications, after similar qualifications given by some of the institutions of Great Britain.

Toronto, August 18th.

## NEW YORK.

**(FROM OUR OWN CORRESPONDENT.)**

*A New Movement for the Organisation of Private Asylums.*

THE Association for the Study and Cure of Inebriates have held a meeting for the purpose of securing a thorough organisation of all private asylums which exist for the treatment of mental diseases and drug cases. It was stated that there are nearly 100 asylums, homes, and sanatoriums in the New England and Middle States for the treatment of inebriates, mental, and nervous cases, over half of them being charlatan institutions. Such institutions are without organisation or system, are without State or local licence or supervision, and are managed by unknown persons. A large number of representatives of different asylums were present at this meeting and the following propositions were agreed upon as representing the objects of the conference: 1. To promote the scientific study of alcohol and other drug neuroses and to encourage desirable and special legislation

with reference to the care and control of such cases. 2. To isolate the chronic pauper inebriate from the insane and criminal class and to secure the erection and maintenance by the several States of institutions for the segregation and special treatment of chronic pauper inebriates and to incorporate farm colonies or other forms of institutional relief which shall combine medical care with occupation, control, and discipline. 3. To secure in all States the special supervision and inspection of all institutions for the care and control of inebriates and other drug neuroses. 4. To discourage and prevent all efforts to treat alcoholic inebriety or the opium or other drug addictions with secret drugs and other so-called specifics, and to prohibit the sale of all other nostrums which claim to be absolute cures and which contain alcohol, opium, or its alkaloids, or other harmful or pernicious drugs, or which contain substances which are inert and are fraudulent impositions on the public. 5. To encourage, as an association, every individual or organised effort to study scientifically and practically all the various means and methods of both cure and prevention which are found valuable in the treatment of alcohol and other drug addictions. 6. There are many institutions in this country which treat the alcoholic and other forms of drug addiction associated with mental and nervous cases. These institutions should all be organised and follow some general principles and methods of work. By this means public opinion could be more effectually influenced and legislation secured resulting in a great advance in the uniform scientific treatment of such cases.

*Jewish Charities and the Treatment of Tuberculosis.*

The Jewish charities of the United States rank, as a class, among the best in every community. They are well managed and well supported and their aims are definite and are sought to be obtained by the most effective agencies. The first annual meeting of the National Conference of Jewish Charities was held in Chicago this summer when delegates from 35 cities were present. A paper on Federation *versus* Consolidation of Jewish Charities in a City was read by Professor Morris Loeb of New York city. Instead of obtaining funds for charitable societies by means of fairs, entertainments, &c., he recommended more concerted action in bringing to the notice of the community the charitable institutions in its midst and suggested as an alternative for the present system a scheme of federation, wherein the various societies would retain their individuality but would receive their appropriations from a common treasury. Another paper, discussing the relation of bad housing to poverty, showed that the main causes of poverty in the tenement house districts of New York, as proved by statistics gathered for the years 1898 and 1899, were as follows: lack of employment, 19 per cent.; sickness, 15 per cent.; insufficient employment, 11 per cent.; intemperance, 8 per cent.; and no male support, 5 per cent. In a paper on Tuberculosis as Affecting Jewish Charities Dr. Lee K. Frankel, of New York, called attention to the fact that consumption was on the increase among the poorer classes of Jews, statistics collected from the various cities throughout the country proving this fact. He also affirmed that the medical profession of to-day was nearly unanimous in the opinion that special climatic conditions are no longer necessary for the cure of tuberculosis and for this reason he suggested that each constituent society in the conference should endeavour to secure the establishment of sanatoria for the treatment of this disease near its own community. The work of the conference may be summarised as follows: (1) the adoption of uniform rules and regulations regarding the transportation of applicants from one city to another; (2) the care of the consumptive poor; (3) the establishment of a systematic telegraphic code between cities to be used by the various constituents of the conference; and (4) the recommendation of a uniform system of records to be used by the small communities as well as by the larger cities and the publication of annual reports after some uniform plan.

*The Prevention of Premature Burial.*

The horror of being buried alive has resulted in the formation of a society in the city of New York known as the "American Society for the Prevention of Premature Burial." The society has formally applied for a charter and expects soon to demonstrate the usefulness of such a body. Medical men, the promoters state, issue certificates of death without subjecting the body to a thorough physical test in order to ascertain absolutely the absence of life. The proposed charter of the society provides that physicians certifying to the death of persons in the State of New York shall sign a certificate prepared by the society stipulating that the following tests, or as many of them as may be decided upon, have been applied to the body of the supposed dead without having produced any indication of life: two or more incisions in an artery; the palm of the hand exposed to the flame of a candle; a mirror or crystal held to the lips and no sign of respiration; a hot iron or steel placed against the flesh without producing blisters. The society also recommends the establishment of chapels for the repose of bodies during a certain number of hours.

*Railway Accidents.*

The latest official figures given by the Interstate Commerce Commission show that during one year there were in the United States of America, all told, 51,743 casualties resulting from railway accidents. Of this number 7123 persons were killed and 44,620 were injured. The number of trespassers killed and injured was very large, there being 4040 killed and 4730 injured. The number of passengers killed was 259, and the number wounded was 3442. During the previous year there were 221 killed and 2945 wounded. The ratio of those killed to those who travelled was one person to every 2,189,023. Of the employés one out of every 420 was killed and one out of every 27 was injured. Of those working on locomotives one was killed to every 165 persons. In New York State where safety brakes have been employed there were 260 persons killed, as against 279 for 1898, and 6725 injured against 6988 for the previous year.

*Trustees for Children of the City of Boston.*

This is the third year during which not only the "pauper" and "neglected" children, but the institutions for truant and juvenile offenders have been under the charge of an unpaid board of men and women. This class number nearly 1500. The administration has been marked by several distinct steps in advance. One was the complete abandonment of institutional life for normal children, other than those under sentence, and another very important step was the thorough investigation of every case before admission. This was undertaken not merely to determine the question of legal eligibility, but to ascertain whether admission to the status of a city dependent is the best thing practicable for the child. The mother is carefully consulted, charitable societies are appealed to, and every effort is made to find the wisest solution.

*Instruction for the Deaf.*

Mr. J. C. Gordon of the Illinois School for the Deaf gives the following figures which will be found interesting: The number of pupils in schools for the deaf in the United States in 1899 is 10,291. Of these 61 per cent. are taught speech, oral instruction being used exclusively, or a "combined" method. The balance of 39 per cent. are not taught speech, but use the sign or manual methods exclusively. It is noticeable that the oral method predominates most strongly in the New England or Middle States. In the Central and Western States 58 per cent. are taught speech, while in the Southern States only 31 per cent. are under oral instruction.

August 18th.

# Obituary.

JOHN TRESSILIAN TOLL, M.R.C.S. ENG., L.R.C.P. EDIN.

THE news has just reached this country of the death of Surgeon-Major Toll on the voyage from the Cape to Melbourne on board the ss. *Australasian*. Mr. Toll was born in London about 48 years ago and was taken by his parents to South Australia when a child. He was educated at the Adelaide Grammar School, but came to this country in 1871 and entered Queen's College, Birmingham, and all his fellow-students will hear of his untimely death with the deepest sorrow, for "Jack" Toll enjoyed a well-deserved popularity with all. He held two resident appointments at the Birmingham General Hospital, and he also studied in Edinburgh, at University College Hospital, and in Paris. Soon after obtaining his diploma in 1877 he returned to Australia as surgeon in charge of the emigrant ship *Airlie*. Shortly after his arrival he entered

into partnership with his brother-in-law, Dr. Gething, and on the death of that gentleman in 1883 he became Government health officer. He also had the post of medical officer to the Port Adelaide corporation for 15 years. He had the medical oversight of the Largs Bay and Glanville forts and also of the colonial warship *Protector*. When arrangements were being made for the despatch of the first South Australian contingent to the front he offered to accompany the force as a volunteer medical officer without remuneration and went with the troops up the country to Bloemfontein where he was attached to one of the hospitals. Here he was stricken down with the terrible scourge enteric fever. He, however, became convalescent and was invalided home. The *Adelaide Advertiser* of June 25th, commenting on the voyage, says: "The voyage was closed by one sad incident of especial interest to South Australia. Surgeon-Major Toll of Adelaide, who had himself fallen a victim to enteric fever, was returning home. He quickly became a great favourite on board. He was of that temperament which makes men popular. On June 20th the gallant surgeon-major expired. He was seized with an epileptic fit and sank soon afterwards. He was buried at sea with full military honours but his death clouded the end of the voyage."

He married a daughter of the late Mr. W. R. Mortlock and a niece of the Hon. A. Tennant and leaves an only son.

### JOHN ORTON, M.D. T.C.D., L.R.C.S. IREL.

DR. JOHN ORTON died on August 19th at Beeston, Notts, where he was born 55 years ago, the son of John Orton, L.S.A. (an apprentice of John Abernethy), who practised at Kegworth, where in 1826 he was the first English surgeon to successfully perform primary amputation at the hip-joint. Dr. Orton succeeded to his father's practice at Beeston about the year 1867, so that for some 70 years the name has been a well known one in Beeston and the neighbouring villages. The subject of this notice was a man of strong character, a passionate lover of Nature, simple and unassuming, but strong in his hatred of anything like pretence or sham, unconventional and ever good-natured and kind. He was a vigorous athlete, a votary of cricket, archery, and lawn-tennis. Beeston by his death loses an "institution" and the profession an upright capable general practitioner. To his many friends and relations the memory of Dr. John Orton will be a sweet one. The unflinching way in which he met his long and painful illness was part and parcel of his character. Dr. Orton never married.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Wilhelm Wagner of Königshütte, a surgeon of great ability, who, though he was unconnected with the teaching staff of any university, yet had been granted the title of professor.—Dr. Porson of Nantes, who distinguished himself during the Franco-German war and who subsequently helped to establish the Union of French Medical Syndicates, being president of the union for five years.

## Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Baltimore Medical College:* Dr. Rowland has been appointed to the Chair of Midwifery.—*Berlin:* Dr. Max Nitze has been promoted to an Extraordinary Professorship of Diseases of the Urinary Organs.—*Chicago (Rush Medical College):* Dr. Westcott has been appointed Assistant Professor of Ophthalmology.—*Freiburg:* Dr. Wilhelm Autenrieth has been promoted to an Extraordinary Professorship of Chemistry.—*Lausanne:* Dr. Freyer has been recognised as *privat-docent* of Internal Pathology.—*Prague (German University):* Dr. F. Weleminsky has been recognised as *privat-docent* of Hygiene.—*Rennes:* Dr. Bodin has been appointed Professor of Pathological Anatomy and Bacteriology.—*Yale:* Dr. Bartlett has been appointed Professor of Pathological Anatomy.

MR. H. E. BURCH, M.R.C.S. Eng., L.R.C.P. Lond., has resigned the appointment of Resident Surgeon to the Memorial Hospital, Bulawayo.

THE RECENT SOLAR ECLIPSE.—The report of the expeditions organised by the British Astronomical Association to observe the total solar eclipse of May 28th, 1900, will be contained in a volume shortly to be issued from the office of *Knowledge*. The work will be edited by Mr. E. Walter Maunder, F.R.A.S., and will contain many fine photographs of various stages of the eclipse.

NORTH DEVON INFIRMARY.—The annual meeting of the subscribers and friends of the North Devon Infirmary was held at Barnstaple on August 21st under the presidency of Lord Fortescue. The report stated that during the past 12 months 654 in-patients and 2269 out-patients had been treated. The average daily number of in-patients was 46, the average stay of each being 25½ days. The financial statement showed that the total ordinary expenditure exceeded the ordinary income by about £500. The committee reported that the convalescent home in connexion with the infirmary at Morthoe was doing a most useful work.

FEES FOR MEDICAL WITNESSES.—An inquest was held at Trowbridge, Wiltshire, on August 27th, upon a boy, aged 10 years, who had died from tetanus at the cottage hospital. The jury returned a verdict in accordance with the medical evidence and the county coroner (Mr. Sylvester) expressed regret that he was unable under the county council regulations to allow a fee to the medical attendant as the death occurred in a hospital. He added that he was of opinion that the Wiltshire county council misunderstood the terms of the Act, which applied only to paid medical officers of hospitals and not to honorary surgeons as in the present case.

LITERARY INTELLIGENCE.—The Sanitary Publishing Company, Limited, announce as ready shortly a new work, entitled, "Essays on Consumption," written by Dr. J. Edward Squire, physician to the North London Hospital for Consumption. An appreciative introduction is contributed by Sir William Broadbent, Bart., M.D., F.R.C.P. Lond., &c.—In our issue of August 25th we reviewed Dr. George Gould's Pocket Medical Dictionary. Appended were the name of the American publisher and the price in terms of American money. Mr. H. K. Lewis, Gower-street, asks us to state that his firm hold the market for the book over here and that the price in this country is 5*s*. net.

THE LATE MR. J. MUDGE.—Mr. James Mudge died at his residence, Hayle, Cornwall, on August 26th. Mr. Mudge, who was born at Bodmin, received his medical education at King's College Hospital and Aberdeen University, qualifying M.R.C.S. Eng. and L.S.A. in 1851. He shortly afterwards commenced practice in Hayle, and was for many years medical officer of health for the local boards of Hayle and Phillack. Mr. Mudge, who was one of the best-known surgeons in West Cornwall, will be much missed in Hayle and the neighbourhood, where he was most popular. The deceased was a prominent Freemason and twice filled the chair of the Cornubian Lodge, being made a Prov. J. G. W. in 1869. The funeral, which took place at Phillack on August 29th, was largely attended.

VACCINATION RETURNS.—At the meeting of the Gloucester Board of Guardians held on August 28th it was reported that the vaccination returns for No. 1 district from July 1st to Dec. 31st, 1899, were as follows: births registered, 179; successful vaccinations, 73; conscientious objections, 20; deaths of unvaccinated children, 19; vaccinations postponed, 7; and children removed, 12; leaving 48 in default.—At the meeting of the Long Ashton (Somerset) Board of Guardians held on August 28th, under the presidency of Mr. F. Weatherly, M.R.C.S. Eng., it was stated that for the six months ending December, 1899, there had been 267 births registered, 161 children had been successfully vaccinated, and 25 had died unvaccinated. There were four postponements and 12 removals, and 55 children remained unvaccinated.—At the meeting of the Devonport Board of Guardians held on August 31st it was reported that during the years 1898 and 1899 there had been 3668 births registered. 1754 children had been successfully vaccinated, and 1020 were unaccounted for. One of the members considered this very unsatisfactory as 50 per cent. of the children were unaccounted for, and eventually a sub-committee was appointed to confer with the vaccination officers upon the matter.

THE annual cricket match between "Parsons and Doctors" which took place recently at Exeter resulted in an easy victory for the medical profession.

PRESENTATION TO A MEDICAL MAN.—On August 24th Mr. James T. Neech, L.R.C.P. Edin., L.F.P.S. Glasg., D.P.H. Vict., of Tyldesley, Manchester, was presented with a silver-mounted set of game and meat carvers by the staff of the Leigh Joint Fever Hospital, Astley, on resigning his appointment of medical officer to the institution to take up the duties of medical officer of health for the county borough of Halifax.

# Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

BEALE, H. R., L.R.C.P., M.R.C.S., has been appointed Junior Obstetric House Physician to St. Thomas's Hospital.

BENNETT, J. H., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Fourth Sanitary District of the Maidstone Union, vice A. Wood, deceased.

BOULTON, A., L.R.C.P. Lond., M.R.C.S., D.P.H., has been re-appointed Medical Officer of Health by the Horncastle Rural District Council.

BOWEN-JONES, L. M., L.R.C.P. Lond., M.R.C.S., D.P.H., has been appointed Medical Officer of Health for the Borough of Carmarthen, vice W. L. Hughes, deceased.

BURFIELD, T., M.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

CLARKE, H. H. R., L.R.C.P., M.R.C.S., has been appointed Assistant House Physician to St. Thomas's Hospital.

CUNNINGHAM, J. F., L.R.C.P., M.R.C.S., has been appointed House Surgeon to St. Thomas's Hospital.

DAVISON, H. E., M.B., B.S., B.Hy. Durh., M.R.C.S., L.R.C.P. Lond., has been appointed Resident Medical Officer to the Newcastle-on-Tyne Dispensary, vice W. Hardcastle, resigned.

DUDGEON, L. S., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Electrical Department of St. Thomas's Hospital.

EDWARDS, T. H., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

ENSOR, C. A., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health for the Tisbury Rural District, vice J. A. Ensor, resigned.

EVE, F. C., B.A., M.B. B.C. Cantab., has been re-appointed House Physician to St. Thomas's Hospital.

FERGUSSON, JAMES HUGH, F.R.C.S. Irel., D.P.H., has been appointed Medical Superintendent Officer of Health for the County Borough of Londonderry.

FLANAGAN, P. J., L.R.C.P., L.R.C.S. Irel., has been appointed Certifying Surgeon under the Factory Acts for the Carney District, County Sligo.

GREENWOOD, ALFRED, M.D., Ch.B., D.P.H., L.R.C.P., L.R.C.S., has been appointed Medical Officer of Health to the Borough of Crewe and Medical Superintendent to the Crewe Isolation Hospitals, vice Meredith Young.

HARRIS, H. G., M.B., B.S. Durh., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to the Paddington Green Children's Hospital, London.

HARWOOD, H. M., M.A., M.B., B.C. Cantab., has been appointed House Physician to St. Thomas's Hospital.

HAWKINS, C. L., M.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S., has been appointed House Surgeon to St. Thomas's Hospital.

HEDLEY, E. W., M.A., M.B., B.C. Cantab., has been re-appointed House Physician to St. Thomas's Hospital.

HEWETSON, ALFRED, M.R.C.S., L.R.C.P. Lond., has been appointed Assistant Surgeon to the Huddersfield Infirmary.

HOWLETT, B. F., L.R.C.P., M.R.C.S., has been appointed Senior Obstetric House Physician to St. Thomas's Hospital.

KILVERT, J. E., L.R.C.P., M.R.C.S., has been re-appointed Senior Ophthalmic House Surgeon to St. Thomas's Hospital.

KINLOCH, R. B., L.R.C.P., M.R.C.S., has been appointed House Physician to St. Thomas's Hospital.

KNOX, R. G., L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the Freshford District of Somerset.

MACKEITH, JOHN, M.B., C.M. Edin., has been appointed Medical Officer to the Exeter Postal Staff, vice J. Moore, resigned.

MARTIN, A. E., M.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S., has been appointed House Surgeon to St. Thomas's Hospital.

MENNELL, Z., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Special Department for Diseases of the Ear in St. Thomas's Hospital.

MORGAN, R., M.D., L.R.C.S. Irel., has been appointed Certifying Surgeon, under the Factory Acts for the Ballyfeard District of the Kinsale Union, County Cork.

NITCH, C. A. R., L.R.C.P., M.R.C.S., has been re-appointed Clinical Assistant in the Special Department for Diseases of the Skin in St. Thomas's Hospital.

POOLE, J. S., M.D. Dubl., has been appointed Certifying Surgeon under the Factory Acts for the Mallow District in the County of Cork.

RUTHERFORD, R. A., L.R.C.P., L.R.C.S. Edin., has been appointed Certifying Surgeon under the Factory Acts for the Manorhamilton District, County Leitrim.

SELOUS, C. F., L.R.C.P., M.R.C.S., has been appointed Assistant House Physician to St. Thomas's Hospital.

SLOSS, WILLIAM, M.B., Ch.B., has been appointed Junior House Surgeon to the Bootle Borough Hospital, Liverpool.

STEVENSON, ARCHIBALD, M.B. Glasg., has been appointed Junior Assistant Medical Officer to Hawkhead Asylum, Crookston.

TAKAKI, Y., L.R.C.P., M.R.C.S., has been appointed House Surgeon to St. Thomas's Hospital.

TAYLOR, T. S., M.A., M.B., B.C. Cantab., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

TODD, CHARLES, M.D., D.P.H. Cantab., has been appointed Assistant Bacteriologist to the Antitoxin Department of the Jenner Institute of Preventive Medicine at Sudbury, Harrow.

WATKINS, J. W., M.D. Edin., M.R.C.S., has been re-appointed Medical Officer of Health for Earlestown and Newton.

WILLS, B. S., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

WINGRAVE, WYATT, M.D., has been appointed Physician to the Central London Throat and Ear Hospital, Gray's Inn-road.

# Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index).*

BELGRAVE HOSPITAL FOR CHILDREN, 77, Gloucester-street, London.—House Surgeon, for six months. Board and residence, with £5 allowance.

# Births, Marriages, and Deaths.

## BIRTHS.

BIDWELL.—On Sept. 5th, at 59, Wimpole-street, Cavendish-square, W., the wife of Leonard A. Bidwell, F.R.C.S., of a daughter.

HAMILTON.—On Sept. 3rd, at Skew Gables, Cole-park, Twickenham, the wife of J. J. C. Hamilton, M.R.C.S., L.R.C.P., of a daughter.

MACPHERSON.—On Sept. 1st, at Henley-on-Thames, the wife of W. H. Macpherson, M.R.C.S., L.R.C.P. Lond., of a son.

MARTIN.—On August 29th, at Cranmere, Cosham, Hants, the wife of Staff-Surgeon J. McCardie Martin, D.S.O., R.N., of H.M.S. *Barfleur*, of a daughter—stillborn.

SIMPSON.—On Sept. 1st, at Kynance, Farnborough, Hants, the wife of Captain J. Tracy Simpson, M.D., R.A.M.C., of a daughter.

WALLIS.—On Sept. 4th, at Welbeck-street, London, W., the wife of F. C. Wallis, F.R.C.S., of a son.

WILLIAMS.—On August 28th, at Port St. Mary, Isle of Man, the wife of Stanley W. Williams, L.R.C.P. Lond., M.R.C.S., of a son.

## MARRIAGES.

HAYMAN—JAMES.—On Sept. 4th, at the Parish Church, Weston-super-Mare, by the Rev. G. Shallcross, rector of East Harptree, William Speed Hayman, M.B. Lond., Thorncliffe, Clapham-park, to Lilian Emma, eldest daughter of W. H. James, solicitor, Fortfield, Weston-super-Mare.

HOWSE—HEAWOOD.—On August 28th, at St. Luke's Church, Torquay, Arthur E. Howse, M.R.C.S., of Falkland Lodge, Torquay, to Ethel Florence Logan, only child of Mr. James Heawood, of Shirenewton, Monmouthshire.

JAGO—ROBERTS.—On Sept. 1st, at St. Clement's, Barnsbury, Thomas Dinnen Jago, M.R.C.S. and L.R.C.P., eldest son of Thomas Jago, surgeon, Arundel-square, Barnsbury, to Annie Florence, second daughter of T. Andrew Roberts, surgeon, of Richmond-road, Barnsbury.

PAYNE—ALLISON.—On Sept. 1st, at St. Saviour's, Croydon, William Henry Payne, M.R.C.S., L.R.C.P. Lond., of Vesta-road, Brockley, S.E., to Ethel Frances Warrell, of Norbury-crescent, Norbury, youngest daughter of the late George Allison, Esq.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Death*

# Notes, Short Comments, and Answers to Correspondents.

## THE WILES OF A QUACK.

DURING the recent fatal illness of a late eminent physician the following announcement appeared in an evening paper: "Sir A—— B——, M.P., is suffering from acute cancer of the liver and there is little hope of his recovery." This appears to have caught the eye of an enterprising quack medicine vendor who had not sufficient knowledge of the *personnel* of the medical profession to be aware of the patient's identity, for there is no allusion to it in the following letter, which was addressed to the House of Commons with a request that it might be forwarded:—

> "DEAR SIR,—Noticing the above clipping I thought perhaps 'twould not be out of place to let you know that cancer of the liver has been cured repeatedly by medicine, and I will be happy to put you in the way of being cured if you feel disposed to depute someone to call upon me by appointment either by wire or letter. I have no object or motive in thus writing you other than a desire to help my fellow-creatures, more especially when laid up by a disease generally accepted as incurable. I am well known to a number of gentlemen of position, among whom are some who are cognisant of my successful endeavours to help my fellow-creatures when laid up by diseases hitherto considered incurable.
>
> "Yours faithfully,
>
> "G. W. ROBERTSON."

It will be noticed that the benevolence of this gentleman towards his fellow-creatures did not take him so far as to induce him to forward a sample of his wares gratis, and therefore we can hardly do him an injustice if we assume that one object of the deputation which he was willing to entertain on behalf of the patient would have been to arrange for a recompense in return for his intervention. While we do not suggest that the cure of cancer of the liver would not be a medical feat deserving recompense, we do protest against ill, and perhaps dying, persons, whose eminence may cause their condition to be a matter of notoriety, being solicited by strangers in this revolting manner. We feel that our protest is hardly likely to remedy the evil. Any effective remedy would not be easy to find, The writer of the letter words his communication with some care; he infringes no law that we are aware of; probably his nostrum would arrive, if purchased, under the cover of a Government stamp, and nothing in his communications would show any pretence of his being medically qualified. And as it is extremely unlikely that he would waste paper and stamps in offering to cure "diseases hitherto considered incurable" unless from time to time his offer were accepted, we cannot expect him to desist from a profitable, if cruel, trade on account of a mere protest. He may send his communication to some poor sufferer, until then ignorant of his or her hopeless condition, and so precipitate the end by shock. He would then be liable to penalties, but the circumstances would probably prevent the relatives from exacting them. We should like to hear from any of our readers whose patients have been honoured with the attentions of Mr. G. W. Robertson.

## THE CARE OF AN EPILEPTIC.

*To the Editors of* THE LANCET.

SIRS,—I should be glad of your advice in placing a young girl, aged 17 years, in a suitable home. She is an epileptic and of weak mind and at times is seized with fits of violence, when she will attack her mother, her sole companion during the day, and kick or even bite, break panes of glass, ornaments, &c., and as she grows stronger is getting quite beyond her mother's control. I have thought of the epileptic colony but do not know the address or I should write for full particulars before troubling you. Your kind assistance will be thankfully received by

Yours faithfully, L.R.C.P. & S. IREL.

Sept. 4th, 1900.

*** Our correspondent had better communicate with the National Society for the Employment of Epileptics. The secretary is Mr. G. Penn Gaskell and the office is at 12, Buckingham-street, Strand, London, W.C. The Meath Home at Godalming might also suit the patient. The address is Westbrook, Godalming, Surrey, and the honorary secretary is Mrs. Leonard Burrows.—ED. L.

## CORONERS' FEES.

*To the Editors of* THE LANCET.

SIRS,—I have recently had to give evidence at an inquest at Ipswich for which I was allowed the usual fee of one guinea for the inquest and one guinea for the post-mortem examination. The inquiry was held on a Saturday. The jury required a post-mortem examination to be made. This I did on the following day (Sunday) and was assisted most ably by Dr. Paterson of Ipswich. As the case was one of injury from some explosive it was unusually prolonged and exhaustive and most carefully conducted, as there was to be an adjourned inquiry in consequence of an official for the Government to attend at the adjourned inquest on the Friday following.

I attended at the offices of the Ipswich coroner at his request to give him a preliminary report of the result of the inquest on the Monday, on which day I was compelled to go to London. And on the Friday following I left London at 10 A.M. and gave my evidence at the adjourned inquest at Ipswich; being kept until the very last witness had given his evidence, I was not able to get back to London (Plumstead) until 11 P.M.—13 hours in all. The coroner, who is a lawyer and who was most complimentary to me, said that we were "very poorly paid as a profession" and "he would have been glad to have paid me a fee of 10 guineas, but they were not allowed to pay any fees for adjournments," and all he could allow me was my out-of-pocket costs for fares, thus leaving me without any remuneration whatever for loss of time, payment for substitute, refreshment *en route*, and loss of a midwifery case whilst away. I claimed 3*d.* per mile each way for fares, but even this was refused and I had to accept a smaller fee.

I am, Sirs, yours faithfully,

Putney, S.W., August 28th, 1900. A. S. MORTON, M.D. Durh.

## WHO PAYS FOR DISINFECTION?

*To the Editors of* THE LANCET.

SIRS,—I enclose my card. Will you kindly oblige me with an answer in your next to the following. W., his wife, and four children go to the seaside in lodgings; about four days after arriving one child is taken ill with scarlet fever and is at once removed to an isolation hospital. W. and the rest of his family return home at once. The sanitary authorities have now sent W. an account for 25*s.* for disinfecting the lodgings and for disinfectants. W. objects to pay on the grounds that he never asked the inspector to call and disinfect and that the disinfection ought to be done free of charge by the sanitary authorities. W. had to pay the lodging-house keeper for the four weeks he took the rooms for, though only occupying them about four days. Can the sanitary authorities make W. pay the 25*s.* for disinfecting another person's house and for the disinfectants?

I am, Sirs, yours faithfully,

Sept. 3rd, 1900. PONTIUS.

*** Unless our correspondent's solicitor advises him to resist the claim we recommend him to pay the 25*s.*, though we recognise that to do so is a distinct hardship. He has a good case upon which to argue that he is not liable, but to attempt to establish the case he must have legal assistance. And he might after incurring further expense fail.—ED. L.

## YEAST IN "PUTRID" OR TYPHUS FEVER.

A CORRESPONDENT sends us some extracts from the *European Magazine* for 1799 and from Buchan's "Domestic Medicine," 1824, giving instances of wonderful recoveries in cases of putrid fever after the administration of yeast. He asks whether the same treatment might not give good results among our troops in South Africa. Yeast was doubtless employed in cases of putrid fever, whatever that term meant, fairly frequently in the early years of the present century and for many years before. It was recommended by no less an authority than Stokes in 1816, but the general results did not come up to the expectations which had been formed. Apparently yeast does exercise a favourable influence in certain forms of streptococcal infection, such as furunculosis, and a correspondent writing in our issue of July 31st, 1852, claimed to have witnessed the good effects of yeast, given in doses of one tablespoonful in water three times a day, in epidemics of boils. It is perhaps possible that the putrid fevers of the older physicians may have been instances of mixed infection, and thus partly streptococcal.

## MARRIAGE OF COUSINS.

*To the Editors of* THE LANCET.

SIRS,—I have lately been consulted as to whether first cousins may marry without fear of damage, mental or physical, to their offspring. The would-be contracting parties are, as far as I know, healthy and there have been no previous intermarriages between their families.

I am, Sirs, yours fathfully,

Sept 4th, 1900. G. C. P.

*** When cousins are healthy and have no proclivity to hereditary disease they may safely marry, but the existence of a strongly-marked predisposition to tuberculous or other taint should prevent such marriages. Marriage with cousins exaggerates the influence of heredity.—ED. L.

## WANTED, A DIAGNOSIS.

*To the Editors of* THE LANCET.

SIRS,—A strong but nervous man showed me about six weeks ago a sample of urine which he had passed three days previously after he had been using a mowing machine for a couple of hours, from 3 to 5 P.M., on one of the hottest days which we had in July. The urine (three days old) seemed to contain blood, but I could not absolutely verify this on microscopical examination. He had no pain or other local symptom at the time or afterwards. A specimen passed on the day on which I saw him contained mucus. On the evening of that day he was sick and was purged and his skin was irritable. No nettle-rash developed and the stomach and bowel symptoms soon passed off on light diet. The later specimens of the urine contained at first a good deal of deposited phosphates, phosphates on boiling, and was iridescent, never alkaline, but never strongly acid, the specific gravity ranging from 1009 to 1020. At times it continued iridescent, deposited phosphates on boiling, was slightly hazy at bottom on standing, but all in a much lessened degree. There were no symptoms suggesting stone apparent. At first I gave him citrate of potash with buchu, later diluted phosphoric acid and nux vomica, with saline purgatives occasionally.

I am, Sirs, yours faithfully,

August 26th, 1900. INQUIRER.

## "THE CORNUTOR OF SEVENTY-FIVE."

*To the Editors of* THE LANCET.

SIRS,—If any reader of THE LANCET happens to possess a copy of a small octavo pamphlet bearing the above title and would be kind enough to lend me the same for a short while I should be very much obliged. There were two editions, each of which was published in 1748. Either of them would suit my purpose, but I should prefer the second.

I am, Sirs, yours faithfully,

Brightwalton, Wantage, Sept. 1st, 1900. GEO. C. PEACHEY.

## UNQUALIFIED PRACTICE.

"M.R.C.S." writes to us as follows: "I have on several occasions been asked by medical friends if surgeons are not allowed to cover or employ the unqualified, in what position are nurses at hospitals where they are constantly in the accident room doing minor surgery such as opening abscesses, introducing sutures, removing and replacing bandages in cases of fracture, &c., without any instructions or supervision—probably in scalp wounds sometimes closing and thereby concealing a fracture which might have been discovered by more knowledge and care."

We hope that there are not many hospitals in which the nurses act as our correspondent describes, "without any instructions or supervision," and if there are even one or two where such practices are carried on, all we can say is that they should at once be stopped. Medical students are specially exempt from any share in the offence of covering, it being taken for granted, as it is taken for granted in the case of nurses, that their work is done under supervision.

*M.B.*—A list of medical teachers will be found in THE LANCET of Sept. 1st, 1900 (p. 717). In our opinion any teacher who is accustomed to coach for the final examinations of the various examining bodies would be found quite competent. Our correspondent had better procure specimens of past examination papers and direct the attention of the tutor selected to the course of study therein indicated.

*L.R.C.S. Edin.*—If our correspondent will consult THE LANCET for Sept. 1st he will find the information which he requires.

*Mr. P. McKay.*—Our correspondent will find the list which he requires in THE LANCET of July 14th, 1900 (p. 143).

*York.*—There can be no objection to anyone who is qualified for it applying for the post.

**COMMUNICATIONS not noticed in our present issue will receive attention in our next.**

## METEOROLOGICAL READINGS.

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

# MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1900, which was completed with the issue of June 30th, and the Title-page to the Volume, were given in THE LANCET of July 7th.

### VOLUMES AND CASES.

VOLUMES for the first half of the year 1900 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

| FOR THE UNITED KINGDOM. | | TO THE COLONIES AND ABROAD. | |
|---|---|---|---|
| One Year ... ... ... | £1 12 6 | One Year ... ... ... | £1 14 8 |
| Six Months ... ... ... | 0 16 3 | Six Months ... ... ... | 0 17 4 |
| Three Months ... ... | 0 8 2 | Three Months ... ... | 0 8 8 |

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

## Communications, Letters, &c., have been received from—

A.—Dr. Aldrich-Blake, Lond.; Professor Clifford Allbutt, Cambridge; Mr. F. J. Allan, Lond.: Anglo-American and Continental Pharmaceutical Co., Croydon.

ABSTRACT OF THE

# Address in Surgery,

ON

# TUBERCULOUS LESIONS FROM A CLINICAL POINT OF VIEW.

*Delivered before the Canadian Medical Association at Ottawa on Sept. 13th, 1900,*

By EDMUND OWEN, M.B. LOND., F.R.C.S. ENG.,

SURGEON TO ST. MARY'S HOSPITAL, AND CONSULTING SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON.

MR. PRESIDENT AND GENTLEMEN,—Though the substance of the address which I have the high honour of presenting to you may entirely fail to arouse in you any measure of satisfaction, yet I think I may claim your kind appreciation for its title. For it gives the assurance that I am not going to ask you, even in your imagination, to pass any of this September day in that gloomy room in which Death is made to deliver up his grosser secrets; nor in that other place where, in an atmosphere of methylated spirit and oil of cloves, you are accustomed to unravel the tangled threads of morbid tissues. My remarks will deal with tuberculous lesions as the surgeon meets them day by day in hospital ward and operating theatre and in private practice. It is a good thing for a surgeon now and then to get away from pathologists and morbid histologists. In recent years there has been, perhaps, rather too much inclination to apotheosise the morbid anatomist, who, standing high in his suit of sable, looks upon the clinical surgeon as if his chief duty were to supply him with material.

In the title of my address are the words "from a clinical point of view," and desiring to emphasise the fact that the word *clinical* related solely to remarks made and work done in the sick-room and in the theatre, I thought it well to call attention to its exact meaning. But on looking it out in "Liddell and Scott," I found to my dismay that κλίνη was not only *that on which one lies, a couch or bed*, but secondarily, a *bier*. I confess that the discovery somewhat disconcerted me. If a *bier* why not a *mortuary table?* At any rate the word "clinical" is of wider signification than I supposed it to be; so that the pathologist might have right on his side when he claimed that clinical instruction, begun at the bedside, and carried, perhaps, into the operating theatre, is not actually complete until he has written the epitaph.

Even on this side of the middle of the dying century, institutions were in existence in which much pathological work was actually done within the walls of the hospital itself. This, of course, we know to have been quite wrong. But surely we have now gone to the other extreme: the pathological laboratory is constantly getting further and further away from its source of supply. The pathologist is no longer a practitioner of medicine, his interest is not in the case but in the subject.

The clinical surgeon has of late, I think, been a little too much under the influence of the experimental pathologist and bacteriologist. When some important surgical problem awaits a solution which cannot be effected in the ward or on the operating table, the clinical surgeon turns to his enthusiastic and obliging friends in the laboratories who, in order to help him, straightway proceed with careful thought and gentle hands to sacrifice upon the altar of Hygeia some mongrel curs or a few of those tailless rodents which, so far as I can see, have been provided solely for the use of the experimental physiologist and pathologist. Then, because such-and-such a thing happens under such-and-such circumstances in the laboratory to the dog or the guinea-pig, the experimental pathologist is apt to assume that in different circumstances it must happen also in man himself.

No one will think, I trust, from what I have said, that I would underrate the work of the experimental pathologist; it certainly is not so, for I well know that it is to these workers that we owe our knowledge of the precise cause of diphtheria as well as of tuberculosis—of tetanus and erysipelas, and of many other serious diseases. And knowing the cause we have been enabled in many cases greatly to influence the course of the disease by treatment. Indeed, it would be almost impossible to over-estimate the practical value of experimental laboratory work both to the profession and to the public. Nevertheless, there are some of the public who, in their ignorant well-meaning, and in their well-meaning ignorance would once and for all stop such beneficent research. But stranger still, there are some members of our own profession in England who also try to get in the way of scientific progress. Fortunately, however, they have not the power of doing much harm.

Much of my clinical work has lain amongst senior students: I come in contact with them just as they have left the laboratories and are proceeding to put what they imagine to be the "finishing touches" upon their professional education. They have spent many delightful hours in a pathological laboratory and in a white cotton smock; they have cultivated and even tamed bacilli; they have seen how potent they may be for evil, and they are firmly of opinion that if once such germs gain access to a suitable spot in a suitable individual, nothing short of the most vigorous surgical measures can suffice for the eradication of the disease and for the emancipation of the host. This is the students' bacteriological faith and except they act up to it their patients cannot be saved. Many young practitioners also hold that faith. Where do they learn it? Not in clinical surgery.

But is the outlook in advanced tuberculous disease necessarily so hopeless in the absence of active surgical treatment? To answer this very important question I will instance an imaginary case of a young man who a year or so previously hurt his back in a fall at a gymnasium. He has now pectoral neuralgias, and dull pains between his shoulder-blades and in his back, which have probably been ascribed to "rheumatism." Eventually the discovery is made that the third and fourth dorsal spinous processes are unduly prominent, and it is evident that the bodies of those vertebræ have undergone complete tuberculous disintegration. The disease is close behind the arch of the aorta, and the surgeon is unable to get at it. He cannot scrape it, and he cannot even irrigate it with germicidal lotions. I believe that there are some surgeons who would attack it if they could: *rien n'est sacré pour un sapeur;* but fortunately he cannot possibly get at it. What, then, is to be the future of this patient? Is he going to die the death, as the guinea-pig would in the laboratory? Most certainly not. He is to be made to lie about, in the sun if possible, and he is probably going to get well. Everyone here has acquaintance with such an individual, or if he does not know him personally he has seen him in the street. He is rather a short man with peculiarly high, square shoulders, and with a boss between them. And not only has he long since outgrown his tuberculous disease without any operative assistance whatever, but could we see him in his own home we might not improbably find him—and I say it with some regret—surrounded by a crowd of apparently healthy sons and daughters.

Such a case is one of great clinical importance; it shows that a man with an undoubted tuberculous lesion of the first magnitude can completely recover without having undergone any operative procedure whatever. At the end of the nineteenth century it is somewhat unusual for any patient with any surgical affection to be allowed the opportunity of showing what he can do without submitting himself to operation, so that such an account as that which I have just instanced becomes not only important but actually interesting. One rarely hears speak now of the *vis medicatrix Naturæ:* surgical zeal has apparently rendered it not only obsolete but superfluous.

Another instance of the favourable course which undoubted and severe tuberculous disease may run without active surgical interference, is seen in the case of old-standing hip-joint disease, the boy actually "growing out of his trouble." The disease, let us suppose, began at that period of life when it is customary to send a boy to school, and his school-life was frequently interrupted and was continuously clouded by the affection. But he is now a young man at college, and though he walks lame and is precluded from taking an active part in athletics, still he is vigorous, and he has evidently and completely triumphed over his disease. I am not sure that I have in clinical work ever before used the specious expression, "growing out of a disease"; and possibly I might not do so now if I thought that there were any students or unqualified persons present, for its adoption

might prove unfortunate or even dangerous. It is a rather favourite expression, however, amongst parents and other ill-informed persons when confronted with a child with a tuberculous lesion. Would they expect a garden to grow out of its weeds or a field grow out of its thistles? No; it is a popular superstition, but, like most erroneous beliefs, it is founded on a substratum of truth. For, as a matter of fact, many patients do "grow out of" tuberculous disease.

I have failed to discover that iodoform is of any peculiar value in the treatment of tuberculous lesions. At any rate I have long since discarded it, and I have not noticed any falling-off in the results of my practice in consequence. Iodoform is an irritant and a poison; and it is apt to be septic, as germs can grow upon it. Some time since a lady was sent to me for my opinion about a tuberculous ulcer of the anus which a practitioner had long been treating with iodoform. She earnestly begged me to consider if I could not recommend some other local application, as she said that the smell of the yellow powder rendered her "socially objectionable." This was for her a very serious matter, as she kept a fashionable boarding-house, and whilst many members of her household seemed to notice the peculiar odour, some few of her young men "paying-guests" actually appeared to recognise the drug itself.

### THE FORCIBLE STRAIGHTENING OF CARIOUS SPINES.

The direct treatment of the angular deformity resulting from tuberculous disease of the spine is a subject that a few years ago was thrust somewhat vigorously upon us, not only by articles in the medical papers but by the reproduction of photographic representations of ghastly clinical procedures in the pictured journals of the lay press. This is hardly the way in which one would expect solid surgical work to be advanced.

To affirm that the forcible straightening of carious spines must needs be unsurgical simply because it is a reversion to the ways of the bone-setter would be unfair, for the blundering bone-setter sometimes did good by chance. But at any rate he experienced none of that sense of responsibility which a surgeon must feel when he is proposing to straighten a tuberculous spine. It is obvious that in straightening the angle the tuberculous ulcer of the vertebræ must be widely opened out, and that if the neural arches have been already cemented together this rigid support must be broken across. And, supposing that this is done, and that the patient survives the risks which are inseparable from the procedure, will the widened osteal ulcer duly heal and the neural arches again become solid? Possibly so. But—and this is the point—will there be no further recurrence of the hump?

Though I should be grieved to stand in the way of surgical advancement, I do not mind getting in the road and temporarily impeding traffic whilst we are taking time to consider the route, and are assuring ourselves that the stream of surgical practice is going in the right direction. My opinion is that the deformity of Pott's disease does not lend itself to operative treatment; that forcibly to interfere with it is to thwart Nature in her good attempts at effecting a curative consolidation in her own way—and Nature's ways, as a rule, are not unworthy of our respectful recognition. I think, further, that in a short time we shall hear very little about the method.

The humped back of spinal disease is, of course, an opprobrium, and it is small wonder that the surgeon is anxious to efface it. But if he had given proofs of such laudable anxiety at the beginning of his treatment of the case he would probably have had no hump to deal with. I have no hesitation in saying that, even at the present time, the treatment of spinal disease in its earliest stages is too often half-hearted and sometimes actually blameworthy. It may be urged by way of excuse that at the very beginning of spinal disease the symptoms are so equivocal that the practitioner hesitates even to whisper his opinion, lest the disappearance of the symptoms should suggest that after all he is an alarmist. He knew that the girl had symmetrical pains in her chest, abdomen, or legs; he knew that she got easily tired at play, or that she was inclined to loll and lie about when others were full of activity, and that, regardless of nursery manners, she persistently sat at meals with her elbows on the table. He suspected spinal disease; he even told the parents that the girl should be kept quiet. He may actually have gone so far as to sketch out a plan of treatment which was designed to secure a certain amount of rest, but he was slack in seeing that even this small measure was carried out. In short he had not the courage of his opinions. So the case was allowed to drift.

Oh, for the spirit of Lady Macbeth who called out to her weak-kneed spouse and fellow-practitioner—

> "Infirm of purpose! Give me the daggers!"

I am a great admirer of Lady Macbeth though I am fully aware that her character is not faultless. She was not the sort of person, perhaps, to be trusted with the dissection of tuberculous glands from the neck or of operating on a case of torticollis, but how splendid she would have been in the treatment of early spinal disease. There would have been no half-measures with her.

### THE TREATMENT OF VERTEBRAL CARIES.

If a practical surgeon were asked what is the proper treatment of early spinal disease he would unhesitatingly say "rest." Yes, absolute and uninterrupted rest. But there is only one way of insuring such rest for a child, and that is by making him lie flat in bed. As I shall set forth directly, he is not to be kept actually in bed all the time; but in every case the treatment is at any rate to be commenced by imprisoning him in a pillowless bed. This, I feel sure, is the only way of successfully inaugurating the treatment of rest. But it is of little use if, when in bed, the patient is allowed to roll about, to sit up for his meals, or to hang over the side of the bed in order to pick up a dropped toy. The details of the treatment must be seriously considered, and the medical man must make it his business to see that they are loyally and thoroughly carried out. He must not content himself merely with giving his instructions; the parents will very likely want careful looking after as well as the boy, or else as soon as the medical attendant has left the house, or at any rate after a short period of rest, the boy will probably be allowed to do pretty well what he likes, and so the case will quietly drift. What the circumstances demand is the presence of a sort of clinical policeman in the house—in the shape of a hospital nurse.

I know that there are all sorts of schemes, corsets, apparatus and braces (as my American friends call them) for treating spinal caries without keeping the child flat. But they are all wrong; wrong in theory and wrong in practice; and if they could be cast into the bottomless pit, and every case of spinal disease could from the beginning be treated by continuous rest in the horizontal position, there should be no more of those unsightly humps to invite speculative interference. Of course, I do not include in my anathema Phelps's box splint, the double Thomas's splint with head piece, or any form of cuirass which takes the child in bodily and keeps him flat. Indeed, the design of each one of them is well-nigh perfect; but what I want utterly and severely to condemn is the modern ambulatory treatment of spinal caries. Indeed, I think it probable that after all the stir about the new treatment of hump-backs by forcible straightening has subsided, a most important beneficial clinical outcome will be that every surgeon will feel himself compelled to be far more careful in the adoption of patient and efficient prophylactic measures in the early days of the disease. Hear what Sir Benjamin Brodie says upon the subject. This is the sentence at the very beginning of his valuable chapter on the "Treatment of Caries of the Spine." "From the first moment, therefore, in which the nature of the case is clearly indicated, the patient should abandon his usual habits, and be confined altogether on his bed or couch."[1]

Naturally one turns also to see what Percivall Pott has to say upon the question of the treatment of the disease which bears his honoured name. And it is somewhat of a disappointment to find him so taken up with the subject of the "Palsy of the Lower Limbs" which follows destruction of the bodies of the vertebræ, that apparently he has not the inclination to discuss general measures. But it is all delightful reading; and even to-day it is brimful of clinical instruction. What a relief it is to read a chapter or two of Pott, or Brodie, or Chassaignac after one has been poring over the pages of some modern text-book in order, as the saying is, to "keep abreast with the times"! Pott seems to put his red velvet sleeve around one's shoulders and to draw one aside from the bustling crowd of the "busy practitioners" (in whose peculiar interest modern text-books are quaintly said to be written), and to talk to one in the delightful manner of those whose literary style has not been spoilt by the habit of counting words on telegraph forms, or

[1] Observations on the Diseases of the Joints, 1850, page 342.

of compiling "copy" of precise length, and in a limited time, for medical publishers!

However, Pott has a few remarks to make about the treatment of the later stages of spinal disease, but I am afraid that they will not prove acceptable to most modern surgeons any more than my own poor remarks on that subject may do. Still, it is a great pleasure to know that one is in good company the while Pott is talking about the treatment by "spinnal supports" and "steel boddices," and as I am telling you what he says I feel his velvet sleeve leaving my shoulders and actually passing around my neck. He says that though the use of these pieces of machinery is so general, and the vulgar prejudice in their favour is so great, he has long been convinced of their perfect inutility; and, moreover, that he is satisfied their effects are mischievous.

Speaking generally, the acceptance of a simple, unromantic clinical method makes a far more serious demand upon the parent's or the patient's confidence than does the bidding of him to do some greater thing. This is understood and acted upon by the quack who, merely to create an impression, inserts in a lengthy prescription some rare and perhaps rubbishing ingredient which he thinks the apothecary will be unlikely to have in stock; who writes out a fussy dietary with unworthy attention to detail, and who, having failed to effect the promised cure, endeavours to preserve an unenvied reputation by sending his confiding patient to some far-distant watering-place. In spite of education people love quackery now just as much as they did in the time of Elisha; and the higher they are in the social scale the more, apparently, they seem to hanker after it. The brief clinical record which we have of the tuberculous lesion of the Syrian Lord Roberts admirably illustrates these points, for,

> "Naaman was wroth, and went away, and said, Behold, I thought, He will surely come out to me, and stand, and call on the name of the Lord his God, and strike his hand over the place."

No; if he was to undergo the water-cure it certainly should not be in a muddy Israelitish stream; he knew of a couple of spas in Damascus which were really high-class! "So he turned and went away in a rage." But being "a great man" he was not obstinate; so he changed his mind, followed out the instruction to the letter, and, to his intense delight, attained the reward which sometimes falls to those who do exactly what their medical attendants tell them. At this point, so far as this address is concerned, the clinical aspect of the case of Naaman ends; but it still contains an important lesson from a public point of view. For when the gallant officer found that his cure was complete he went straight to his good doctor—whilst the tear of gratitude was still in his eye—and begged his acceptance of a substantial and appropriate reward for the great service which he had rendered.

Here, in eastern Canada, it would especially ill become me to speak lightly of the value of cod-liver oil in the treatment of the disease under consideration, but perhaps I may humbly suggest that there are other remedies which may be looked to in the circumstances. As a matter of fact I am a great believer in the value of the oil, but I would not against his will insist on a child taking a dessert-spoonful or even a teaspoonful of it three times a day—as the manner of some is. So forced down, it is apt to upset the stomach as well as to cause diarrhœa, and it may then be found floating upon the surface of the dejections. We are all apt to get too much in the habit of prescribing medical and dietetic treatment by routine, ignoring the fact that constitutions are not equally made to pattern. You have heard of that submissive patient for whom Sir Andrew Clark had laid down a very particular and strict regimen which ended up as follows—"and after dinner one cigar; not a strong one; a single Manilla cheroot." In answer to the illustrious physician's inquiry, a week later, as to how the dietary had answered, the unhappy patient, whilst replying that he was certainly better, pleaded to be let off the cheroot, which had invariably had the result of dispossessing him of his dinner! Possibly, however, after all, it was that cheroot which had played the most important part in effecting the gentleman's improvement.

Cream, butter, bacon, and other fatty foods are all good for tuberculous patients, but I think that there is nothing quite so valuable as cod-liver oil. And if a patient assures me that he *cannot* take it, I often manage successfully to administer it after breaking up a conspiracy amongst his olfactory, optic, and pneumogastric nerves. He probably confesses that he likes sardines; so, without his becoming aware of the trick, I have the preservative cotton-seed oil emptied away, and keep the sardine-box filled with fresh cod-liver oil, of which every day he unconsciously takes a substantial amount. For a tuberculous infant I order systematic inunction of the limbs and body with cod-liver oil every evening after the warm bath. I fully understand that this is apt to make the child "socially objectionable," but this is overlooked when the mother finds that the child is improving, and steadily increasing in weight. A steady increase in weight is a splendid clinical omen in the treatment of tuberculous or quasi-tuberculous patients.

### PROPHYLAXIS.

The extermination treatment of tuberculosis is a subject in which every member of the community should be encouraged to take a personal and intelligent interest. It is a great mistake to allow it to be regarded merely "a doctor's question." And to wage a successful war of extermination the attack should be begun right early. It is a question which is of vital importance for the nursery, the schoolroom, the dwelling-house, the store, the office, the barrack—in fact, it concerns every department and every period of life. The disease is everywhere, and its eradication is, therefore, a matter of concern to everyone. It has not yet been shown that the offspring of tuberculous parents are born actually tuberculous, but it is beyond question that they are very prone to inherit a peculiar physical condition which renders their tissues an easy prey to the germs of the disease. The family history of many patients who at the threshold of life become the subjects of enlarged glands, or of chronic affections of the bones or joints, gives incontrovertible evidence of there being a marked hereditary disposition in the matter of tuberculosis.

So comes the question, ought there to be a law preventing those who are undoubtedly tuberculous taking upon themselves the responsibility of parentage? There are some who would answer this affirmatively and without hesitation. But what would the Church in general say to it, and what would the tuberculous curate in particular say to it? He would tell us that he reads in the very beginning of his Book that he is to "Be fruitful and multiply"; and, to do him justice, it must be admitted that in England, at any rate, he does his best to carry out this instruction to the very letter. But let him finish the injunction—Man was to be fruitful that he might *replenish* the earth. Now, though I do not claim to be in possession of peculiar knowledge on this point, I cannot think that the Architect of the Universe who "saw everything that He had made and, behold, it was very good," could have desired that this beautiful world was eventually to be stocked with so large a proportion of tuberculous rubbish. I am fully conscious of the fact that in suggesting the desirability of preventing the marriage of tuberculous subjects I am advancing a somewhat extreme measure, but surely the subject enters very largely into the question of prophylaxis. It is one, moreover, that will have to be deliberately approached and dealt with some day, and that, perhaps, soon. I do not think that our Houses of Parliament as at present constituted will be anxious to occupy themselves with an attempt to solve this question, vast as its Imperial importance is, but I think that the county councils which we have lately established through England might find the task not uncongenial. The question is fully as important as that of water-supply, or of protection from fire, or of the isolation of infectious disease, each of which is already in their grasp. Indeed, I think that it falls in under the last heading. And what scope it would afford for discussion!

You will remember that when Horatio and Marcellus joined Hamlet on the platform after the appearance of the ghost, and showed great anxiety to know what had been the subject of his remarks, Hamlet tried to put them off by telling them that his communication had been something of quite a commonplace nature, on which Horatio ejaculated:—

> "There needs no ghost, my lord, come from the grave,
> To tell us this."

I do not know what space the "perturbed spirit" had traversed in order to deliver his address to the unhappy prince, but I have travelled about 4000 miles to deliver mine. And if you feel inclined to suggest that there was no need for one to come so far to tell you that which I have just unfolded—that it is commonplace, and by no means worth my long journey or your short one—I shall conclude with Hamlet's retort,

> "Why, right; you are i' the right;
> And so, without more circumstance at all,
> I hold it fit that we shake hands and part."

As a matter of fact, I have not, like the ghost, temporarily escaped for the purpose of this communication from a place where sulphur, burned in the open, is the ordinary domestic fuel, but I am here in response to a kind and highly flattering invitation from yourselves. I had, indeed, made arrangements for spending an autumn holiday which certainly did not include two weeks of sea-sickness; but when I received your President's command (for so I regarded your invitation) I at once scattered my personal plans and considerations to the winds and decided to accept it. And let me tell you that coming to Ottawa is not to me like going amongst strangers, though it is my first visit here; it arouses in me a feeling somewhat like that experienced by a man who is taking a homeward journey, for my father was a Canadian. From my infancy I have had pictured to me, and have been encouraged to interest myself in, your forests and rivers, your orchards and wide fields of waving corn, your green pastures and still waters, and your lingering snows (kindly notice that I have put the snows *last*). I have also constantly heard from my childhood of the intense loyalty of the peoples of this great and fertile country, and of the loving devotion of its sons and daughters to that dear Lady who is, indeed, a Mother to us all.

Lastly, let me tell you that your complimentary invitation came to me just after those dark days of trial in which an ambitious, a cunning and an unscrupulous race had been endeavouring for ever to overwhelm us. Dark indeed were those days; but darker still would they have been had we not known that your strong-limbed and keen-eyed sons were standing by us in our time of need. It is certainly not for a humble individual like me to presume, or to attempt, to say what the feeling of undemonstrative England may be towards Canada: I allude to this and to other circumstances only that you may in some measure see with what pride I accepted your invitation, and in order that you may the more fully appreciate the sincerity of the thanks which I herewith tender you for thus directing my course to Ottawa, with an inclination Eastwards to Nova Scotia—and to Halifax—where, in 1812, my good father was born.

# An Address

ON

# THE PREVENTION AND TREATMENT OF POST-PARTUM HÆMORRHAGE.[1]

BY JOHN W. BYERS, M.A., M.D., M.A.O. (HON. CAUSÂ) R.U.I.,

PROFESSOR OF MIDWIFERY, QUEEN'S COLLEGE, BELFAST; EXAMINER IN OBSTETRIC MEDICINE IN THE ROYAL UNIVERSITY OF IRELAND; VICE-PRESIDENT OF THE OBSTETRICAL SOCIETY OF LONDON; PHYSICIAN FOR DISEASES OF WOMEN TO THE ROYAL VICTORIA HOSPITAL, BELFAST; CONSULTING PHYSICIAN TO THE BELFAST HOSPITAL FOR SICK CHILDREN; AND PRESIDENT OF THE NORTH OF IRELAND BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

GENTLEMEN,—Post-partum hæmorrhage may be defined as hæmorrhage occurring after the birth of the child and either before but usually after the delivery of the placenta. If it occurs within a period of 24 hours it is said to be primary, but for purposes of discussion we may say clinically that post-partum hæmorrhage occurs soon after delivery or, if later, before the usual period that the medical attendant leaves his patient believing her to be safe.

## AMOUNT OF BLOOD LOST.

It has been stated that as a result of careful estimates made in lying-in hospitals the average amount of blood lost in childbirth is one pound, but while this may be accurate scientifically, yet for practical purposes it would convey little information to tell a medical man engaged in private practice that when the blood lost at a confinement by one of his patients exceeded, say, from 16 to 20 ounces he was to regard it as a case of post-partum hæmorrhage. In practice we soon come to know that every patient is a rule to herself as to the amount of blood she loses during the birth of her child. Some lose more, others less, and it is probable that, as Dr. Giles has pointed out, there is a "physical temperament" characterised by copious pigmentation and the brunette complexion in which the tendency to hæmorrhage is greater, and among such the normal amount of loss at the time of labour would be above the average. A woman may be said to suffer from post-partum hæmorrhage when she has a sudden excessive loss of blood after childbirth or when a slighter amount continues to flow, and when at the same time there is either uterine inertia or traumatic lacerations of the parturient canal, the effect of the hæmorrhage being shown by her constitutional condition, as evidenced by her appearance (variations in pallor) and by her pulse (rapid, low tension and the intervals between the beats not well marked).

## PATHOLOGY.

In order that we may treat post-partum hæmorrhage it is necessary to know what are the usual pathological conditions present in cases of bleeding setting in immediately after delivery, and the causes may be grouped under two heads. A.—Hæmorrhage due to uterine atony, the bleeding in these cases arising from the uncompressed vessels in the placental area. B.—Wounds of any part of the parturient canal without any necessary inertia.

By far the most numerous cases fall into Group A; indeed, some would restrict the term "post-partum hæmorrhage" to cases of atony of the uterus, but for purposes of diagnosis and treatment I shall also have to speak of cases arising from traumatic lacerations. However, I ask your attention mainly to the first division:—

### A.—CASES OF HÆMORRHAGE AFTER DELIVERY WITH A RELAXED UNCONTRACTED UTERUS.

In the majority of labours post-partum hæmorrhage sets in without our having had any warning to put us on our guard against its occurrence, but in some cases our suspicions as to the possibility of our having to deal with such a serious complication may have been aroused beforehand. The following are the conditions which may lead the accoucheur to suspect the onset of post-partum hæmorrhage.

I. *History.*—(1) Hæmorrhage at a previous confinement; (2) rapidly succeeding pregnancies, especially met with amongst the poor, time not being given for the uterine muscle to assume its normal condition; (3) a combination of want of exercise and the taking of too much food and stimulants, as seen among the better classes; (4) elderly primiparæ; and (5) patients with pre-existing metritis.

II. *During pregnancy.*—(1) Over-distension of the uterus (twins, hydramnios, &c.); (2) presence of a tumour in the uterus (myoma) preventing uterine contraction; (3) albuminuria; (4) extreme mental depression seen often in cases following the death of the husband; and (5) excited vascular system, especially towards the end of pregnancy.

III. *During delivery.*—1. The character of the pains in the second stage of labour. "The pains are of this kind—they are strong and quick; they do not gradually culminate into a strong pain and subside again, but they are sharp, quick, and cease almost suddenly, and the intervals between the pains are long in proportion to the length of the pains."[2] 2. A pulse keeping rapid towards the end of delivery, with low tension and of a jerking nature. This state of pulse is quite different from that met with in nervous women at confinement or in those who have taken chloroform. In both of these conditions the pulse may also be quick, but there is a distinct interval between the beats and there is evident vascular tension.

By some it is thought the administration of chloroform during a confinement predisposes to the occurrence of post-partum hæmorrhage. At the Nottingham meeting of the British Medical Association in July, 1892, I read a paper entitled, "Does Chloroform Promote Post-partum Hæmorrhage?" in which I endeavoured to show that this anæsthetic has no effect in causing post-partum hæmorrhage provided that in all cases care is taken not to effect delivery too rapidly and also to manage the third stage of labour according to modern teaching. Subsequent experience has confirmed me in the view I have stated, but I need hardly

[1] Introductory Address to a discussion on "The Prevention and Treatment of Post-Partum Hæmorrhage" in the Section of Obstetrics and Gynæcology, British Medical Association, Ipswich, August 3rd, 1900. An abstract of this address and of the debate which followed upon it have appeared in THE LANCET (August 25th, 1900, p. 606 et seq.), but the importance of the subject warrants a fuller publication.

[2] Whittle: Brit. Med. Jour., Sept. 27th, 1873.

say that in all cases in which in obstetric practice chloroform is given to the surgical degree a competent person should be asked to administer the anæsthetic.

### PROPHYLAXIS OF POST-PARTUM HÆMORRHAGE.

There is no complication met with in obstetric practice of which it can be more truly said that its treatment is its prevention, and the best proof of this aphorism can be found in the circumstance that while students and medical men in the early years of practice dread the condition, as they get more experience they become less fearful of it and really meet it less frequently. I propose to speak first of the prophylactic measures to be used to prevent its occurrence in every case, and subsequently to say something as to the measures to be adopted under those special conditions which I have mentioned as leading us to suspect its onset.

### PROPHYLAXIS TO BE ADOPTED IN ALL CASES.

The two measures which should be adopted in every case to prevent post-partum hæmorrhage are—(1) the proper management of the third stage of labour; and (2) the important principle never to deliver in the absence of pains.

1. *The management of the third stage of labour.*—Of no condition in obstetric practice may it be said with greater truthfulness that "meddlesome midwifery is bad" than of the management of the third stage of labour. This is due partly to the teaching of Credé, but still more to inaccurate knowledge as to what occurs in the uterus after the birth of the child. There are two factors in the third stage of labour—(*a*) the separation, and (*b*) the expulsion of the placenta with the membranes. Nature should be allowed to separate the placenta, and then if she is not equal to the second task the accoucheur can assist in helping her to expel the already separated placenta. The great mistake is an attempt made at once by the obstetrician to express the placenta from the upper or contractile part of the uterus—a line of practice liable to be followed by retention of membranes, post-partum hæmorrhage, and even septic poisoning—instead of waiting until certain signs indicate that nature has separated it. For the sake of clearness and because of its enormous importance as a preventive of hæmorrhage after delivery let me point out the best method of managing the third stage of labour.

As soon as the head of the child is born the left hand of the accoucheur is placed on the woman's abdomen over the fundus of the uterus, the ulnar edge of the hand looking towards the vertebral column. The child's eyes are wiped and a finger ascertains if the cord is round its neck. During the subsequent birth of the child the left hand of the accoucheur follows down the fundus. Immediately after the child is born the woman is turned on her back, the advantage of this most important step being twofold, as it enables the uterus to be easier and better controlled by the accoucheur's hand, while it prevents (especially in multiparæ) the entrance of germ-laden air through the relaxed vulva. As soon as pulsation has ceased the nurse ties the cord, one ligature being placed in the usual way near to the child's abdomen, the other close to the vulva of the mother (care being taken gently to draw down the cord so as to leave no loop in her vagina). The hand of the accoucheur never leaves the fundus (except in the case of a child born in white asphyxia, when the medical man must look after it and the nurse takes his place in controlling the fundus). No attempt should be made to massage or stimulate the uterus; all that is required is simply to control the uterus with the hand and to ascertain when the placenta has separated. This can easily be diagnosed by the following signs: 1. A sudden rising up of the uterus which may have previously been largely in the pelvis. 2. A swelling detected above the pubes due to a bulging forward of the lower uterine segment. It is very much in the position of a distended bladder and is sometimes mistaken for it. 3. Greater mobility of the uterus. 4. Expulsion of a few more inches of the cord as shown by the fact that the ligature placed at first close to the patient's vulva has now advanced from that position a few inches.

The separation of the placenta, as indicated by these signs, takes place in about from 20 to 30 minutes. When once the placenta has separated and has left the upper active and contractile portion of the uterus then firm pressure is made by the hand of the accoucheur over the fundus during the height of a pain and the placenta is expelled out of the lower uterine segment and vagina; the nurse then takes charge of the after-birth, gradually turning it round and round to get the membranes thoroughly away. The hand of the accoucheur still controls the uterus, and while he is doing this the nurse floats the placenta and membranes in a basin of water so that he can see if there is any lobule of placenta left behind or if there is a piece of chorion wanting, indicating the presence of a placenta succenturiata. Supposing the examination of the placenta and membranes shows there is nothing left behind, the nurse bathes the patient's vulva with a mercurial lotion (all blood, &c., being removed), applies a pad wrung out in antiseptic lotion, and the binder is put on, but the accoucheur never lets go control of the uterus until this is completed. In this way the uterus is left in a state of permanent retraction.

2. The other important measure as a prevention of post-partum hæmorrhage is not to deliver in the absence of pains. As examples of the abuse of this principle I may cite such a condition as "secondary uterine inertia" where a labour comes to a standstill. The pains cease and the woman and her friends (Smellie's "Gossips") urge the medical man to deliver her. It may be she is well on in the second stage, but her pulse is quiet and her uterus on abdominal examination is relaxed and there is no rise of temperature. The medical man yields, tired it may be after sitting up all night and anxious to visit other patients; he easily slips on the forceps and delivers, but later severe hæmorrhage sets in, the uterus not having contracted, and the woman is in imminent peril. Here the proper line of action should be to give a dose of opium; the woman will then fall asleep and after a time pains will come on again and she will probably deliver herself without any assistance.

Another example of the terrible mistake of delivering in the absence of pains is afforded by the way cases of placenta prævia are sometimes managed. It is well known that one of the best methods of treating placenta prævia is by bimanual version, a foot being brought down so as to dilate and plug the lower part of the uterus with the child's leg and thigh. Too often it is forgotten that time must be allowed for uterine pains to come on and deliver the child after it has been turned; the delivery is hurried after the child has been turned, and, as a result, hæmorrhage occurs from an atonic uterus, while the forced delivery, by tearing the tissues of the lower part of the uterus (which, owing to the implantation of the vascular placenta, are as soft as blotting-paper), causes also a bleeding due to traumatic laceration of the parts.

### PROPHYLAXIS TO BE ADOPTED IN SUSPECTED CASES OF POST-PARTUM HÆMORRHAGE.

When from the symptoms I have mentioned we suspect the occurrence of hæmorrhage after delivery the following precautionary measures should be adopted:—1. During pregnancy the patient should be advised to take exercise and keep her skin (baths) and bowels (purgatives) acting. She should avoid all stimulants of any kind and if there is albuminuria a milk diet should be enforced. 2. During confinement the fœtus should be delivered slowly, its birth being followed down by the hand on the fundus, and it is good practice (provided the head or breech presents) to puncture the membranes when the os is nearly fully dilated. By this measure the pains are increased in energy and it also favours tonic contraction of the uterus after expulsion of its contents. Further, from the very onset of labour the patient should be kept lying, and as soon as the os is fully dilated I have found the practice recommended by the late Dr. McClintock of giving two teaspoonfuls of liquid extract of ergot most useful.

In cases where I suspected the occurrence of post-partum hæmorrhage I have prescribed for a couple of weeks before delivery 10 grains of chloride of calcium thrice daily. This practice gave good results, but whether the medicine or the careful management of the third stage of labour deserves the credit it is, of course, difficult to say. Dr. Lombe Atthill of Dublin in cases where from the experience of previous labours he anticipated post-partum hæmorrhage or where in the progress of tedious labours the uterus became exhausted, so that he suspected hæmorrhage after delivery, gave in the former case for three weeks before the expected labour a mixture of liquor strychniæ with infusion of ergot, adding iron if the patient was anæmic and hydrochloric acid if she was plethoric. He gave this mixture for from seven to ten days; then, after ceasing its administration for 48 hours, he let the patient continue to take it. The mixtures are as follows: liquid extract of ergot, two drachms; solution of

strychniæ, one drachm; diluted hydrochloric acid, two drachms; infusion of ergot to six ounces, a measured tablespoonful to be taken thrice daily. In anæmic women the hydrochloric acid was replaced by one drachm of iron and ammonium citrate. In the latter case (exhausted uterus in a tedious labour) he recommends a dose of ergot with 10 drops of liquor strychniæ in the first dose and five drops in the next, if necessary. Endometritis in a married woman at the child-bearing age should be carefully treated.

### TREATMENT OF POST-PARTUM HÆMORRHAGE.

As there is hardly any complication met with in midwifery needing greater pluck and more resourceful and prompt action on the part of the attendant it is good practice in all confinement cases to see, as the second stage of labour is advancing, that everything is conveniently ready, such as hot water, the douche, with double-current intra-uterine tube (Bozeman's or Budin's), &c. The accoucheur, fortified in this way, acts with much greater self-reliance should hæmorrhage suddenly set in Supposing the placenta and membranes have all come away and that then suddenly bleeding sets in with a relaxed inert uterus, what should be our line of practice?

1. I think the first measure to be adopted is external uterine massage. By this means the uterus is stimulated to contraction, clots are expelled, and often this method is sufficient of itself to arrest the hæmorrhage.

2. Should this plan fail then I recommend the use of hot water. A double-current instrument (Budin's or Bozeman's) should be employed, and it is a great advantage at the same time to draw down the uterus by catching the anterior lip of the cervix with a vulsellum forceps. Certain precautions in the use of hot water are necessary. 1. Temperature. In maternities a bath thermometer is of use as indicating the proper temperature (118° F.) to be used, but in private practice the best rule is to use the water at that temperature which the hand immersed in it will bear. 2. Amount. The hot water should be used in large quantities. 3. The intra-uterine tube should be passed up to the fundus so that the whole inner surface of the cavity is bathed. 4. Antiseptic. Some use a little creolin in the hot water. I prefer salt—a teaspoonful to the pint. Never use any corrosive in the hot water, the objection to it being that, owing to the open state of the uterine vessels, absorption takes place rapidly with the risk (I have seen its occurrence) of mercurialism. Cold water should not be employed. It is not sterile and its low temperature has a prejudicial effect on the anæmia, while the hot water is distinctly stimulating.

3. The introduction of the hand into the uterus. As there is no operation I believe so dangerous to a parturient woman as the introduction of the hand of her attendant (owing to the admitted difficulty of rendering it aseptic) into the uterus, this practice should only be done when the indications are clear. If hæmorrhage sets in before the placenta comes away and if, owing to adhesions, external abdominal massage fails to expel it, then the hand must be introduced to separate and withdraw the placenta. Again, if a lobule of placenta or a piece of outlying after-birth is retained (I have mentioned the signs indicating both of these conditions) the hand should be introduced to remove the retained parts which prevent by their presence the uterus contracting on its open vessels. After the hand has been withdrawn the uterus should be carefully douched with a hot creolin lotion. In the absence of the clear indications I have mentioned the use of the hand inside the uterus is, I believe, bad practice. No doubt it stimulates the uterus to contract, but hot water will do this equally well, and there is not the same risk of septic poisoning as when the hand is introduced.

4. Should the preceding measures have failed then we may try bimanual compression, but my own experience of it is that it is very fatiguing to the accoucheur and trying to the patient; and I prefer—

5. Gauze plugging of the uterus. A word about its technique. You may, as the text-books teach, need three lengths of four or five yards, each from three to four inches broad, but I have been struck with the fact that when the uterus is drawn down with the vulsellum in many cases very much less of the gauze is needed. The plan I can recommend from personal experience is to carry in your obstetric bag one of Dührssen's sealed tins of sterilised iodoform gauze. This tin takes up little room, it can be opened quickly (as a tin of Brand's essence), and it contains sufficient gauze to plug the uterine cavity. I get it through Fannin, the instrument maker in Belfast, from Berlin. Great care should be taken to plug the uterus tightly up to the fundus. The hold given by the vulsellum forceps allows sufficient counter pressure when you are packing the cavity of the uterus. The gauze acts by stimulating the uterine muscle to contract, but also by insinuating itself into the mouths of the bleeding vessels and so directly compressing them.

6. Drawing downwards the uterus. Should we meet a case where, notwithstanding the gauze packing, hæmorrhage continues I think we should first (on the assumption that our previous technique has been at fault) remove the gauze, wash out the uterine cavity with a creolin douche, and re-apply—packing very firmly—the gauze. If notwithstanding the hæmorrhage again returns I would strongly recommend the firm drawing down as far as possible of the uterus with tenaculum forceps passed through the lips of the cervix. This method acts, I think, by kinking and compressing the uterine arteries, as is seen often in the operation of vaginal hysterectomy. In such circumstances Professor Schauta of Vienna thinks atheromatous vessels are present in the placental area. He advises laparotomy in hospital practice, or in private practice eversion of the uterus into the vagina by pressure on the fundus, so that the bleeding vessels may be caught, or an indiarubber ring (as recommended by Kocks) or a gauze bandage may be fastened round the everted uterus so as to cut off the circulation. The compression should not be maintained for more than six hours to avoid gangrene, and Professor Schauta prefers that the vessels should be caught directly rather than that pressure should be applied to the whole uterus. When the bleeding is stopped the uterus is to be re-inverted. I have no personal experience of this method: I simply mention it on the authority of the distinguished Viennese obstetrician.

7. Injection of iron. I have not used the injection of perchloride of iron solution for the past five years. It is a remedy not without danger; it causes a certain amount of superficial injury of the uterine wall, which forms a suitable nidus for the growth of germs; and if it fails plugging cannot be done owing to the effect that the iron has on the tissues. I have been told that gauze plugging has replaced the use of iron in bad cases of post-partum hæmorrhage in the Rotunda Maternity Hospital.

The treatment which I have mentioned applies to cases of uterine inertia giving rise to hæmorrhage after the delivery of the placenta. Should bleeding set in before the after-birth is delivered pressure should be at once used to bring it away, and if this fails the hand should be introduced to separate and withdraw the placenta. Should a portion of the placenta remain or a piece of membrane, or should there be the suspicion of a uterine tumour, the hand must also be introduced for diagnosis and treatment. In all such cases the uterus should afterwards be most carefully douched out with a hot creolin lotion.

### B.—POST-PARTUM HÆMORRHAGE FROM WOUNDS OF ANY PART OF THE PARTURIENT CANAL.

This division includes the class of cases described by the older obstetricians as post-partum hæmorrhage with a contracted uterus. The wounds or lacerations may occur in the perineum, the crura of the clitoris, or the vessels of the bulb, the vagina (of greatest importance when the wounds are at the upper and posterior part often involving the large vessels of the cervix), the cervix, or the uterus itself.

A word or two about the diagnosis of the source of the bleeding in these cases.

1. *The history.*—It is after forceps or unaided labours that vulvar or vaginal wounds are most apt to occur, while lacerations of the cervix are more usually met with in breech and turning cases.

2. *Examination.*—The best time to distinguish between atony of the uterus and a wound of the parturient canal as a source of bleeding is when, by massage, you have made the uterus to contract. If the hæmorrhage is from uterine inertia the blood is suddenly driven out of the uterus, but in lacerations there is a continuous oozing, the uterus remaining contracted. If the uterus is washed out by means of a double-channelled tube the return fluid is clear if there is no uterine inertia, while if there are lacerations blood is still seen to flow at the sides of the tube from vagina or vulva. If blood comes from a wound of the vulva ocular inspection will demonstrate its source and its florid

colour; if with a contracted uterus there is no wound of the external parts, then a careful examination of vagina and cervix will show where the wound is in cases of hæmorrhage.

### TREATMENT OF LACERATIONS.

The perineum if torn should be stitched up. Hæmorrhage from a wound of the vascular anterior part of the vulva (often produced by one of the blades of the forceps) may be stopped by a gauze pad and pressure or a suture may be passed by a curved needle. Wounds of the vagina must be stitched, and if the cervix is lacerated it can be drawn down and sutured, or a gauze plug may be applied.

A very rare cause of post-partum hæmorrhage is a wound of the uterus, or it may be due to a previously existing intra-uterine tumour which has been injured and torn during labour. Here diagnosis and treatment follow upon a careful digital exploration of the uterus. If possible the tumour should be removed and a gauze plug applied. In the rare cases of hæmorrhage due to a tear of the uterus gauze plugging should be used.

### THE AFTER-TREATMENT OF POST-PARTUM HÆMORRHAGE.

When the hæmorrhage has ceased the subsequent anæmia demands most careful treatment. The patient should be kept quiet, her head low, the lower part of the bed being raised to facilitate the weak circulation. Subcutaneous injections of ether and strychnine are most useful, but our sheet anchor is saline transfusion, experiments having shown that in animals bled almost to death they will recover if a normal saline solution is introduced into the circulation. If the heart gets something to act on it can be kept going until the natural vascular fluids have time to form again. The saline solution (one teaspoonful of salt in a pint of warm sterilised water) may be introduced direct into the veins; this is the best method, but it takes time and often cannot be done without skilled assistance. On the other hand, the solution may be given by enema or, which is I think better, into the tissues by means of a large hollow needle and funnel which are connected by tubing (the instrument makers now provide the apparatus). Half a pint may be injected into the tissue under each breast. The amount of saline fluid to be used or re-used depends on the patient's condition—two, four, or six pints. It should be injected slowly at a temperature of 98° F. and we should continue it until the pulse gets slower and increases in volume. In addition to these measures in the treatment of the anæmia the patient should be encouraged to take nourishment (such as concentrated meat juices, milk, &c) which is quickly absorbed.

# THE CHEMICAL EXAMINATION OF GASTRIC CONTENTS.

BY FRANK SHUFFLEBOTHAM, M.A., M.B., B.C. CANTAB.

DURING the last 20 years no branch of medical science except bacteriology has received the attention of so many observers as the chemical examination of gastric contents. Two causes may be assigned for the rapid advances made in this period. The first, and perhaps the more important, is the introduction of the use of the stomach-tube, an instrument which enables us to study the various processes of digestion at its different stages. Previously to the adoption of this tube all we knew about digestion was obtained from observations made upon cases of gastric fistulæ and of vomiting. We can thus understand why our knowledge on this point was so small. The second cause results from the researches of the great French philosopher, Berthelot, who was the first to place the chemical analysis of stomach contents upon a firm scientific basis.

The processes of digestion are very often examined after giving test meals and the stomach contents are drawn off at different moments after the meal. When making a series of systematic analyses it is best to adopt a definite routine in this procedure. All kinds of meals have been suggested by different physicians and the greatest extremes have been adopted. Some have found that 10 ounces of dry bread and half a pint of water have served every purpose they wished, while others have prepared a menu of six courses probably with a view of overcoming the instinctive prejudice which a patient shows to having his stomach interfered with in so unpleasant a manner. The simpler the meal, however, the better, and in the cases considered in this paper the test meal consisted of eight ounces of bread cut in thick slices and covered with a little butter, together with half a pint of weak tea containing sugar but no milk. Two hours later the stomach contents were drawn off.

In a particular case it is always as well to consider whether anything will be gained by giving the patient the test meal and drawing it off from the stomach. In a case of long-standing dilatation of the stomach due to carcinoma pylori there is always a great deal of residual fluid which has fermented, so that it would be futile to give a test meal with the hope of learning anything about the digestive processes going on. If we are desirous of making investigations on this point the stomach must be washed out until the washings are clear and sweet. Then the test meal may be given to advantage.

There is a practical point worth mentioning with regard to drawing off the gastric contents. In some instances after the test meal has been given it may be impossible to draw off anything whatsoever. Sometimes kneading the abdominal wall over the stomach region or getting the patient to cough will cause ejection of the stomach contents through the tube, but when these methods are without avail just sufficient water should be poured down the tube to convert it into a syphon. This quantity of water should be measured, and in making a quantitative estimation of the constituents of the specimen a corresponding correction should be made.

The gastric contents, when obtained, will probably contain a certain amount of solid material which has great avidity for the acids present. If we were to filter straight away some loss of acid would be entailed, but this is avoided by shaking up the gastric contents in a stoppered bottle until the solids are broken into small pieces. The material is then filtered with a corrugated funnel and an analysis of the filtrate made.

### THE ANALYSIS OF THE FILTRATE.

An alkaline reaction is only found when the patient has been taking alkaline drugs or when a pancreatic fistula is opening into the stomach. An acid reaction may be due to free hydrochloric acid alone or to organic acids—lactic, acetic, butyric, or, rarely, to the presence of acid salts; but the commonest cause of all is hydrochloric acid in combination with proteids. I would lay special stress upon the last-named cause as it is a point overlooked in many of the standard works on the subject and also by a great number of investigators. In all I have examined 200 specimens of gastric contents, but have found absolutely free hydrochloric acid on one occasion only. This was a specimen from the

Clinical Research Association which Dr. F. G. Hopkins asked me to examine. Dr. Hopkins has found free hydrochloric acid several times in specimens sent to him for analysis. Free hydrochloric acid and free lactic acid are never present together.

The presence of free acids and hydrochlor-proteids can be shown in two ways. (*a*) By means of Congo red. A piece of filter paper is dipped into a saturated aqueous solution of Congo red and allowed to dry. This changes from red to blue when brought in contact with free hydrochloric acid, free organic acids, hydrochlor-proteids, or any combination of them. (*b*) By means of benzo-purpurin. The test is applied in a similar way to the previous one, but the colour changes from purple to black under the same conditions as above. Now the free acids which may be present are hydrochloric acid, lactic acid, acetic acid, and butyric acid, and of these the two latter are volatile.

*Distinguishing tests for free hydrochloric acid.*—Many tests have been proposed from time to time for the detection of free hydrochloric acid. A great many are very delicate when applied to aqueous solutions of hydrochloric acid but are untrustworthy when used for the purpose of detecting the acid in stomach contents. Without exception, they are based upon colour reaction. The test which I have always applied and which I believe to be the most elegant as well as the most reliable was first introduced by Gunzberg. A test solution is made up as follows: phloroglucin, two grammes; vanillin, one gramme; absolute alcohol, 30 cubic centimetres. This reagent when not in use should be kept in the dark, as otherwise changes may take place which will render the test inaccurate. To perform the test a couple of centimetres of the stomach contents are placed in a porcelain dish, and two or three drops of Gunzberg's solution are added. We now evaporate slowly on a water bath (not to dryness), and should free hydrochloric acid be present a characteristic rose-red ring appears around the dish just above the level of the liquid which is due to the production of red crystals. There can be no mistake about the colour when it is obtained.

Another test to which I call attention is known as the tropaolin test. A solution of tropaolin 00 in alcohol and water is used for this purpose. When the solution is concentrated it possesses a reddish-yellow colour which, when in contact with mineral acids, changes to a characteristic reddish-pink. This test is not always reliable. Its accuracy depends upon the quality of the tropaolin from which the solution is prepared. This substance varies a great deal according to the chemist from whom it is obtained, and even the same chemist often fails to make a substance which possesses identically the same properties each time.

*Hydrochlor-proteids.*—I have already stated that only one specimen of gastric contents which I have analysed contained free hydrochloric acid, but it must not be inferred from this that the acid has not been secreted by the gastric epithelium. Hydrochlor-proteids were present in every case, and it is to this point I wish to draw special attention. We desire to know whether the acid is being secreted or not, and if the former be the case in what quantity. Considering the amount of proteid material present in the food we cannot wonder that free acid is most often not found. As soon as the acid is secreted it unites with the proteid to form hydrochlor-proteids. These bodies will react to the litmus, Congo red, and benzo-purpurin tests, and with an aqueous solution of silver nitrate they will give a white flocculent precipitate which is soluble in ammonia solution. They can be titrated by means of standard alkalies, but the constituent hydrochloric acid cannot be detected by means of Gunzberg's test. We thus see that the hydrochloric acid of the stomach contents may be either free or in combination with proteids. The mere fact of its absence, as determined by Gunzberg's test, should be no source of alarm. It is only when we fail to find acid proteids that we know that hydrochloric acid is not being secreted. Speaking generally we may say that gastric juice does not contain free hydrochloric acid in the true chemical sense of the term. We have proof of this in the experiment of Bernard, who shewed that a very weak solution of hydrochloric acid would dissolve oxalate of lime but that gastric juice possessed no such property. Again, Blondlot proved that gastric juice does not decompose calcium carbonate, while the most dilute solution of free hydrochloric acid decomposes this body at once. Berthelot[1] inferred from his experiments that the hydrochloric acid of the gastric juice behaves as if it were united with a feeble organic base, such as leucin or peptone, and not as if it were in a free state. Now the process of digestion can go on without the presence of free hydrochloric acid. This can be shown by the following experiment which I have devised. A fairly concentrated aqueous solution of egg albumen is taken and a known quantity of a standard solution of hydrochloric acid is added to the extent of 0·25 gramme per 100 cubic centimetres. If the egg albumen be in sufficient quantity this solution will not give the characteristic colouration with Gunzberg's reagent, showing the absence of free hydrochloric acid, and yet, on the addition of pepsin, peptone is formed after the product has been kept at a constant temperature of 37° C. for five or six hours. Should the solution of egg albumen be very weak, on adding the same amount of hydrochloric acid and applying Gunzberg's test we might have an indication of the presence of free acid. For this test to give a positive result the hydrochloric acid must be more than sufficient to combine with all the proteids present, and this applies to albumoses and peptones just in the same way as to albumens. But time is an important factor in the artificial production of acid proteids. Were some two or three hours allowed to elapse before applying the test we might find that all the acid had gone into combination with the proteids and that although immediately after its addition the hydrochloric acid was more than sufficient to combine with the proteids yet after the lapse of this period of time the above combination had taken place.

*Test for lactic acid.*—For this purpose a solution is made up which is known as Uffelmann's reagent. It consists of 10 cubic centimetres of a 5 per cent. carbolic acid solution and 20 cubic centimentres of distilled water. To this is added one or two drops of solution of perchloride of iron and an amethyst blue colouration is obtained. The solution should be prepared fresh each time as it does not keep. In the presence of lactic acid the blue colouration is changed to yellow; in that of acetic acid to a brownish tint. Hydrochloric acid has no effect on this reagent. The brownish colouration due to acetic acid is not at all reliable and may not be obtained even when the acid is in large quantities. There are no good qualitative tests for acetic and butyric acids in the stomach contents.

## QUANTITATIVE ANALYSIS OF GASTRIC CONTENTS.

The object of a quantitative analysis is to determine in the first place the amount of hydrochloric acid present, either free or combined with proteids, and in the second place the amount of organic acids, which will indicate whether fermentative changes are taking place in the organ or not.

We should first estimate the total acidity of the filtrate from the stomach contents. 20 cubic centimetres are a convenient quantity to use for titration. If it be colourless or pale yellow, as it often is, there is no need for dilution, but should the filtrate be of a dark colour it will be necessary to add water until the tint has almost disappeared. A saturated alcoholic solution of phenol-phthalein is the best indicator to use, and two or three drops are ample for any titration. The advantages of phenol-phthalein over litmus are that the colour-change at the critical point is so definite as to be easily appreciated even by the uneducated eye and, secondly, that the operation can be carried out in the cold, and boiling is not, as in the case of litmus, necessary to ensure an accurate result. A decinormal solution of sodium hydrate is the alkali against which the acid is titrated. The result is best expressed in terms of hydrochloric acid. For instance, suppose 10 cubic centimetres of decinormal solution of sodium hydrate be required to neutralise 20 cubic centimetres of the gastric contents (1 cubic centimetre of decinormal sodium hydrate solution being equivalent to 0·00365 gramme of hydrochloric acid) the total acidity of 20 cubic centimetres of gastric contents is equivalent to 0·0365 gramme of hydrochloric acid, or the total acidity of 100 cubic centimetres of stomach contents to 0·182 gramme of hydrochloric acid. This is the most convenient way of expressing the acidity and it is the one generally adopted by investigators on the subject. It should be borne in mind that this is not to say that the acidity is 0·182 per cent.

The presence of free hydrochloric acid not being necessary for the digestive processes our method of estimating this acid should be so chosen as to take account of that part of the acid which is physiologically effective—that is to say, the part which is combined with the proteids—albumens, albumoses, and peptones—found in the stomach contents. It is mainly due to the investigations of

[1] Annales de Chimie et de Physique, quatrième série, tome xxvi., p. 396.

Berthelot that we are enabled to separate the organic acids from free hydrochloric acid and hydrochlor-proteids and to estimate each in an accurate manner. Berthelot found that on shaking an aqueous solution of any organic acid with ether and allowing the two fluids to separate part of the acid passes into the ether, while the remainder clings to the water. The ratio between these two parts he proved to be a constant quantity—the co-efficient of partage—the value of which is a fixed characteristic for each particular acid. All organic acids behave in this way to a considerable though variable extent. Inorganic acids when agitated with ether are not thus affected.

It is generally believed that ether will not extract all the lactic acid found in the gastric contents, but by performing the estimation in the manner which I am about to describe a determination can be obtained which possesses sufficient accuracy to serve every clinical purpose. 20 cubic centimetres of filtered stomach contents are placed in a stoppered cylinder and 30 cubic centimetres of ether are added. The cylinder should then be shaken vigorously for 20 minutes. Then it should be placed away for several hours, or it may be left all night, after which the shaking process should be repeated for another 20 minutes. This mode of procedure is very efficacious in removing the lactic acid. In some experiments which I have performed I added a known quantity of a standard solution of lactic acid to some specimens of vomit, and after treating them in the manner indicated above the yield was never less than 90 per cent. of the acid which had been added. Similar results were also obtained when I added the lactic acid to hydrochlor-albumen which I had artificially prepared. Again, in many determinations which I have made I have extracted with ether four or five times, but if the above course were adopted for obtaining the first extract no trace of lactic acid could be found in the subsequent extracts.

The ethereal extract is drawn out of the cylinder by means of a pipette and placed in a porcelain dish along with a little distilled water. The ether is evaporated over a water bath and the lactic acid passes into the distilled water and can be titrated with a decinormal solution of sodium hydrate, phenol-phthalein being used as the indicator. This gives the amount of free lactic acid. What remains in the cylinder should be gently boiled for a few moments to drive off whatever acetic or butyric acid be present and then titrated in the same way. This will yield the total amount of physiologically-effective hydrochloric acid. Both these results are best expressed in terms of hydrochloric acid, so that an easy comparison may be made with this acid. If the sum of lactic and combined hydrochloric acids be the same as the total acidity we may assume that acetic and butyric acids are absent. A quantitative estimation of these two volatile acids can be obtained by distilling a known volume of gastric contents and titrating the distillate with a standard alkali.

### DIAGNOSTIC SIGNIFICANCE OF THE VARIATIONS OF HYDROCHLORIC AND LACTIC ACIDS.

I will first consider the case when the amount of physiologically-effective hydrochloric acid is normal—i.e., when about 0·22 gramme per 100 cubic centimetres are present and there is no lactic acid. This condition may indicate a normal state of affairs, or at least the absence of any serious structural lesion of the stomach. Such a result is of the greatest practical importance in cases of vague gastric symptoms which may accompany almost any internal disease. When all the symptoms point to the stomach the occurrence of normal acidity indicates nervous dyspepsia or some intestinal trouble. In chronic gastritis we find diminished secretion of hydrochloric acid, and since the subjective symptoms of this disease and nervous dyspepsia are very similar the examination of the stomach contents materially assists us in differentiating the one from the other. Naturally there is no hard-and-fast line. Lessened hydrochloric acid may occasionally occur in nervous dyspepsia, very rarely it may be absent, and the normal amount is not unfrequently found in atony of the stomach. When we find a constant diminution in the production of hydrochloric acid, with no evidence of any fermentative changes, as evinced by the presence of lactic acid, we may suspect chronic gastritis, but the same condition may occur in cases of gastric ulcer, atony or dilatation of the stomach, or sometimes in nervous dyspepsia. Patients suffering from incipient carcinoma may not secrete the normal amount of hydrochloric acid, but in these cases lactic acid may be found to be present.

An increase in the secretion of hydrochloric acid is found in a considerable number of patients suffering from gastric ulcer. In one case which I examined the amount of physiologically-effective hydrochloric acid was 0·6 gramme per 100 cubic centimetres of filtered stomach contents, and in a second case it reached as high as 0·58 gramme in 100 cubic centimetres of filtrate. Boas describes some cases where the acid was altogether absent, and says that this condition occurs sometimes in advanced chronic gastritis, gastric neuroses, and cancer. I believe that Boas refers to *free* hydrochloric acid, although in his paper no distinction is made between free acid and hydrochlor-proteids.

The conditions which favour the formation of lactic acid are stagnation of the gastric contents and absence of free hydrochloric acid. The lactic acid bacillus which is responsible for the formation of the acid is reported by many observers to be killed by free hydrochloric acid, although the contrary opinion is held by Ewald. Lactic

acid has been proved to be absent in innocent stomach affections, such as chronic gastritis, atony, &c., even in the faintest traces.

The absence of lactic acid does not absolutely exclude carcinoma, as it may be understood that the conditions favourable to the formation of this acid are not found in every case. Yet, in view of the statistics on the point, the absence of lactic acid is strong evidence against the existence of cancer. This should be borne in mind in a large class of doubtful cases of chronic gastritis where the constitutional symptoms—emaciation, the general appearance of the patient, and the diminished secretion of hydrochloric acid—lead us to suspect malignant disease.

The absence of free hydrochloric acid was demonstrated in all the above cases, but, as the table shows, physiologically-effective hydrochloric acid could be found without exception in all cases. This was a variable quantity and varied in the same patient from time to time. We also observe that when the stomach is washed out and a test meal given there is more physiologically-effective hydrochloric acid and less lactic acid than is found in vomit.

Lactic acid was present in all the cases on some occasion or other. The largest amount I have found is that quantity which is equivalent to 0·12 gramme of hydrochloric acid per 100 cubic centimetres. This was found in Case 6. In Case 1 and Case 11 it disappeared entirely after repeated washings and in all but Case 3 it was found in the stomach contents when the patient was admitted to the hospital. Six days after admission, however, in this case lactic acid was found to the extent of 0·02 gramme per 100 cubic centimetres. expressed as hydrochloric acid. There was no mistake about the diagnosis as the growth was removed by operation. Out of 21 cases examined by Boas lactic acid was present in 20 and Ewald found it in 22 out of 24 cases. Boas states that he did not find hydrochloric acid in any of his cases, from which I infer that he is referring to *free* acid.

In conclusion, something may be learnt by examining the vomit and stomach contents of patients suffering from diseases other than those of the stomach. In both anæmia and Bright's disease there is a deficiency of physiologically-effective hydrochloric acid. In heart disease there seems to be a difference of opinion, some believing that there is no change, while others hold that there is diminished secretion of hydrochloric acid. I have examined the stomach contents of 10 patients suffering from heart disease and have found that the amount of physiologically-effective hydrochloric acid was lessened in all of them. This is of importance from the point of view of treatment, for under these circumstances digestion can be artificially aided by the administration of suitable drugs.

Guy's Hospital, S.E.

## A CASE OF TOTAL GASTRECTOMY.

BY DR. VIEIRA DE CARVALHO.

THE patient was a woman, aged 46 years, a native of São Paulo, Brazil, and was examined by me for the first time on March 25th, 1900. She was a weak, almost cachectic mulatto, who said that she had suffered from stomach trouble for years, these troubles becoming much worse during the last six months. Lately it had become impossible for her to get nourishment, since on swallowing anything she was seized with acute gastric pains, followed after some hours by vomiting of the food taken, mixed not infrequently with dark blood. Her condition becoming daily worse she resolved to enter the hospital.

She was extremely emaciated, weighing only 31 kilogrammes (68 lb.), but showed outwardly nothing else worthy of note. Palpation revealed the presence of a tumour of about the size of a turkey's egg in the epigastric region on the right side, close to the costal margin. This tumour was moveable, painless even under pressure, and did not seem to give the patient much trouble. Examination of the patient, the history of the case, and the gastric symptomatology convinced me that it was a case of malignant tumour of the pylorus, and I resolved to operate as soon as possible, my intention being to perform gastro-enterostomy. I therefore had the patient prepared for the purpose of operating on her the next day. The preparation consisted of general antiseptic bathing, covering the entire abdominal surface with moist salicylated cotton, ordering a free purge, and total abstention from food for 12 hours prior to the operation, keeping up the strength with alcoholic stimulants. I know that it is the practice of some eminent surgeons to wash out the stomach with antiseptics before operations on this organ. I am not in favour of this procedure, as it causes fatigue and prostration; a patient already weakened by frequent vomiting should not be harassed by the introduction of the Faucher tube. Moreover, I was sure that the stomach would contain no food at the time of the operation, as any that might have been taken would be rejected by the repeated vomiting. I also consider the antiseptic value of washing out a cancerous stomach to be purely theoretical.

Before the operation the patient had a weak, slow, but regular pulse, 60 to the minute; the respirations were 20. Everything being in readiness she was chloroformed by my colleague, Dr. Mattoso. I then made a median incision embracing the region between the xiphoid cartilage and the umbilicus. The abdominal cavity being opened I endeavoured to confirm the diagnosis and ascertain the exact site of the lesion. I saw that there was a malignant tumour of the pylorus, with slight adhesions to the neighbouring organs affecting the greater part of the lymphatics of the stomach. In view of this state of things I gave up the idea of a simple gastro-enterostomy and began to think of a total gastrectomy, in imitation of Professor Carl Schlatter.[1] Having resolved upon this procedure I began to isolate the tumour, cutting, away the omentum between ligatures, carefully uncovering the part of the duodenum not involved, breaking up an adhesion between the tumour, the duodenum, and the head of the pancreas. The adhesions were broken up at the cost of a slight laceration of the pancreatic gland causing a hæmorrhage which was controlled by ligat ng *en masse* with catgut. The tumour and the duodenum being freed I secured this part of the intestine with a Kocher clamp five centimetres below the limit of the neoplasm; a second clamp compressed the pylorus close to the tumour. As I separated the tumour from its adhesions and drew it out I isolated with antiseptic gauze the peritoneal cavity from contact with the diseased organ to be removed to avoid any accidental contamination. Between the two clamps I divided the duodenum through the sound tissues and with corrosive sublimate gauze I disinfected carefully the cut surfaces and the exposed mucous membrane of the intestine. This done, I gradually isolated the stomach from below upwards and from right to left, cutting the peritoneal folds between the clamps, extirpating at the same time the lymphatic ganglia involved, which were numerous. Having freed the stomach from its ligaments I made strong traction downward, bringing the cardiac end as low as possible, and close to the diaphragm I applied to it a Kocher clamp; a little below I placed a second clamp and between the two clamps I cut through the cardiac portion of the stomach. This part of the operation was very difficult, as the right lobe of the liver, very large in this patient, embarrassed my movements. In consequence of having been obliged to apply the clamp just as I did the section of the stomach was slightly oblique; later when the sutures were applied the diameters of the pylorus and the cardiac end of the stomach did not correspond. After careful disinfection of the cut surfaces and of the exposed mucous membranes I commenced the suturing. It was difficult to bring together the two extremities that were to be united. I made the suture with fine silk, in a double row, as advised by Hartmann[2] and Terrier—a process too well known to need describing here. The suturing being completed, the parts united and the whole neighbourhood were again disinfected with a solution of sublimate of moderate strength (1 in 1000). The isolating pieces of gauze were now removed as were also the clamps. On account of the powerful retraction of the œsophagus the recently joined parts were drawn immediately into the abdominal cavity. I then cleansed the peritoneum and closed the abdomen with triple sutures, one above the other. The operation lasted an hour and twenty minutes, leaving the patient in a state of profound shock, with the pulse almost imperceptible, the respiration superficial, and the skin covered with cold, clammy sweat. The means employed to restore her were successive injections of ether, caffeine, and strychnine, hot applications, and placing her in a position with

[1] For Professor Schlatter's full account of this case see THE LANCET, Jan. 15th (p. 141) and Nov. 19th. 1898 (p. 1314).

[2] See Dr. Hartmann's letter on p. 840 of this issue of THE LANCET.

the head lowered. As soon as the circulation began to improve I made an injection of one and a half litres of artificial serum. The effect of the serum was rapid and in a few hours the condition of the patient was encouraging. I ordered nutritive enemata every six hours. In the evening the condition of the patient was good. She was perfectly conscious; the respirations were normal, the extremities were warm, the skin was moist, the pulse was strong but very rapid (140 to the minute), and the temperature was 36·7° C. Small doses of alcohol (Todd's mixture) were ordered.

On March 28th the patient's general condition was good. Her pulse was strong, 140 per minute; the respirations were 20 per minute; and the temperature was 37·4°C. 400 grammes of normal urine were passed. Three nutritive enemata per day were prescribed, with small doses of milk. As the patient complained of intense thirst I ordered Vichy water *ad libitum* in small doses. On the 29th her general condition continued good. Her tongue was clean, her temperature was 37°C., her pulse was 120, and her respirations were 20 per minute. 900 grammes of normal urine were passed. Nutritive enemata were continued with small doses of milk and broth. The patient complained of hunger. Her tongue was clean. On the 30th her general condition was good, her tongue was clean, her temperature was 37° C., and her pulse was 120. 800 grammes of urine were passed. Nutritive enemata, milk, broths with somatose, Vichy water and alcohol were continued. On the 31st there was nothing new to be noted. Her temperature was 37° C. and her pulse was 120. 900 grammes of urine were passed. The patient continued to complain of hunger. On April 1st her general condition was good. Her tongue was clean, her pulse was 110, and her temperature was 37° C. 900 grammes of urine were passed. She had two copious movements of the bowels, the fæces being firm and yellowish, with a few coagula of milk, indicating good digestion. On the 2nd her general condition was good. The pulse was 120. 900 grammes of urine were passed and there was a small movement of the bowels. Her diet was continued as before. On the 3rd her general condition was excellent and there was nothing new to record. The dressings were now removed and it was found that primary union had taken place. The superficial sutures were then removed. Food was ordered to be given in small quantities every two hours. On the 4th all was still going on well. The patient had a ravenous appetite and begged for more solid food. She wished at any risk to eat a mixture of beans and flour. Examination of the removed stomach showed that the operation was reasonable, for besides a tumour ulcerated at the pyloric end and extending upward over the great curvature of the stomach there were numerous ganglia involved in sundry parts of the organ.

In giving this account of what I judge to be the first total gastrectomy done in Brazil I have no other than a strictly scientific end in view. I am of those who think there is no merit in being the first to repeat an operation, however rare. Surgical processes and difficulties do not vary with the latitude. At all events, I think it right and proper to record this new case in the interest of the bibliography of the subject. It raises to four the number of successful total gastrectomies, three being recorded in the masterly work of Hartmann and Terrier on the subject published at the end of 1899. Later, should my patient survive, I intend to present a detailed work on the case, for the absence of the stomach opens a wide field for the study of digestion. Who knows how much we may have to reform our knowledge of the subject, from the sensation of hunger to the digestion of meat; from the need of gastric hydrochloric acid to the function of the pancreatic juice?

São Paulo, Brazil.

## HYSTERICAL SOMNOLENCE AND STATES OF DOUBLE CONSCIOUSNESS.

BY ETHEL M. N. WILLIAMS, M.D. LOND., D.P.H. CAMB.

THE study of the abnormal phenomena of consciousness found in connexion with hysteria and allied states of mental enfeeblement throws, I think, much light on those states of double and multiple personality which are so mystifying at first sight. In these strange conditions the same individual seems to live at different stages of his existence under two or more different forms. He differs in character, in knowledge, and in powers. Often the person of one phase has no knowledge of the life and affairs of the others. He calls himself by another name, he repudiates acts which he performed, and he is ignorant of persons and of affairs with which in another state he was perfectly familiar. He is apparently, in all things except the outward form, another man. Suddenly it may be memory has been lost, all his old recollections have been for the time obliterated, while a new life, a new memory, a new ego have commenced for him. After the lapse of a longer or shorter time a kind of awakening takes place; he returns to his first "normal" condition while the intervening second state is apparently wiped out. The two lives may alternate without being confused through many years. Other states may be added to these, and as many as four or five may alternate with one another in this way.

It is easy to see how in a less scientific age a belief in the supernatural nature of such phenomena would be certain to arise. Persons subject to such alterations of personality were looked upon either as possessed by devils or as inspired by God. They were either burnt as witches or were honoured as oracles. In either case they were looked upon as possessing powers and knowledge not possessed by ordinary mortals. The different treatment depended usually upon whether their pronouncements were pleasant or the reverse to those in power.

These changes in personality are, we know, dependent upon, and caused by, changes in consciousness. Personality is built upon a highly developed consciousness with the idea of the ego superadded. This consciousness is made up of memory and character—character itself being largely built up from, and modified by, memory. It is the events of a man's past life—or rather the memory-images of those events—that have, at any rate to a large extent, made him the man he is. Delete any considerable part of the memory store of any man and you will have made him a different person, for you will have taken away the ideas and motives which coloured his life and directed his conduct. I am prudent, for I have learnt in the school of experience the results of imprudence; I am cheerful or depressed, courageous or cowardly, my courage or my cheerfulness being largely dependent upon my memory store.

These memory-images are of course not always on the surface of the field of present consciousness. In the deeper strata of the consciousness of each one of us there are hosts of old memory-images believed to be lost, for we cannot call them up at will into that surface of our minds which forms the field of present consciousness; yet they still live within the limits of our memory, though not within those limits of which our present consciousness is cognisant. In normal mental life the elements composing the field of consciousness are constantly changing, yet those changes are usually small—at any rate they are never of the nature of mental upheavals and never so sudden as to cause a change in the idea of the ego. Yet suppose that by some means the present level of our consciousness were suddenly broken up, so that the memory-images which compose it were submerged, while other memory-images forming representations which belonged to a past stage in our existence, when they supported possibly a vastly different personality, were to rise up and replace them. We must remember that the memory-images which present stimuli are awaking in our minds are not the only ones those stimuli might awake. Then, if the memory-images thus thrown upon the shores of our minds—the flotsam and jetsam of our mental shipwreck—formed a fairly complete picture of that mind at some past stage in its career, the personality reproduced would be that past self divested of all powers and thoughts, and therefore of all character built upon them, which have been acquired during the years which have intervened, and re-endowed with ideas and powers which have been lost through the lapse of time. For those ideas and powers were not really lost but merely buried and hidden.

This condition is, in my experience, a very fairly common one to meet in cases of hysteria and allied states of mental enfeeblement, though it is by no means always recognised. The clinical picture is often something of the following. The patient has complained constantly both of insomnia and also that she (for it is usually a woman) is always drowsy, never properly awake. It is quite noticeable that her field of consciousness is curiously contracted and incomplete. She sees and perceives all that is going on about her, yet abnormally few associated ideas are aroused. She knows her friends and in a limited way she recognises the

scenes among which she lives, but she does not know about them in the way she used to do. To recognise her most intimate friend is a mental effort, while most of the ideas which clustered round and made their intimacy have slipped away from her mind. At length she falls asleep, but the sleep is unrestful and broken by disturbing dreams. When she wakes it is under a new phase of personality. She is no longer the person who went to sleep, but one who existed perhaps years ago. She thinks and feels as she did in that past. She usually only knows the things and recognises the persons whom she then knew. (This last statement is not invariably true. I have more than once seen the patient recognise in a partial sort of way persons whom she did not know in the life she had gone back to live. It rarely, if ever, happens that the revival is quite pure and unmixed with elements belonging to other phases of consciousness.) Occasionally, too, elements reappear derived from books or from the experience of others which have incorporated themselves with her consciousness in the past. I think that in these cases the change of consciousness has always come about in the dream. The patient has begun to dream of her past life, and then on waking has waked into that consciousness of which she has dreamed. Sometimes the disintegration of the elements of consciousness is still more complete. The consciousness into which the patient wakes contains but a few even of the elements which it possessed in the past. Thus the personality is very incomplete, the consciousness more contracted than was ever the case in health.

This obliteration of a part of the field of consciousness is probably always present to a greater or less extent in the abnormalities of consciousness which we are discussing. All such conditions have their origin in a more or less complete state of amnesia. The normal unit of consciousness has been broken up. The self has been disintegrated. Much that went to build up the vessel has been for the time lost in the shipwreck, while parts of the structure which were overlaid and hidden in the perfect and completed vessel come now again to the surface.

A case of this kind where it is possible to trace the origin of the elements of the newly-assumed personality gives one the key to those more complicated cases—found mostly in the records of continental authors though seen occasionally among ourselves—where the assumed consciousness is of so complex a nature that it is at first sight difficult to see how it has been built up out of the disintegrated consciousness of the patient. Yet this difficulty only arises when we forget the innumerable memory-images which go to build up the mental self of each one of us and the immense number which are ordinarily submerged or inhibited by the comparatively few which form the basis of our present consciousness.

It is easier from this point of view to understand those cases in which a person in an abnormal state of consciousness exhibits powers or knowledge which he did not consciously possess while in his normal condition. We have all possessed knowledge in the past which we can no longer call up at will. In the mental shipwreck it is just these forgotten fragments which get tossed up to the surface. Again, certain of our powers are, in the course of normal life, held in check by other more special powers or by knowledge more recently acquired. Children's muscular combinations are not inhibited by the knowledge of possible results or overlaid by other more special or more recently acquired combinations, so we are often astonished by the ease with which they learn to dive, swim, ride a bicycle, walk a tight rope, &c. This is also doubtless the explanation of the marvellous physical feats occasionally performed by somnambulists. The abyss below the precipice does not exist for them for they have no mental picture of it.

Exactly the same thing applies to mental powers. The phenomena of dream memory may be noticed in this relation. The dream state is a state of partial consciousness, and by reason of the absence of some elements of the normal self certain of the remaining ones may stand out with unusual prominence. It occasionally happens that in a dream we recollect a matter which in our waking moments has evaded our utmost efforts to recall it. Sometimes a piece of information which the dreamer in his waking moments has forgotten that he has ever possessed but which is now of the greatest importance to him drifts up to the surface of the dream consciousness. He wakes possessing information which so far as he can tell has come to him for the first time in his sleep. It is small wonder if in a less critical age such occurrences have been attributed to supernatural intervention.

This explanation, however, does not cover all cases of additional powers and knowledge exhibited by the subjects of these abnormalities of consciousness. Such persons occasionally exhibit powers which they have never at any stage of their existence consciously possessed. A servant girl was in the habit while in a state of abnormal consciousness of reciting long passages from Greek and Hebrew authors which she had heard her master read but of which in her normal state she could not repeat a word. A girl who in her normal state could play but little on the piano, while in a state of abnormal consciousness played brilliantly and without her notes a long and difficult passage which in her normal state she could not play at all without her notes and only very imperfectly with them. Such cases as these are not a mere revival of powers which the subject possessed in the past. The power has never been possessed by the normal, or what I will call the principal, personality. By the side of this principal personality there have existed the elements of another consciousness, submerged beneath the normal conscious self. But now there has been a partial break-up of the normal self which has allowed the rising to the surface of this secondary self with its powers and its knowledge whose existence has been absolutely unsuspected by the principal personality. So we get an alternation of personalities, the principal normal self and the secondary self each with their own capacities. Powers possessed by the one state and knowledge acquired by it are very often not at the service of the other self and are not even suspected by it. The same thing occurs to a limited extent in the phenomena of distracted attention even in healthy persons and still more markedly in hysterical and hypnotic conditions. The secondary consciousness may see, hear, feel, and even say and do things that are not participated in by the principal consciousness which is engaged elsewhere. Automatic writing as seen in hysterical and hypnotic subjects belongs to the same class of phenomena. In these cases the anæsthetic right hand will, if a pen be put into it and the hand be screened from the patient's sight, write answers to questions though owing to the anæsthesia the subject is quite unconscious that the hand is even holding a pen and much more what it is writing. A secondary personality, which under normal circumstances is subconscious, may be said to speak through the anæsthetic limb. This secondary personality is usually completely overshadowed by the principal personality and it is by this means alone that unity and clearness of thought can be obtained. In certain abnormal states, as hysterical and hypnotic states, states produced by auto-suggestion such as are seen in the trances of mediums, the principal personality is dethroned and with it goes intellectual unity, while instead we get a usually highly contracted field of consciousness with, it may be, certain powers curiously augmented.

To maintain the existence of this usually subconscious personality we do not need to call any supernatural ideas to our aid. We merely want to grasp the fact that our mental self is made up of innumerable elements, and that only a very small proportion of these are contained in the field of our normal consciousness. The great majority, like the stones which form some great building, are normally hidden from view, concealed and overlaid in the walls and foundations. So it is with the structure which is the normal self of each one of us. Yet those same stones might form either a totally different building or a heap of ruins. The consciousness of the hysteric is like a building whose walls are in a state of unstable equilibrium, always threatening to collapse, and when this does happen the elements immediately pile themselves together into a different form.

The study of hysteria and allied states brings us to the conclusion that the key to the understanding of the whole situation is the recognition of the state of partial amnesia. The anæsthesias, the paralyses, the losses and perversions of special senses can be understood only as temporary blanks in the normal consciousness, as temporary fallings away of stones from the walls of the building. It must be remembered that we have evidence that the anæsthetic limb does feel, the blind eye does see, the deaf ear hears, but the results of that seeing and hearing do not form part of the principal normal consciousness. The emotional and moral changes of the hysteric, are, I think, to be understood in the same way. The motives and ideas which in the normal state directed conduct are swallowed up in the break up of consciousness. Other motives are uncovered—usually less complicated, less disciplined, and more

coloured by the sense of self. The exact nature of the mental and emotional changes will depend upon the character of the new consciousness, and it is, I think, a grave mistake to let the diagnosis depend upon the exact nature of these changes and so to cut off cases of hysteria where the moral change is of a certain nature from closely allied cases where the moral change is a different one. So we might trace out all the features of the hysteric. It is a state of deprivation, of loss of powers, ideas, guiding principles, even though occasionally some one power or idea towers up out of all proportion to its development in the normal personality.

The phenomena of sleep and dreaming and of the hypnagogic or half-awakened state furnish us with examples of the genesis of double consciousness in the healthy life. Sleep is the resting time of consciousness. The lower centres are active, but those particular combinations of higher centres with which consciousness is conjoined are quiescent. In quiet dreamless sleep this rest of consciousness is complete and I believe sleep to be always dreamless in states of perfect health—of physical and mental equilibrium. Often, however, some slight irritant, either internal as a stimulus from stomach or intestine, or external as a noise, a light, or an unaccustomed position, breaks up this perfect equilibrium, rouses some of the higher centres, and with them an incomplete consciousness. There is a partial awaking of the psychic life but it is always incomplete. The dream consciousness is never co-extensive with the fully roused consciousness of normal active life and sometimes differs very widely from it.

We often notice in dreams a certain vagueness and confusion in our ideas of personality arising from this imperfect consciousness. We do something in our dream which in real life would cover us with shame and confusion, yet we merely wonder at it as we should in our waking moments at the deed of someone with whom we had no concern. The lack of power of forming a judgment and the want of resource of dreamers which have been noticed by everyone are in the same way due to the imperfect consciousness. Again, most of us have in dreams committed deeds from which we should not only shrink in waking life, but the motives leading to such deeds would be so completely inhibited by other ideas and motives that they would not present themselves to us as temptations. Our full consciousness is not awake, our ordinary motives and ideas are many of them inactive, and so in our dreams we are different persons, actuated by other motives, and driven to other deeds. Truly has dreaming been called a temporary insanity.

The hypnagogic or half-awakened state is only seen in health when the subject is suddenly awakened from a deep sleep before he has been sufficiently rested. In hysterical and post-epileptic conditions a more developed half-awakened state is seen, lasting for a longer time. It is the transition between sleep and waking, and so is marked by an impaired and enfeebled consciousness. The half-awakened person sees and perceives everything, but he is wanting in associated ideas. He cannot correlate facts, draw conclusions, or form judgments. He is therefore in a peculiarly suggestible state—open to the conclusions and judgments of others. He can be made to believe impossible statements and to accept opposed conclusions. The ideas usually associated with these statements and conclusions are inactive; therefore the evidence which would naturally occur to the mind and prevent their acceptance is absent. As is usual in states of great suggestibility the ideas and statements most easily accepted are those of a sorrowful and depressing nature.

The close relation between the hypnagogic state and hysterical and hypnotic conditions is easily seen. Not only do we in hysteria and allied conditions find the hypnagogic state to be unduly developed and prolonged, but the changes of consciousness seen in hysteria approach those of the hypnagogic state. Both are states in which consciousness is unusually feebly developed. In each of them in consequence the thoughts, feelings, memory-images that existed in the normal mind are many of them absent, while those that exist are less under the control of voluntary attention. In hysteria this may go on to the complete disintegration of the normal consciousness and to the formation, as we have described, of abnormal states of consciousness and so of personality.

There is another abnormality of consciousness closely allied to sleep which occurs, I believe, frequently in cases of hysteria and mental exhaustion, but which is not often noticed as it is mistaken for a faint or for an attack of *petit mal*. This is a temporary but complete loss of consciousness. It occurs usually without any warning and even while the patient is reading, talking, or walking. The attack may last from a few seconds, when it may pass unnoticed by companions, to many minutes. The loss of consciousness is absolutely complete; there is no possibility of rousing the attention until the attack has passed off, so it is impossible to wake the patient from an attack. At the same time the lower centres are more active than in normal sleep, as shown by the fact that an easy sitting position is often maintained. I have several times noticed that the patient may wake from one of these attacks in a condition of altered personality, as we noticed was the case with ordinary sleep.

I do not think that one is justified in labeling these attacks as *petit mal*. In my experience they occur in subjects in whom there is neither any personal nor any family history of epilepsy. They are never accompanied by any of the ordinary stigmata of epilepsy, as the cry, the emission of urine, or the biting of the tongue. They occur only in conditions of mental exhaustion and they totally disappear on the recovery of the normal mental health. They are not ordinary faints, as there is no change in the heart's action or circulatory disturbance of any kind. They are, I consider, merely the expression of an exhausted consciousness most nearly allied to the snatches of momentary sleep, "dog sleeps," of which we have all had experience when deprived of sleep for an unusually long time. Only in this condition as the exhaustion is abnormal so the lapses of consciousness are abnormal in their depth, and in them the threatened mental disintegration may be completed.

All the conditions touched upon above are characterised by a peculiar susceptibility to suggestion. Dreams are usually suggested by some external circumstance. Heavy bedclothes may produce a dream of fetters, a noise may suggest a battle or a storm. This suggestibility is the expression of the contracted or exhausted consciousness. Voluntary attention has failed, associated ideas are absent, so the ordinary judgments and correlations of ideas do not take place. This, of course, is normal in sleep and is only pathological when it becomes chronic. All these conditions seem to fit into one clinical picture beginning with the natural exhaustion of sleep and leading on to the pathological exhaustion of the post-epileptic, hysterical, and allied states.

The question now naturally arises as to whether there is any pathological condition common to these various states. In hysteria, I think, we invariably find an exceptionally feeble tone of the vaso-motor system. The blood-vessels react very slowly to any stimulus. The pupils are widely dilated. Red patches on the skin produced by pressure are very slow to disappear. The amount of urine passed may be at one time very much above, at another very much below, the average. The same phenomena are seen more markedly in post-epileptic conditions. This points to some irregular distribution of vaso-motor tone.

It seems probable that this irregularity in the calibre of the blood-vessels also affects the vessels of the brain. We now know that the blood-vessels of the brain possess vaso-motor nerves and such a supposition is by no means invalidated by the recent work of Dr. Leonard Hill since the total fluid contents of the brain need not vary. A study of the cerebral circulation in sleep, dreaming, and the half-awakened state gives weight to the view that in these states also there may be some irregular cerebral anæmia. There is a good deal of difference of opinion as to the state of the cerebral circulation during sleep. Some authorities consider that there may be some partial congestion. Mosso, on the other hand, believes that there is a state of anæmia at least of certain portions of the brain, the vessels dilating in dreaming or on partial awakening. In the hypnagogic state, the passage between sleeping and waking, the tone of the vessels must alter from that normal to sleep to that of waking. It is curious to note that anything calculated to restore quickly the vascular tone, as cold applied to the face and head, causes the hypnagogic state rapidly to disappear. It is only suggested that this may be a single pathological condition underlying these various states of exhaustion. We must suppose there are many others.

I have, of course, made no attempt to explain these strange conditions of changed and multiplied personality. I have merely tried to bring them, for purposes of study, into line with other simpler and more easily investigated states

and to show their relation to the phenomena of dreaming and sleep-waking. From these simpler states it is so much easier to pick out the thread which unites the whole.

Newcastle-upon-Tyne.

A NOTE ON

# THROMBOSIS IN THE VEINS OF THE PELVIS AND LOWER EXTREMITIES AFTER OPERATIONS.

BY K. G. LENNANDER, HON. F.R.C.S. ENG.,
PROFESSOR OF SURGERY IN THE UNIVERSITY OF UPSALA.

*(Translated from the Swedish by I. Walker Hall, M.B. Vict., Senior Demonstrator of Physiology, Owens College, Manchester.)*

SOME remarks of mine upon this subject appeared in the Upsala *Lakare Förenings Förhandlingar* of January, 1899, and in the *Centralblatt für Chirurgie*, 1899. The results obtained during 18 months following July, 1897, led me to suggest that after every herniotomy or abdominal operation the patient's bed should be raised at its lower end some 10 to 50 centimetres (from 4 to 19 inches) in order mechanically to assist the venous blood flowing from the lower extremities towards the heart, and so preventing thrombosis. This could be best accomplished by placing square pieces of wood under the feet. By such means the change in the position of the body caused the blood to flow along a plane inclined towards the inferior vena cava, and if the shoulders were not raised equally so towards the right auricle. Such a raising of the bed must therefore also make the flow of the blood from the veins in the true pelvis and from the exterior genitals more rapid than in the horizontal position. When the blood-stream has reached the inferior vena cava it will certainly be impelled towards the heart by the negative pressure in the thorax at every inspiration. Since January, 1899, this procedure has been adopted up to date in my practice and no case of thrombosis in the pelvic or lower extremity veins has occurred during three years. As a rule the foot of the bed is raised from 15 to 30 centimetres (from six to 12 inches) but during convalescence it can be lowered to from 10 to 15 centimetres (from four to six inches), and the latter height ought to be maintained in many cases even when the patient has returned home. In cases of cardiac lesions or cardiac debility and in those of local venous changes the elevation is even more important. The elevation should then be from 25 to 40 or 50 centimetres (from 10 to 15 or 19 inches) for the first few days. Cardiac tonics, digitalis, camphor, strychnine, and subcutaneous or intravenous saline injections should be administered before and after narcosis in all cases of cardiac debility. With famished and emaciated patients subcutaneous injections may be given of from 500 to 1000 cubic centimetres (from 17 to 35 ounces) of solution of grape sugar (strength from 5 to 10 per cent.), as well as injections of olive oil, from 50 to 200 cubic centimetres (from one and a half to seven ounces) in 24 hours with from 2 to 3 per cent. of alcohol. The injections can be given in such a way that from 5 to 10 per cent. dextrose and from 2 to 3 per cent. alcohol may be added to normal saline solutions, but 10 per cent. dextrose solution causes pain during and after injection and shows a little sugar in the urine. It is equally important to suit the narcosis as far as possible to the patient's condition (viz., morphia, $CHCl_3$, ether combined with local anæsthesia, &c.) in order to maintain the circulation and in this way prevent thrombosis.

According to Ziegler thrombosis is caused (1) by slowing of the blood-stream, and (2) by local vascular changes. In laparotomy and hernia patients there are several conditions leading to slowing of the blood-stream and more particularly in the veins of the lower extremities. Many have weak hearts from long illness and are feeble almost to starvation point. Hence after the anæsthetic one often fears fatty degeneration of the cardiac muscle. Furthermore the circulation in the calf of the leg in weak patients may be almost stagnant from the continued supine position, and if there are any varicose veins (especially saccular, where the sacs communicate with the main vessel by narrow orifices) the blood readily stagnates. Laparotomy patients are also frequently troubled by more or less "meteorism" and each increased tension of the bowels increases the intra-abdominal pressure, diminishes the extent of inspiration, lowers the negative intra-thoracic pressure, and so lessens all the forces which promote the venous flow from the iliac veins to the right auricle.

Local vascular changes, phlebitis, fatty degeneration of the endothelium, &c., may be primarily local, or secondary to infective or autotoxic conditions. Primary vascular changes are always found in patients with varices and in those who have recently suffered from blood clotting. I believe that nothing predisposes more to thrombosis after operations than previous coagulation in the larger veins of the lower extremity or pelvis. Experimental and microscopical evidence points to the probability that a thrombus in circulating blood commences from deposits of the blood plates ("Blutplaettchen") on the vessel walls, between which a small or large number of leucocytes are found. This gathering together of small granules is called "conglutination" by Eberth. If the blood-stream is sufficiently slow coagulation may ensue from the fibrin ferment which is set free from the white blood corpuscles during the act of conglutination. As the result of this united conglutination and coagulation the vessel lumen is rapidly occluded. Distally the coagulation extends in the vessels to the nearest large branch, where the blood-stream is again free. Proximally the blood will also be clotted if the local circulation is sufficiently slow. Hence, we may find a thrombus extending very quickly from the foot all the way upwards through the crural to the iliac veins in a patient who at first only complains of pain in the calf.

In flowing blood fibrin ferment is very quickly destroyed, hence a rapid or normal circulation ensures such destruction. If we then wish to prevent the formation or spreading of a thrombus it is necessary to combat all causes of local stasis. For the pelvic and lower extremity veins the raising of the lower end of a patient's bed should be of considerable mechanical assistance in promoting the flow of blood towards the inferior vena cava and right auricle. The value of this aid may be increased and the patient made more comfortable by frequently altering his position in the bed, and lightly rubbing the feet and legs, provided that he has not already a thrombus. If any varices exist on the distal side of the operation wound in a lower extremity the part should be bandaged from the foot to such a point, the leg should be elevated, or, better, the bed should be raised. This procedure exerts a very much more noticeable influence upon the circulation. By its use I believe we may largely prevent thrombosis following surgical operations, parturition, and those diseases which are accompanied by intense anæmia and auto-intoxication, in which a tendency towards the complication of thrombosis exists.

I consider myself also entitled to ask physicians to use this suggestion of "bed elevation" for preventing thrombosis. Anæmic patients often rest and sleep better after such an arrangement of the bed. Patients with medium-sized varices on their feet or legs if their limbs have not been bandaged during the day often feel restless and tired with aching in their legs at bedtime and are consequently unable to sleep for several hours. For such persons an elevation of from eight or 12 to 15 centimetres (from three or four and a half to six inches) should be employed at night. After a few nights' experience of the position in question these patients will sleep better and the unpleasant sensations in their limbs will entirely disappear.

Upsala.

THE MEDICAL DEPARTMENT OF MCGILL UNIVERSITY.—Some $60,000 (£12,000) is now being expended in new class-rooms which are to be ready for the opening of the regular session in October. When the call to arms came for volunteers to serve the Empire in the South African campaign McGill University sent many of her students and not a few from the medical department. Two of these have met a soldier's death and now fill honoured soldiers' graves in that far south land—Mr. E. P. O'Reily, son of Dr. O'Reily of Hamilton, Ontario, and Lieutenant Border, the only son of Canada's Minister of Militia, himself an M.D. McGill can be consoled in her loss by the thought that her two sons have died fighting for Queen and Empire.

# HEATSTROKE IN INDIA: AN EXAMINATION OF SOME STATISTICS RELATING THERETO.

BY W. J. BUCHANAN, B.A., M.B., D.P.H. DUB.,
MAJOR, I.M.S.; OFFICIAL STATISTICAL OFFICER TO THE GOVERNMENT OF INDIA IN THE MEDICAL DEPARTMENT.

THE purpose of this paper is not to discuss the whole question of the occurrence of heatstroke in India but rather to find out how far certain statements made in Dr. Sambon's article on "Sunstroke as an Infectious Disease" are borne out by an examination of the medical statistical records of the European army in India—statements which have proved so "infectious" that they have been repeated with but little discrimination in several recent publications dealing with the disease. The first criticism suggested by a perusal of Dr. Sambon's article is that one is somewhat at a loss to find out how from available records Dr. Sambon was able to discriminate between cases of syncope produced by heat and the more severe form of heatstroke to which he wishes to give the name "siriasis," a term which savours more of atmospheric influences than Dr. Sambon should care to countenance. It is easy to say that cases which do not seem to agree with one's theory "are only cases of syncope." In order to avoid this error in the following tables I have taken only fatal cases of heatstroke. Dr. Sambon says that in syncopal cases "immediate recovery is the rule," therefore we are safe in concluding that the fatal cases recorded in the following tables are examples of what he would call "siriasis," but which we prefer to call by the expressive and simpler name of "heatstroke." Dr. Sambon has fallen foul of the expression "heat-apoplexy," which, however, is the term sanctioned by the Royal College of Physicians of London in their "Nomenclature of Diseases," the use of which is officially enjoined for all medical statistical returns in India. Dr. Sambon may be assured that medical men in India do not confuse the cases they call heat-apoplexy with cerebral hæmorrhage or other such disease.

The statements of Dr. Sambon which will be here examined are as follows:—1. New arrivals are more liable to be attacked than natives or old residents ..... acclimatisation reduces the susceptibility to siriasis. 2. Siriasis is not always found in the warmest regions. 3. Siriasis prevails only in the "lowest regions," in "coast districts," or in the valleys of great rivers. 4. Its altitudinal range is even more restricted than that of yellow fever—this range is put down by Manson (p. 206) and by Allchin ("Manual of Medicine," vol. i., p. 13) as 600 feet. 5. It is prevalent in Lower Burma.

Taking the first statement we admit at once that Europeans newly arrived in India are more liable to be attacked by heatstroke than the natives of the country. It would be strange if it were otherwise; as Manson writes of the natives of tropical countries, "Their physiological activities are attuned by custom and habit to the conditions to which they were born." The following table shows to what an extent this is true.

TABLE I.—*Number of Admissions and Deaths from Heatstroke in Europeans in India and Natives.*

| Year. | European army, average strength 68,000. | | Native army, average strength 124,000. | | Native prisoners, average strength 110,000. | |
|---|---|---|---|---|---|---|
| | Admissions. | Deaths. | Admissions. | Deaths. | Admissions. | Deaths. |
| 1898 ... | 369 | 79 | 31 | 11 | 122 | 40 |
| 1897 ... | 257 | 51 | 32 | 11 | 103 | 52 |
| 1896 ... | 268 | 49 | 46 | 26 | 110 | 41 |
| 1895 ... | 143 | 60 | 34 | 12 | 71 | 37 |
| Total | 1037 | 239 | 143 | 60 | 406 | 170 |
| — | Deaths per mille = 3·5. | | Deaths per mille = 0·48. | | Deaths per mille = 1·5. | |

We now come to a consideration of the statement about new arrivals contrasted with old residents (Tables II., III., and IV.).

The above tables show that Dr. Sambon's statement contains only part of the truth, and baldly stated as above it is certainly misleading. The tables give the ratio per mille mortality of the disease for eight years, they cannot be grouped in one table owing to an alteration in the headings. In both tables, however, we find that new arrivals do suffer more than others, but this is only part of the truth, for it is shown that this liability decreases for a few years following the first, and then more or less steadily increases in proportion to the length of residence in India.

There is no need here to invoke the analogy of other diseases, the explanation is simple enough. It will be admitted by everyone who has lived any length of time in the tropics that recklessness and carelessness are characteristic of the new arrival in any hot country. Again to quote Manson: "The new arrival in the tropics does not think much of exposing himself to the sun, the rain, and the wind, the old resident is very chary of going out without his sun-hat and his white umbrella. ..... The new-comer may look upon these precautions as signs of effeminacy. They are not so. Experience has told the old resident that neglect means an attack of fever. ..... The new-comer sits up late, eats, drinks, and smokes as in Europe; the old resident goes to bed betimes and eats, drinks, and smokes in moderation. ..... To a great extent acclimatisation means experience, education, an intelligent adaptation of habits." These remarks apply with much force to the new-comer in his relation to exposure to the sun or great heat, and this carelessness is to a large extent sufficient to account for the greater liability of new-comers to attacks produced by the sun or heat. During the next few years the young man grows wiser, there is no acclimatisation but there is experience; nevertheless, the sun does not spare him altogether, and as he grows older, in spite of precautions, he seems to become more and more liable to the effects of heat till his percentage liability becomes at least equal to that of the first years of his inexperience. This, at least, the above tables seem to indicate, but bearing in mind the fact that the number of soldiers of the British army in India at the higher ages is considerably less than at the younger ages I do not put the case stronger than this. The per mille ratios quoted would bear a stronger statement than this, but ratios dealing with large numbers cannot with complete accuracy be compared with ratios based on small numbers, though to avoid this fallacy I have taken figures for eight years. Therefore, instead of Dr. Sambon's statement quoted above, these tables show that new-comers and old residents are the most liable to the effects of great and prolonged heat, whilst Europeans are at their best in resisting these influences in the intermediate years of their residence in India. It may also be added that M. Brault in his newly published volume, "Maladies des Pays Chauds," thinks the early years the least dangerous; he writes: "Sans doute les deux premiers étés passés sous les climats chauds sont les moins pénibles." M. Brault mentions, but does not accept, the "infectious" theory.

Dr. Sambon's next statement to be considered is that siriasis is "not always to be found in the warmest regions." Always remembering the great importance of the predisposing causes in the production of heatstroke I am inclined to challenge Dr. Sambon's statement as regards the warmest regions, although it is not clear what he means by the expression "warmest." Most decidedly it can be shown that where the heat is the fiercest and the most continuous it is there that we find heatstroke most prevalent and most fatal.[1]

The following table (Table V.) gives the death-ratios from heat-stroke in the 12 geographical groups into which India is divided for the purposes of medical statistics. I purposely chose to consider fatal cases only and therefore, as said above, presumably cases of what Dr. Sambon would call "siriasis."

TABLE V.—*Heatstroke in Relation to Geographical Groups in India. Death-rates for Four Years per 1000 of Strength (European Troops).*

| Year. | I. Burma Coast and Bay Islands. | II.* Burma Inland. | IV. Bengal and Orissa. | V. Gangetic Plain and Chutia Nagpur. | VI. Upper Sub-Himalaya. | VII. North-west Frontier, Indus Valley, and North-west Rajputana. |

* Column III. is omitted as there are no European troops in Assam.
† Averages calculated on actual cases and annual strengths.

Anyone who has lived in India will admit that for downright fierceness of the summer heat night and day no part of India is less tolerable than the North-west Frontier, the Punjab, and Sindh, and here it is that, as the above tables show, there is the greatest mortality from heatstroke. Those who have lived in Attock, Nowshera, Hyderabad (Sindh), or Peshawur in the hot weather will bear witness to the fierceness of the heat, which lasts from May till October, scarcely interrupted by the onset of the monsoon in the end of June. Next for high mortality comes the group which comprises South-east Rajputana, Gujerat, and Central India, closely followed by the upper sub-Himalayan group and then that of the Gangetic Plains. When it is remembered that these groups contain the following stations it is scarcely necessary to say more about the heat—viz., Lahore, Sialkot, Amritzur, Allahabad, Muttra, Lucknow, Cawnpur, Benares, Deesa, Ahmedabad, Jhansi, Indore, and Agra. Next on the mortality list we find Bengal and Orissa, with a distinctly lower rate per mille. The heat in Bengal and Orissa is certainly trying, but it is broken by the rains early in June; the fierce heat is not so continuous or so prolonged, the nights are somewhat cooler, and we find, consequently, a lower death-rate from this affection. Next to Bengal and Orissa we find Southern India with the following stations—Madras, St. Thomas's Mount, and Pallavarum, all close to the sea-coast, and Bellary (1483 feet) and Bangalore, 3021 feet above sea-level. Still lower on the list we find the high land known as the Deccan, with most of its stations over 1000 feet high—viz., Kirkee, 1837 feet; Poona, 1909; Satara, 2185; Belgaum, 2473; Secunderabad, 1752; Jubbalpur, 1306; Saugor, 1753; and Kamptee, 941 feet. Below this, again, comes the group consisting of the coast of Burma and the Bay Islands; here the mortality ratio falls to 0·40 per mille or one-sixth of that

[1] The following remark from an editorial article in the *Medical Review* of May, 1900, is worth quoting: "By diverting attention from the means by which siriasis may be to a great extent prevented in the army and by which many valuable lives may be saved the infectious theory is calculated to do a great deal of harm."

of Group I. On the Burma coast and in the Andaman Islands the heat is tempered by the sea-breezes and the rains come early and heavy. Still lower comes Inland Burma, with its damp relaxing climate. The stations on the West Coast show a still lower rate; they are Bombay, Cannamore, Calicut, and the small station of Mallapuram, close to the Shivarai Hills. The Hill stations, of course, show a still smaller rate. The above table therefore shows that heatstroke is the most fatal where the heat is fiercest and most continuous night and day. The same tables also dispose of Dr. Sambon's other statement that siriasis only prevails in "the lowest regions and coast districts." As a matter of fact, the lowest regions are the Burma coast, the Bay Islands, and the West Coast, and it is exactly here that the very lowest ratios for heatstroke are obtained.

I now come to Dr. Sambon's statement about the restricted altitudinal range of heatstroke, which the other writers have arbitrarily fixed at 600 feet. Turning again to Table V. we find that in the group which heads the list for mortality the worst two stations are Peshawur and Nowshera, with the heights above sea level of 1165 and 1100 feet respectively. In the next group we have the following stations, considerably above 600 feet—viz., Mhow, 1903; Indore, 1806; Nowgong, 770; Jhansi, 860; Nasirabad, 1461; and Neemuch, 1461 feet. In Group VI. which comes third on the list we have Attock, 891 feet; Campbellpur, 1200; Delhi, 715; Rawulpindi, 1707; and Roorkee, 884 feet. Taking as low as fourth place on the mortality list we meet the group of the Gangetic Plain with its stations under 600 feet. On the other hand, when we take the groups with the lowest elevations—viz., the coast towns of Burma, the Bay Islands, and the West Coast—we find all the towns have elevations little removed from the sea-level, and here we find the very lowest ratios for this disease. This shows the absurdity of laying down a law limiting the disease by an arbitrary level like 600 feet. In fact, the influence of height has little effect *per se* till we reach levels where elevation is combined with coolness of the atmosphere as in the hill stations, most of which are well over 5000 feet above sea-level.

It has already been shown that the incidence of fatal cases of heatstroke is greatest in those parts of India where the night and day heat is fiercest and most continuous;[2] it can also be shown that the disease is by far the most prevalent in the months when the heat is greatest. The following table (Table VI.) gives the monthly distribution of heatstroke cases in the European army of India for seven years, 1888–94.

TABLE VI.—*Monthly Distribution of Heatstroke cases in the European Army in India (for seven years).*

| Year. | January. | February. | March. | April. | May. | June. | July. |

N.B.—The annual reports of the Sanitary Commissioner only give the monthly distribution of heatstroke for the above seven years.

[2] In 1898 the "mean maximum" heat recorded was greatest in geographical groups No. VII. and No. VIII. of Table V., and in these areas the table shows the highest ratio for heatstroke (*Indian Weather Review* for 1898).

From this table it is seen that the following cases occurred month by month—January 4 cases, February 9 cases, March 27 cases, April 55 cases, May 190 cases, June 483 cases, July 314 cases, August 135 cases, September 78 cases, October 33 cases, November 6 cases, and December 11 cases. Here, again, is clearly seen the predominating influence of great heat in the incidence of this disease. The cases reach their lowest level in the coldest months and rise steadily and progressively through the hot months of April and May till they culminate in the truly fierce and extremely oppressive heat of June, in the dreaded period before the bursting of the monsoon rains, which as they spread steadily from the sea-coasts bring a refreshing coolness to all the land. In July and August, as the rains spread further inland and the temperature falls, the number of heatstroke cases gets gradually less till they reach a very low minimum in the delightful cold-weather months.

I have shown that the statistics of the British army in India show that heatstroke is most fatal and most prevalent where the heat is greatest and most oppressive and at the time of year when these influences are at their maximum. It will require much more evidence than has yet been produced to make those who have had experience of the disease in India accept a microbial or any other cause which seeks to minimise the great and predominating influence of fierce and continuous heat. While looking upon heat as the most important factor we must also bear in mind the great influence of the usually mentioned predisposing causes, as age, length of residence in the tropics, occupation, exposure, unsuitable clothing (as the tight-buttoned and belted uniform of soldiers), intemperance (perhaps especially beer-drinking), over-fatigue and overcrowding, want of ventilation, and previous illnesses.

Simla.

## POISONING BY CARBON MONOXIDE.

BY C. R. ELGOOD, M.D. LOND.

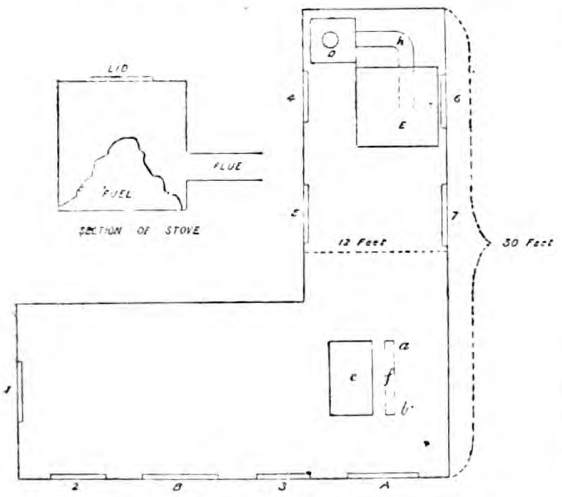
TWO women, aged 58 years and 31 years respectively, inmates of a workhouse, were at work in a large laundry provided with a stove and a good-sized hot-air chamber for drying clothes. At 6.45 in the evening another woman on entering the room found them both lying on the floor near one end of the room about four feet from a closed door leading into an airy wash-house. In both cases the bowels had acted involuntarily. The women were found lying close to each other at the foot of a form in front of a long table. The elder woman had her feet on the form on which it appeared that she had been sitting and she was covered with vomit. A nurse who was summoned found her completely stiff all over. Her arms were drawn up and her eyes were fixed and looked strange. The nurse sprinkled her with cold water and removed her from the room, when she became very sick and apparently revived. On my arrival, at 7.45 P.M., I found the patient in a bed in the infirmary. She was not breathing, there was no pulse, and no cardiac sounds could be heard with the stethoscope. There was, however, a good colour in her lips and face; so much was this the case that in spite of the fact that the woman had not been observed to breathe since she was found an hour before, artificial respiration was resorted to and was kept up for some considerable time until its obvious uselessness was apparent to all, for she never gave a gasp.

The younger woman was at the time of my visit lying in the next bed to the other; she was groaning and crying and at the same time opening her eyes widely and staring wildly round. The pupils were fully dilated and insensible to light, though they reacted in a quarter of an hour after. The breathing was noisy, rapid, and panting in character, 10 or 12 respirations following each other quickly in succession and then ceasing for a few seconds, but there was no regular cycle. No pulse could be felt at the wrist and no cardiac impulse was perceptible. There was present a rapid semiflexion and pronation of both forearms by which means the hands were brought together as if for the purpose of rubbing them. It was quite a coördinated movement and one apparently accompanying the return to consciousness. In a quarter of an hour the patient became much more conscious. She was very excited and seemed frightened and complained of pain in the head. In another

quarter of an hour a faint pulse was perceptible at the wrist. The treatment which was employed comprised friction to the limbs and cardiac region and hot coffee and enemata of brandy and milk were administered. The next day she was much better. Her pulse, however, was still small and weak and it was also irregular and intermittent. The woman was perfectly conscious and rational and gave the following account of the occurrence. As far as she remembered, she said, the first thing she noticed to be wrong was a "swimmy" feeling in the head, and she sat down on the form with her companion. After this she remembered nothing till she saw the medical officer by the side of her bed. She also stated that she had closed the windows in order that the master might not see the fire which, as subsequently transpired, the women had augmented for the purpose of cooking some potatoes which were placed on the lid of the stove. She made a rapid recovery.

The body of the elder woman was removed to the mortuary on the same evening as that on which the death had occurred. The corpse was the occasion of a good deal of uneasiness to the nurse who had to "lay it out," for, from the appearance of the body, she could not bring herself to believe that the woman was actually dead. There was no rigor mortis at 10 P.M. on that evening, but it was well marked at noon on the next day. The post-mortem examination was made about 40 hours after death, when rigor mortis had not passed off. The body was well nourished and very fat, and the face had a remarkably fresh appearance. Over the areas where hypostatic lividity is usually present a bright rose-red colouration was seen, in many cases spreading upwards in patches—e.g., on the back of the forearms and cheeks. On opening the body the blood appeared to be brighter than normal and all the organs were of a brighter colour than is usual. The intestines were still warm. The walls of the heart were thin and there was a good deal of fat around them. The cavities of the heart were empty. The valves and large vessels were healthy and there was no sign of a clot anywhere. The right lung was half the size of the left, the parietal and visceral layers of the pleura on this side being connected by old adhesions in the neighbourhood of the diaphragm and posterior thoracic wall. On section the lower and back parts of this lung were seen to be dark in colour and of firmer consistence than is usually found. The tissue, however, was everywhere crepitant and it floated in water. The left lung was of normal size and on section its colour was seen to be somewhat darker than usual, but otherwise it was healthy. The spleen was very friable and was gorged with blood. The kidneys were healthy. They exhibited the rose-red colouration more than any other organ. The other organs were all normal. The blood was everywhere fluid and no clot was seen at all.

The room in which the accident happened was quite 14 feet in height. It was of the shape of a reversed letter L, each limb measuring about 30 feet by 12 feet, and there was a stove for heating the drying apparatus in a recess in a corner below the level of the floor. On entering the room on the same evening the blue flames of carbonic oxide could be seen issuing from between the lid and the top of the stove. The air was very hot and oppressive, but was not unbearable for a time. The plan appended, which is copied from one made at the time, may help to explain the shape of the room and the position of the two women. On looking into the stove (over which there was an opening in the roof about a foot square) when it was empty it was seen that the exit pipe was placed rather nearer the bottom than the top, so that there was plenty of room to pile up fuel above its level, thus blocking up the flue and sending the fumes into the room instead of up the pipe. As it transpired from the evidence which was given at the inquest that a big fire had been made up it was concluded that this was the cause of the accident.



A, Door leading to wash-house. B, Door leading to quadrangle. 1, 2, 3 Casement windows, four feet from ground, all closed but opening easily. 4, 5, 6, 7, Ventilating windows, six feet from ground, also closed. D, Stove. E, Drying chamber. *h*, Hot air pipe. *a*, Position of body of the elder woman. *b*, Position of body of the younger woman. *c*, Table at which the two women were sitting. *f*, Form.

The fumes given off by the smothered combustion of coke vary according to the quality of the fuel. As a general rule, one expects to find, in addition to carbonic oxide and carbonic acid, sulphurous acid, sulphuretted hydrogen, light carburetted hydrogen, and olefiant gas.[1] The four latter gases, however, are so irritating to the lungs and so perceptible to smell that they seldom or never cause poisoning by themselves, but frequently even prevent the first two gases from producing ill effects, for the obvious reason that they give warning of danger. In this case there was no smell of gas in the room when I entered it, though the flames of carbonic oxide could be seen burning in the stove, and it is certain that no warning smell was appreciated by the two women. We may, therefore, conclude that carbonic oxide or carbonic acid or both were accountable for the catastrophe. These two gases, though their separate action on the body is so diverse, seem to help one another greatly in producing fatal effects. It is known that it takes 10 per cent. of carbonic acid alone to destroy life, and 5 per cent. of carbonic oxide in the atmosphere has a similar result; but if the two are combined, as little as a half per cent. of carbonic oxide with 5 per cent. of carbonic acid is a fatal dose,[2] and from the appearances then noted after death it would seem that the carbonic oxide plays the principal part.

The classical symptoms ascribed in the text-books to charcoal vapour (which may be considered as carbonic oxide, carbonic acid, aqueous vapour, and impure air)[3] are headache, pulsation in the temples, giddiness, vertigo, nausea, vomiting, convulsions, great prostration, and cardiac weakness, drowsiness, insensibility, and coma. Judging from the two cases just related and the comparative frequency with which I have found the symptom recorded in reported cases, I think that the involuntary expulsion of fæces may be added to this list. There is no doubt, too, that the poison has a powerful action on the central nervous system. Dr. Alexander Scott[4] describes a condition of mental weakness of long standing in a case under his care as illustrating the length of time that the brain retains the poison. The periodicity not infrequently observed in the symptoms as the patient regains consciousness points, I think, in the same direction. On more than one occasion a fall of body temperature has been noticed in those poisoned by carbonic oxide.[5] Of the remaining symptoms the subjective ones of pulsation in the temples and nausea were the only ones not elicited in the cases described. An illustration, too, is afforded of the insidious nature of the poison so often noticed as evidenced by the absence of any effort to escape. In this case both the women who were affected were lying close to the door which, as old inmates, they well knew led to the wash-house and fresh air.

In this connexion we cannot resist referring to the graphic account of wholesale poisoning by carbonic oxide which occurred in the disaster at the Snaefell mine as given by Dr. A. E. Miller.[6] A rescuing party was overtaken by the gas—which it was subsequently found was caused by some smouldering timber supports—and one of their number (Dr. Le Neve Foster) kept writing a description of his sensations as long as his pencil would trace words. He wrote:

[1] Taylor and Stevenson's Principles and Practice of Medical Jurisprudence, vol. ii., p. 112.
[2] Bernard: Substances Toxiques, p. 212.
[3] Taylor and Stevenson: loc. cit., p. 104.
[4] THE LANCET, Jan. 25th, 1896, p. 217.
[5] Brit. Med. Jour., vol. ii., 1895, p. 1514.
[6] Ibid., vol. ii., 1898, p. 32.

"We all sat without moving or trying to escape. The foot of the ladder was close by, yet none of us made any effort to go to it and ascend even a single rung. We none of us tried to walk a dozen steps which would have led us to the other side of the shaft partition where we all knew there was a current of better air." The same paper alludes to the remarkably fresh and life-like appearance of the corpses as they were brought to the surface, and what is still more interesting, as it bears somewhat on the treatment, we read that as soon as a warning was given that there was foul air about there was a rush among the men for the ladders and a general climbing commenced. It was soon observed that of these men, who were really poisoned before they knew it, only the elder ones got up to the top, and nearly all those "well under 30" fell down and were recovered afterwards only when they were dead. This Dr. Miller ascribed to cardiac failure consequent on the greater exertion made by the younger men to escape, it being conjectured that the elder ones took matters more leisurely and so put less strain on their heart muscles. It appears to me that, though this explanation may not appeal to all, its important bearing upon treatment seems to lie in the consideration as to whether continued vigorous efforts at artificial respiration may not by exhausting a semi-exposed patient do more harm than good.

The symptom of convulsive rigidity which was present in the only one of these two women who was found alive is so commonly stated to be present that it calls for a little remark. These spasms have been supposed to be asphyxial in their nature. They have been mostly observed to affect the extensors of the trunk and the flexors of the limbs, for in asphyxia, as Sir T. Lauder Brunton has shown, these groups of muscles overcome their antagonists and thus opisthotonos and flexion of the limbs are produced.[7] It will be remembered that the arms of the younger woman were described by the nurse as "stiff and drawn up." Whether this be the correct interpretation of the symptom or not it is well to recollect that at least two gases are present in poisoning by coke or charcoal vapour, and it is quite possible that some of the symptoms we find may be produced by either gas acting separately.

I have only been able to find one case of poisoning by the pure gas carbonic oxide. This is recorded in an old edition of Beck's Medical Jurisprudence.[8] A man at Dublin inhaled the gas for an experiment and was nearly killed. In him the poison certainly acted promptly on the central nervous system and the heart, for total insensibility and lifelessness came on at once and lasted half an hour. On introducing oxygen gas into the lungs he recovered with convulsive agitation and quick and irregular pulsation, and for some time after recovery total blindness, sickness, and vertigo were present.

One would imagine from *à priori* reasoning that as carbonic oxide forms such a stable compound with hæmoglobin there is but little chance of setting free this combined hæmoglobin, and that the only method of treatment would be to remove some of it and inject fresh into the system. And this experience fully proves to be the case. A case is related where a man was saved by this means after being in an apparently hopeless state for 48 hours.[9] He was bled to 800 grammes, and 110 grammes of defibrinated blood were injected. The record of successes is certainly not so large as one would hope. In 1885, 23 cases were collected in which transfusion had been resorted to. Recovery had ensued in eight.[10] We are not told, however, whether the blood was defibrinated in every case, nor even whether blood was used in every instance; for I note that Halstead of New York[11] has stated that saline injections are equally serviceable in the case of animals poisoned by carbonic oxide. Although he quotes Kühne as an authority for his statement, one is at a loss to understand by what means such a proceeding would be likely to do good.

I have already alluded to the possible harm that might result from the prolonged use of artificial respiration. Alone it certainly seems to be but of little use, but with the aid of such adjuncts as the inhalation of oxygen, slapping and friction over the cardiac region, and faradaisation of the phrenics it has proved of great service. The fall of temperature has suggested the use of the hot bath, and certainly the external application of warmth and the avoidance of undue exposure of the body while artificial respiration is being carried on are things to be most carefully attended to.

It has been kindly pointed out to me by Dr. E. Casey that no allusion to this subject of carbonic oxide poisoning is complete without a reference to the growing use of so-called "water-gas" as an illuminant. True water-gas, or the gas produced by the action of steam upon carbon, consists of about equal volumes of hydrogen and carbonic oxide with small quantities of nitrogen and carbonic acid.[12] This, of course, would not be of much use for illuminating purposes. The term, however, is very loosely applied and generally includes gaseous mixtures used for illumination which are distinguished from coal gas by the large quantity of carbonic oxide they contain. The main point is that the high percentage of carbonic oxide usually entails a loss of the characteristic odour of illuminating gas and hence the great danger arising from an escape of water-gas into a bedroom during the night. Water-gas as used for illuminating is said usually to contain about 30 per cent. of carbonic oxide while ordinary coal gas contains only 7 per cent. of carbonic oxide.[13] Since the introduction of water-gas into New York the deaths from burner escapes are said to have increased tenfold and in one State of America a law has been introduced limiting the percentage of carbonic oxide to 10 per cent.[14]

## GENERAL NERVOUS SHOCK, IMMEDIATE AND REMOTE, AFTER GUNSHOT AND SHELL INJURIES IN THE SOUTH AFRICAN CAMPAIGN.

BY MORGAN I. FINUCANE, M.R.C.S. ENG., L.S.A.,
CIVIL SURGEON ATTACHED TO THE CONNAUGHT HOSPITAL, NORTH CAMP, ALDERSHOT.

THE following notes of nine cases—out of a total of over 60 cases seen during the past two and a half months—with similar symptoms affecting the nervous system sufficiently illustrate some of the results, immediate and remote, which have been noticed as occurring in soldiers invalided home from the front. It is likely that in the near future the country will be deprived of a large number of our most capable and experienced men if the cases continue to occur in such frequency.

CASE 1.—At Colenso on Dec. 15th, 1899, Corporal —— was in the firing line when a bullet struck him in the left ear, entering the external auditory canal, rupturing the membrana tympana, and lodging in the mastoid process. A Mauser bullet was extracted from behind the ear at Pietermaritzburg Hospital, it being deeply imbedded in the bone, six days later. The patient was unconscious for six hours after the injury; he vomited, and blood escaped from the ear, the nose, and the mouth. Some loss of power down the left side was experienced for a month after. The wound healed well, the patient recovering power of the left side, but he still remains deaf in the left ear, with continual noises.

*Present condition.*—The patient is a thin and pale man with an anxious, careworn expression; he is only 32 years of age but looks older. His movements are slow and laboured. His body surface is cold and there is want of general muscular tone. There is a small, almost imperceptible, scar behind the left ear, over the mastoid process. The external auditory canal is normal in appearance; the membrana tympanum is gone, but no other abnormal appearance can be detected in the middle ear. He is somewhat deaf in this ear, but nothing very marked. He complains of giddiness, languor, and inability for sustained exertion of body or mind. His memory is bad and is getting worse; he is nervous and shaky, easily upset and put out, he suffers from sleeplessness at times, and his vision is dim with constant noises and lightness of head. The muscle movements are slow and impaired and he has continuously suffered with headache since the injury and in spite of every care is steadily losing weight.

CASE 2.—At Spion Kop a private of the 2nd Battalion King's Own Royal Lancashire Regiment, aged 24 years, was wounded in the left ankle, injuring the fibula and traversing the limb, and making its exit behind the tendo-Achillis. The aperture of entry was larger than that of exit. The injury was sustained whilst reinforcing the firing line. A comrade removed his boot and sock and applied the first and final dressing. The patient made an uninterrupted recovery after one month of the local injury.

*Present condition.*—Beyond some impairment of muscle movements on the plantar surface of the foot and slight stiffness around the ankle the local symptoms around the seat of injury are *nil;* there is wasting of muscles of both legs and impaired movements. There are areas of hyperæsthesia and anæsthesia and muscle reflexes are much exaggerated in both limbs; there are tremors of muscles and night twitchings of muscles of the chest and upper extremity. The patient feels very unsteady and shaky, with noises in the head and giddiness. His memory is bad and failing. The patient suffered from nerve shock and panic at Spion Kop before being wounded owing to the alarming character of the surroundings.

CASE 3.—At Colenso on Dec. 15th a private of the 2nd Queen's Regiment was wounded in the left groin with a Mauser bullet over the kidney, traversing the abdominal cavity, causing subsequent hæmaturia and peritonitis, and travelling along the inside of the right thigh and becoming lodged on the under and inner surface of the right patella, whence the bullet was removed 14 days later. The loin wound healed in 10 days and the incised wound near the patella healed rapidly after extraction of the bullet. The injury was sustained while lying down with the right leg raised.

*Present condition.*—The patient complains of abdominal pain and pain in the legs and general weakness; he is incapable of continued exertion, bodily or mental. Formerly he was a smart soldier. The pains do not follow the course of any nerve trunks, and a general nervousness and weakness are noted of the upper as of the lower extremities. The patient is pale and thin with general vaso-motor impairment, and his circulation is sluggish. His age is 27 years.

CASE 4.—At Colenso on Dec. 15th a private of the 2nd Royal West Surrey Regiment whilst in the firing line was knocked senseless by the explosion in close proximity of a nine-inch shell. The patient was not actually hit by a portion of the shell, but by the turning up of the ground. Subsequently the patient had partial loss of power down the right side in South Africa, which afterwards got better, but since coming home on July 7th he has had another attack of unconsciousness accompanied with some loss of power more noticeable on the right side.

*Present condition.*—There is distinct loss of power on both sides of the body. The patient is very nervous and shaky, suffering from twitching and especially over the right side, giddiness, noises in the head, dimness of sight, and some deafness. The skin is cold and the muscles are soft and flabby; the reflexes are exaggerated with tremors of the hands and tongue. A general condition of neurasthenia is noted.

CASE 5.—At Spion Kop on Jan. 21st a private was in the firing line when he was shot in the left temporal bone, rupturing the tympanum and passing through the mastoid process. He was unconscious, but made a good recovery from the immediate effects.

*Present condition.*—The patient is now thin and nervous, with distinct loss of power in the upper part of the body. This is general evidence of vaso-motor impairment of the skin, muscles, and subcutaneous tissues. He has vertigo, headaches, flushing, and periods of stupidness and unconsciousness. His memory is bad and is getting worse. The patient describes his nerve break-down as due to shock and panic at Spion Kop, even before receiving his wound, as the result of heavy shell-fire and rifle-fire from the Boers, who were invisible and well under cover whilst the English troops were freely exposed. The patient is only 28 years old.

CASE 6.—At Spion Kop a private was wounded in the right thigh with a Mauser bullet. The wound occluded by a first and final dressing and the patient made a rapid recovery from the local wound.

*Present condition.*—The patient has weakness, pain, and tremors in the muscles of the back and both lower limbs. His gait is unsteady and he is incapable of sustained or arduous exertion. There is no apparent loss of power. The apertures of entry and exit have healed, showing only small scars. The body-surface is cold and there is want of muscular tone. He is in a dull, lethargic mental state.

CASE 7.—A private was wounded at Colenso on Dec. 15th in the abdomen and thigh with a Mauser bullet, escaping the abdominal cavity, since which date he has had constant lightning pains in the legs and shooting into the loins and he is now quite unable to do duty.

*Present condition.*—The patient has pain, hyperæsthesia, and tenderness over the superficial and deep nerve trunks. His movements are impaired and painful. The gait is unsteady. The scars of the bullet wounds are quite healed. There is general unsteadiness of speech with restlessness. The patient's age is 27 years.

CASE 8.—A private was wounded at Slingersfontein on Feb. 12th in eight places—the hip and back, the right leg and the left arm—the bullets traversing structures and the wounds healing rapidly, since which date he has suffered from general weakness.

*Present condition.*—The patient has general tremors of most muscles of the trunk and loss of muscle tone. The surface of the body is cold. The patient's speech is slow and hesitating and he is very nervous and shaky, and unfit for long-continued mental or bodily exertion.

CASE 9.—At Spion Kop on Jan. 24th a private was wounded in the right foot with a Mauser bullet and sprained his left ankle in falling. The bullet wound did well.

*Present condition* —The patient has loss of power and general tremors of both legs and lightning pains shooting up both legs and into the spine, especially the left leg. The patient is scarcely able to walk. There are twitchings and tremors about the face, which has an anxious and pinched appearance. He sleeps little owing to night pain. The muscles of the lower extremities are wasted and reaction of degeneration is noticed. There is some tenderness along the course of the great nerves.

*Remarks.*—The most noticeable features in our large military hospitals at present to be seen amongst South African invalids sent home for gunshot injuries are the almost total want of further surgical interference required, or any marked deformity, and the trivial nature of the entrance and exit apertures produced by the Mauser rifle bullet. In all the cases coming under my care I have had none in which the bullet-wounds were not healed, and although in many cases these were very numerous they have produced little or no deformity. The number of cases of injury from shell-wounds have been proportionately very small. The apertures of entry and exit of bullet-wounds in most cases are of a similar size and the scar is markedly small with no evidence of previous laceration or contusion of surrounding parts. The history of most of these patients immediately after the wounds is that of rapid healing by first intention with little or no suppuration; from inquiries made of patients the practice of antiseptic occlusion by first and final field dressings—whether that be on the field or in the field hospital—being responsible for the rapid healing and entirely successful results of the wounds themselves. Nearly all the cases observed had been subcutaneous flesh wounds, escaping or uninjuring bones and joints in the most marvellous way, although traversing tissues and cavities in close proximity to both. The lodgment of bullets in the soft or bony parts or in the cavities, necessitating removal, is an extremely rare occurrence, due, I take it, to the high velocity and shape of the projectile. The only cases I have seen here were lodged fragments from an exploded shell.

The clinical fact of most interest undoubtedly is the large number of cases of functional impairment of nerve sense and motor power, associated with psychical symptoms akin to nervous shock or those observed after railway accidents. These nerve symptoms do not bear any ratio to the extent or size of the wounds inflicted, but have been noted by me as being more common in injuries of the lower extremities and the head, and in cases that look originally to be not severe. The implication of nerves or their sheaths is not a marked feature and in most instances there is no local evidence of the bullet or its course having been near the track of a nerve. The effects are of sufficient importance to the military authorities and to the profession generally by reason of the necessity there is at present, and probably will be in the future, before the campaign in South Africa is concluded, of invaliding a large body of our best and most seasoned and experienced soldiers out of the service as unfitted for future service as soldiers, thus denuding our army of these experienced and gallant men. A large number of such cases have come before me, where after six months' or shorter periods of complete rest and every

care, the patient's nervous system shows no signs of recovering its former steadiness and there is nothing for it but to invalid them out of the service as permanently unfit.

Again, the prognosis in such cases is extremely unsatisfactory and no definite one can properly be given under a year, whereas the military authorities require it much earlier. The surrounding circumstances of modern gunshot wounds have apparently lost much of the seriousness recorded of these injuries in most text-books, and it would appear that the resulting nerve shock and injury to the nervous system are the most frequent sequelæ and at the same time difficult to prevent and treat, but those towards which, in my opinion, our efforts must be directed. The absence of local nerve lesion or injury producing the nerve change is significant, and the number of cases observed would not support the theory of these symptoms occurring in nervous persons only. It would be interesting to ascertain the actual numbers of men who have been invalided out of the service as the result of the South African campaign after bullet wounds and shell injuries whose permanent disability is purely shattered nerves. If possible the engagement in which the patient was wounded should be ascertained. Badly conceived projects by generals and commanding officers causing panic and disaster may then be found to be largely responsible for the development of such nervous cases quite apart from surgical injuries.

Aldershot.

**Nulla autem est alia** pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

## FRENCH HOSPITAL AND DISPENSARY.

### A CASE OF PLASTIC BRONCHITIS WITH ITS POST-MORTEM APPEARANCES.

(Under the care of Dr. A. VINTRAS.)

PLASTIC bronchitis is an exceedingly rare disease, but it has been recognised from very early times and Galen has mentioned that solid masses of fibrin may be expectorated.[1] In 1897[2] Clarke and Lister explained the real method of formation of the casts and showed that they were not due to the coagulation of blood. Up to the present time more than 100 cases have been recorded, even if allowance be made for some which were probably not instances of true plastic bronchitis. The case recorded below is almost typical of the disease. Hæmoptysis is a very frequent symptom, for it occurs in about one-third of the cases, and epistaxis has also been observed.[3] The treatment by inhalations of lime-water appears to have been suggested[4] by Kuchenmeister's observation of the solubility of diphtheritic membrane in lime-water,[5] though Dixon[6] had pointed it out long before. For the notes of the case we are indebted to Dr. Henry Dardenne, physician to the French Hospital.

The patient was a man, aged 68 years. He had been for seven years a soldier in the French army and had served all his time in Africa. Since then he had had no regular occupation. He was admitted into the French Hospital on August 18th, 1894, under the care of Dr. Vintras. He complained of cough, shortness of breath, hæmoptysis, and pains across the chest both in front and behind between the shoulder-blades. His illness began three months previously after allowing his clothes, which had been soaked through with the rain, to dry on him. He remained after this for two days in bed. Since that time he had been troubled with fits of coughing which were now and again very severe. A month previously to admission he noticed for the first time that after one of these fits his expectoration was tinged with blood, very thick, and almost gelatinous in consistence. He used to feel better for a day or two and then he would have another attack of coughing. These also became more severe. A week before admission he spat about three ounces of dark coagulated blood. He had for 12 hours a very severe pain across the chest in front, and this, together with a most distressing cough, lasted until he had expectorated some very thick and dark matter. His breathing then became much easier. He had before this always enjoyed good health. His habits had always been regular and he never drank to excess. There was nothing particular in his family history. His father died at the age of 78 years from cerebral hæmorrhage, his mother at 50 years of age from pneumonia. He remembered nothing about his grandparents. An uncle of his suffered from asthma and died from kidney disease. The patient was 5 feet 11 inches in height and was very emaciated. His weight six years before was 12 st. and on his admission it was only 10 st. His features were sharp and his complexion was sallow and pasty. His lips and ears were slightly cyanotic. His conjunctivæ were slightly jaundiced. The alæ nasi moved freely with each inspiration. The veins of the cheeks were dilated. His expression at times was very anxious and careworn. His temperature was normal. On examination his chest was found to be barrel-shaped. Its mobility was deficient. The sterno-mastoids stood in bold relief and could be seen to contract on inspiration. The vocal fremitus and resonance were normal. The chest was tympanitic in front. The right base behind was somewhat dull. On auscultation rhonchi and sonorous and sibilant râles were present over the whole chest both in front and behind. At the right base behind there was a respiratory murmur very indistinct and the vocal fremitus here was slightly impaired. The pulse was regular, full, incompressible, and beating at the rate of 100 per minute. The arteries were tortuous and indurated. The apex beat could be felt and seen in the sixth left intercostal space, half an inch outside the mamillary line. The heart-sounds could not be distinctly heard and neither the superficial nor the deep cardiac dulness could be detected owing to the emphysematous condition of the lungs. The teeth were decayed. The tongue was large and flabby, the papillæ were very prominent, and there were here and there a few superficial fissures. It was coated with a white fur except at the tip and edges. He had at times some difficulty in swallowing his solid food and this had increased within the last fortnight. He complained of no morbid sensations either before or after food. His appetite was good. His bowels were regular. The other systems appeared to be normal. On August 22nd, four days after the patient's admission, Dr. Dardenne was hastily summoned to the patient. He found him suffering from intense dyspnœa and he seemed to be on the verge of suffocation. His face was livid and covered with a cold perspiration. His eyes were bloodshot and looked as if they would come out of their sockets. The muscles of forced inspiration were acting powerfully and both hypochondriacal regions receded during inspiration. His breathing was about 60 per minute. His voice could scarcely be heard and the patient complained of pain and of a sense of pressure in the epigastrium and between the shoulder-blades. He had an incessant and harassing cough, and this would at times be relieved by the expectoration of a thick, sanguinolent fluid. Suddenly his face became quite black and he gasped for breath. His body was shaken with a severe fit of coughing. Tracheotomy appeared to be inevitable. However, with considerable effort he succeeded in expectorating a dark mass of the size of a cherry-stone, and this was followed by about two ounces of dark, semi-clotted blood. He felt instantly relieved and sank back exhausted. On floating the little black mass into water it turned out to be a perfect cast of a middle-sized bronchus with its ramifications. It was yellowish in colour and three and a half inches in length. For the next two or three days he spat some muco-purulent fluid and felt much easier. The respiratory murmurs were more distinct at the right base behind. The pains had disappeared and he expectorated no casts, only some dark blood and mucus. On the 26th he had another attack of dyspnœa, not so severe as the previous one, but he complained of the same severe pain in the epigastrium and between the shoulder-blades. On this occasion he expectorated about 15 casts. They were this time very soft and friable and much whiter than the first one. Peculiar adventitious sounds were to be

heard before he had the last fit. Some authors have called these "bruits du drapeau." For a week after this he complained of no pain but of a feeling of lassitude and expectorated a sanguinolent fluid. On Sept. 2nd the patient had another attack and died suddenly. Artificial respiration and tracheotomy were of no avail.

*Necropsy.*—On post-mortem examination 15 hours after death rigidity and lividity were well marked. Both lungs were adherent and extremely emphysematous. The thoracic viscera were removed *en masse* together with the tongue, the trachea, and the œsophagus. On slitting the latter open a soft, rapidly growing epithelioma was detected about half an inch above the tracheal bifurcation. It extended for an inch above and below this and was firmly adherent to the trachea which was also compressed by the growth and at this point could hardly admit a small goose quill. A cast was found projecting from the right bronchus into the trachea and blocking the already strictured lumen of the latter. It measured two inches in length and was milk-white in colour. The mucous membrane of the right bronchus was intensely congested. Only one small cast was also detected in one of the tubes of the right middle lobe. Both lungs were crepitant but intensely congested. There was no trace of tubercles anywhere. The heart was enlarged and weighed 15 ounces. The valves were healthy and competent. The right ventricle contained some coagulated blood; the left was empty. The brain and spinal cord were congested and so were the liver and kidneys.

*Nature of the casts.*—When first expectorated they were either by themselves or rolled in the form of a little ball coated with thick muco-sanguinolent fluid. In colour they were pale yellow. The ends of the casts were bulbous, thus showing that they had extended into the infundibula, and the large cast could be inflated. On its surface there were some bulgings, this most likely caused by the more or less rapid deposit of fibrin. In consistence they were tolerably compact and to some extent elastic. On cross section concentric layers of a lamellar fibrillated structure were seen, and between the layers there were inclosed leucocytes, pus corpuscles, and some cylindrical epithelium—but very few blood corpuscles. Crystals of Charcot were not present. The casts were insoluble in water, but were soluble in lime water to a great extent. The casts, in my opinion, were made up of fibrin and not of mucus or of a coagulation necrosis of the bronchial epithelium, as was once thought. The alveolar vessels were congested. The treatment consisted in the intervals in the patient taking every three or four hours inhalations of lime water and internally a mixture of iodide of potassium and some expectorant. During the fits nitrite of amyl was tried but with no benefit. A mixture of A.C.E. and apomorphine subcutaneously seemed to shorten the attack.

*Remarks by* Dr. DARDENNE.—Plastic or fibrinous bronchitis is a very rare disease, and there are very few cases reported where its post-mortem appearances have been noted. In the above case I had every possible opportunity to observe its clinical characters, the deceased being at the time an inmate of the French Hospital. I have since met with another case in private practice.

## ROYAL NAVAL HOSPITAL, GREAT YARMOUTH.

### A CASE OF HYDATID DISEASE OF THE LIVER DISCOVERED BY THE PRESENCE OF DAUGHTER CYSTS IN THE MOTIONS.

(Under the care of Surgeon F. H. A. CLAYTON, R.N.)

THE cases are few in number in which an hydatid of the liver has discharged its contents through the common bile duct and still rarer are the cases in which recovery has followed, for in most of these cases, though some part of the cyst has escaped into the bowel, the remainder has required an operation for its removal or has been found post mortem. The comparative infrequency of hydatids in this country and the peculiar features in this case render it well worth recording.

The patient was a strong and healthy-looking man, aged 38 years, an attendant at the Royal Naval Hospital, Great Yarmouth. The only point of any significance in his previous history was that 12 or 14 years ago he was engaged in looking after some greyhounds. His illness commenced about Dec. 27th, 1899, when he was put upon the sick list, complaining of headache and diarrhœa, but with no chill or rigor. His temperature remained between 102° and 103° F. for four or five days, with a morning fall of about a degree, and showed some tendency to steadily rise. With this he was passing three or four pea-soupy motions daily; his tongue was furred, dry, and typhoid-like, and his liver was somewhat enlarged, but beyond slight pain and tenderness in the right hypochondriac region he complained of little. With liquid diet and the administration of an intestinal antiseptic all symptoms disappeared, although there was for some time a slight nocturnal rise of temperature. He returned to duty on Jan. 16th, 1900, three weeks after admission. On March 4th he suffered from considerable colicky pain about the epigastrium, shooting round to the right loin, but was free from this when seen on the next morning, although he was somewhat jaundiced. Jaundice increased during the day and the liver was found considerably, though uniformly, enlarged. Under treatment symptoms rapidly disappeared, and as he was anxious to return to work he was discharged to light duty on the 13th. On the 16th he relieved the gate-porter on a cold day without wearing a great-coat, although warned to avoid chill, and almost at once began to shiver and could not get warm. He was seen next day and complained of the shivering and of the same pain as before, but less severe, and also of anorexia and general malaise. His temperature was again 102° but fell to normal during the next three days, and the jaundice, which reappeared the day following admission to the sick list, was likewise evanescent. This time he was kept on the sick list for several days after apparent recovery and was first allowed to go home on the 30th. Here he partook of some cake and a glass of beer, and afterwards during the entire night suffered far more severely than before from a return of the same colicky pain, and on coming in next morning he was described as being bent like an old man. When seen this had again passed off, but, as before, his temperature was raised and a return of the jaundice soon made itself evident.

On searching the motion passed on this day for gallstones about a dozen cyst-like bodies were found which varied in size from a pea to a large bean. Some of them (apparently the larger ones) were ruptured, and all contained turbid fluid, and were white and membranous looking. A microscopical examination of the contents of one revealed numerous scolices with their rings of hooklets and several stray hooklets. These bodies were found on various occasions afterwards, usually smaller and unruptured, except after a similar attack on April 19th. With them much slimy gelatinous matter and fragments of white membranous material, apparently portions of cyst wall, had also been passed, and at times some had been bile-stained. Latterly few cysts had been seen and only the fragments of the wall. These were always of much the same size—that of a small pea. The liver enlargement had at this time (March 31st) increased but was still uniform; there was slight epigastric tenderness but nowhere any suggestion of a thrill or localised enlargement. His appetite remained poor and he displayed great susceptibility to draughts though he complained of no definite chilliness. He also had slight occasional epigastric pain and tenderness but otherwise remained well until April 19th, two days after being allowed out in the grounds, when he had another severe attack of pain all the afternoon. On this occasion he was seen to be pallid, collapsed, and covered with clammy sweat. An injection of morphia (one-sixth of a grain) almost at once relieved him. This attack was previously followed by transient jaundice. He passed a motion which was clay-coloured containing several more ruptured large cysts. His urine on one or two occasions after the attacks had been very thick with urates and contained much bile, otherwise it presented no abnormality, and there was no sign of respiratory, circulatory, or nervous involvement. After this attack the patient steadily improved and was discharged to duty on May 2nd. Although his liver is still much enlarged and he continues to pass fragments he is gaining flesh and remains well, and up to the present time (August) he has had no return of symptoms.

*Remarks by* Surgeon CLAYTON.—As to the nature of the case there can be little doubt that there was a degenerating cyst in the liver discharging into the alimentary canal. The constant sequence of events—pain resembling biliary colic, followed by jaundice, which was always transient—the effect of morphia—the uniform size of the fragments passed, and the rupture of the larger cysts, strongly suggest: (1) that the cyst was discharging through the biliary passages; (2) that at times portions became impacted, producing the colic; and (3) that by

spasm and irritation or by rupture and discharge of the irritating contents of a cyst into these ducts the jaundice was caused. It may be noted that on two occasions following the pain larger and ruptured cysts have been seen, and the temperature may also perhaps be explained by this rupture of the cysts. The short duration of the jaundice negatives the idea of pressure. The interesting points about the case were as follows: 1. The absence of suppuration, for although the cyst was in direct communication with the bowel no suppuration had apparently taken place in it—a fact, perhaps, due to the direction of the bile-flow and its antiseptic nature. Evidence of this absence of suppuration was afforded by the improvement in his general condition, a gain of 11 lb. in weight since May, by the absence of fever chills or sweating, and so on. Blood examinations carried out at various times with the Thoma Zeiss hæmocytometer show no leucocytosis. The rupture into the bile passages therefore must probably have been a result of pressure atrophy. Other points of interest are to be found (2) in the resemblance of the attacks to those produced by gall-stones and (3) in the possibility that without the examination of the motions this case would have joined the ranks of those undetected unless on the post-mortem table.

## CHILDREN'S HOSPITAL, BIRMINGHAM.

### TWO CASES OF CRANIAL MENINGOCELE TREATED BY EXCISION; RECOVERY.

(Under the care of Mr. LEONARD GAMGEE.)

THE successful surgical treatment of cranial meningocele depends chiefly on the absolute asepsis of the operation, but partly also on the strength of the child, for in this operation the two chief causes of death are septic meningitis and collapse. The use of Morton's fluid is much less frequent at the present time than it was when it was advocated for spina bifida by the committee of the Clinical Society of London.[1] At that time it was probably by far the safest method of treatment, but the surgery of the skull and the central nervous system has advanced greatly since then, and now in suitable cases excision gives much better results.

CASE 1.—A girl, aged six weeks, was admitted into the Children's Hospital, Birmingham, on March 31st, 1898. Growing from the back of the head was a tumour of the size of a large Tangerine orange. The overlying skin was normal in appearance and the tumour could be felt to possess a narrow pedicle, which passed through an opening in the mid-line of the occiput half-way between the posterior fontanelle and the foramen magnum. The swelling was translucent, was partly reducible, and became more tense when the child cried. The child was in other respects healthy and, according to the mother's account, the tumour was increasing in size. Operation was performed on April 1st. A longitudinal incision was made over the tumour and the skin was easily peeled off, the membranous sac, which was found to have a very narrow pedicle, being left intact. The sac wall having been incised it was found to contain clear fluid only and that a canal passed through the pedicle and communicated with the interior of the skull. The pedicle was ligatured with silk and the skin wound sutured. The wound healed by first intention and the patient was discharged from hospital in ten days' time. The child was seen four months after the operation and the condition then seemed to be perfectly satisfactory.

CASE 2.—A boy, aged 11 weeks, was admitted into the Children's Hospital on May 10th, 1900. Growing from the back of the head was a tumour having the same general physical characteristics as the one in the last case. The tumour was attached by a pedicle passing through an opening in the bone situated midway between the posterior fontanelle and the foramen magnum. The swelling was oval in shape and the greatest circumference was 10½ inches. On May 11th the following operation was performed. A skin incision was carried round the tumour a short distance from the pedicle and the sac was incised and found to contain nothing but clear fluid. Through the pedicle ran a canal communicating with the interior of the skull. The sac and the skin overlying it were next cut away. As the pedicle was too broad to be contained in one ligature the opening in the membranes was closed by a continuous silk suture and the skin edges brought together. The wound healed by primary union and the patient was discharged perfectly well at the end of a fortnight.

*Remarks by* Mr. GAMGEE.—The treatment of cranial meningocele by excision of the sac seems to hold out greater hope of success then does that by injection of iodine solution. When the tumour has a narrow pedicle the operation is simplicity itself and it is only when the pedicle is thick that any difficulty is experienced. Even then the difficulty is not great and can be overcome by leaving sufficient of the sac wall to make flaps, which can be sutured together. Unfortunately, it is in comparatively few cases of cranial meningocele that the patient is in a condition to withstand the shock of operation.

# Reviews and Notices of Books.

*Préparation et Coloration du Système Nerveux.* (*Preparation and Staining of the Nervous System.*) Par BERNARD POLLACK. Traduit de l'Allemand par M. JEAN NICOLAÏDI. Paris: Georges Carré and C. Naud. 1900. 8vo, pp. 212. Price 5*s*.

PROFESSOR LAUNOIS provides a preface to the French translation of Dr. Pollack's well-known work, in which attention is drawn to the great advances made in the technical examination of the nervous system during the past 25 years.

In the opening chapter, on Taking Out the Brain and Spinal Cord, Dr. Pollack makes some practical observations which are of special value when these organs are to be submitted to subsequent histological examination. The methods usually employed in dissecting the brain so as to display to the best advantage its various parts are then described. The method of Pitres of transverse vertical sections is rarely used in this country, and yet it is undoubtedly very useful where the brain is to be microscopically examined. The Preservation of the Brain next occupies the author's attention, and here formol necessarily figures largely in the various preserving fluids. The methods of making dry brain preparations, which are very generally neglected in this country, are given at considerable length in Dr. Pollack's book. Laskowski's method with formol is recommended on account of its simplicity. The reviewer has had a considerable experience with Laskowski's method, chiefly using the earlier formula in which there was no formol. This latter procedure can be confidently recommended as producing a durable preparation which shows very little shrinkage and maintains a fairly good colour. The use of formol appears at times to spoil the colour and to increase the shrinking. Dr. Pollack next describes hardening fluids, the different methods of embedding, section-cutting, &c. The important subject of staining is considered under the examination of (1) the nerve-cells; (2) the myelin sheath; (3) the axis cylinder; and (4) the neuroglia. Special sections are given to Golgi's method and to Ehrlich's methylene blue method. The numerous methods are very clearly described seriatim, special attention being given to the more important ones.

The author very wisely follows the plan introduced by von Kahlden of setting out the various points in the methods with the approximate time required for each manipulation. In the section on Golgi's method all the various modifications are fully given. Nothing, however, is said about the criticisms, not always favourable, which have been passed on this method. A full account of the examination of the retina will be found in an appendix. Under the Staining of the Axis Cylinders the author points out and most will agree with him that the methods at present employed here are hardly as efficient as they are for the examination of the other elements. A special section is given to the peripheral nerves. A most useful chapter will be found at the end of

the book in which the author summarises his recommendations and names the methods which are employed in his own laboratories according to the object to be attained.

The practical histology of the nervous system is incomparably more difficult and, at the same time, more interesting than that of any other organ in the body. Hence it is that several guides to this subject have been published by those specially interested in it. It may be confidently stated than none are more efficient than the one which we owe to Dr. Pollack. It is almost indispensable in every laboratory where neuropathological studies receive any attention. The laborious work of translation by M. Nicolaïdi has been admirably done.

---

*Canine and Feline Surgery.* By FREDERICK J. G. HOBDAY F.R.C.V.S., Professor-in-Charge of the Free Out-patients Clinique at the Royal Veterinary College, London. Edinburgh and London: W. and A. K. Johnston. 1900. 8vo, pp. x. and 152. Price 5*s*.

THE greater part of the material comprised in this volume has already appeared as a series of articles in the *Journal of Comparative Pathology and Therapeutics*, and it is fully worthy of being published in this more permanent form. The surgery of the lower animals has kept pace to a great extent with human surgery, and a cursory examination of this work will show that antiseptic principles are fully appreciated by veterinary surgeons. The directions for the preparation of the instruments and the operator's hands are all that could be desired. In animals as in man there are dangers to be avoided in the use of anæsthetics, and we learn that three deaths occurred in 800 anæsthetisations in dogs. It is especially risky to anæsthetise a pug on account of the shape of its nose. Very many operations are described, and they range from the opening of abscesses to the operation for strabismus and excision of the spleen. They are adequately treated, and we find many of the surgical appliances introduced within recent years, such as Makins's clamp and Murphy's button, figured and described. The work also contains a few operations which are not usually required in the case of human beings, such as an operation to cause the ears to droop and amputation of the tail. There are 76 illustrations. The perusal of this volume must prove of much interest to those who are only acquainted with the surgery of the human body.

---

*An Atlas of Urinary Deposits and the Clinical Examination of the Urine.* By LINDLEY SCOTT, M.A., M.D. London: J. and A. Churchill. 41 plates and illustrations in the text. 1900. Pp. 49 + xli. and Index. Price 15*s*.

THIS should be found a most useful book both for the student, the resident medical officer, and the hard-worked practitioner. Examination of the urine has now become, it is to be hoped, a routine practice in every case whether simple or the reverse, and the student should be bred up to such examinations from his first day in the wards. Dr. Scott commences by giving a very clear account of the composition and physical properties of the urine. Next comes an account of its normal constituents and how to recognise them, which is followed by a description of abnormal constituents, of the bacteriology of the urine, and a note upon the examination of the urine in cases of life assurance. The first portion of the work ends with a tabulated description of the characteristics of the urine in various diseases. The plates, many of which are coloured, are accompanied by a clear description and a small key plan. They have all been drawn from actual specimens, with the exception of Plate XXX. which shows the forms of rare animal parasites. The frontispiece shows the variations in colour due to both normal and abnormal pigments.

## JOURNALS.

*The Quarterly Journal of Microscopical Science.* Edited by E. RAY LANKESTER, F.R.S., with the coöperation of ADAM SEDGWICK, F.R.S., W. F. R. WELDON, F.R.S., and SYDNEY J. HICKSON, F.R.S. Vol. XLIII., Part 3. London: J. & A. Churchill. July, 1900. Price 10*s*.—Almost the whole of this number of the *Quarterly Journal of Microscopical Science* is occupied with an elaborate essay by Mr. F. W. Gamble, M.Sc., and Mr. J. H. Ashworth, D.Sc., demonstrators and assistant lecturers in zoology, Owens College, Manchester, on the Anatomy and Classification of the Arenicolidæ. The authors show that there are three British species—A. marina, A. ecaudata, and A. Grübii. They give a detailed account of the structure of these species as well as of A. Claparedii and of A. cristata. Besides the external features usually relied upon by chætopodists they place great reliance on the characters of the otocysts, prostomium, and nephridia taken together. They give a good bibliography of the species and illustrate their memoir by numerous figures contained in eight plates. The second article is by Major Ronald Ross, I.M.S., lecturer on Tropical Medicine, University College, Liverpool, and Dr. R. Fielding-Ould, acting demonstrator at the Liverpool School of Tropical Medicine, and is entitled Diagrams Illustrating the Life History of the Parasites of Malaria. The diagrams are contained in two plates. Professor Ray Lankester contributes a short article on the Morphological Significance of the Various Phases of Hæmamœbidæ.

*The Journal of Anatomy and Physiology.* Conducted by Sir WILLIAM TURNER, F.R.S., D. J. CUNNINGHAM, F.R.S., G. S. HUNTINGTON, M.D., A. MACALISTER, F.R.S., and J. G. M'KENDRICK, F.R.S. July, 1900. Vol. XXXIV., Part 4. With six Plates and Figures in the Text. London: Charles Griffin and Co.—In this number Dr. Christopher Addison, of University College, Sheffield, continues his report on the Topographical Anatomy of the Abdominal Viscera in Man, especially the Gastro-Intestinal Canal. The article gives the results of numerous necropsies and deserves to be carefully studied by those who are frequently engaged in performing abdominal sections. Dr. Alexander Low, senior assistant in the Anatomical Department, Aberdeen University, gives a description of a specimen in which there is a rudimentary first rib along with 13 pairs of ribs and 25 presacral vertebræ. The subject was a male. Mr. Arthur V. Meigs contributes a paper read at a meeting of the Pathological Society of Philadelphia, upon Endophlebitis. Drawings are given of the appearances presented under the microscope. Mr. Walter H. Gaskell, F.R.S., in an article on the Origin of Vertebrates, deduced from the study of Ammocœtes, discusses the origin of the pro-otic segmentation and the meaning of the trigeminal and eye muscle nerves, and also describes the palæostoma or old mouth as well as the olfactory organ and the meaning of the first nerve. He further gives the evidence of prosomatic appendages in Ammocœtes as furnished by the course and distribution of the trigeminal nerve and finally considers the palæontological evidence which he believes demonstrates the Ammocœtes to be a Cephalopod. Two plates accompany this article. The part closes with the Proceedings of the Anatomical Society of Great Britain and Ireland.

*Journal of Balneology and Climatology.*—The July number of this journal contains, among other things, some good papers with reports of discussions thereon, such as those by Dr. A. S. Myrtle of Harrogate on Personal Experiences of Gout; by Dr. H. Laing Gordon on the Climate of Rhodesia; and by Sir Joseph Fayrer on the Hill Stations of India as Health Resorts. Speaking of the climate

and diseases of Rhodesia Dr. Gordon has something to say on the subject of the mosquito and the production of malarial fever. He has been unable to obtain definite information as to the presence of the anopheles in that country, but Dr. Patrick Manson has received specimens from British Central Africa and has little doubt that it will also be found in Rhodesia. Dr. Gordon considers that in all probability this particular mosquito does exist in the lower levels of Rhodesia, especially near to the Portuguese territories, but it is not, he thinks, at all certain that it flourishes in the elevated districts where malarial fever is undoubtedly also endemic to a certain extent. He quotes some evidence from Enkeldoorn in Mashonaland connecting the malarial fever with soil changes and decaying vegetable matter and with the overturning of virgin soil in farming. He also gives facts regarding the great prevalence of malarial fever among the police in Bulawayo, a prevalence apparently attributable to their improper housing and exposure during the wet season, as shown by the great improvement which ensued on these conditions being removed. The principal medical officer of Rhodesia asserts that the fever is rapidly becoming less frequent, if not unknown, in the towns and centres and that it has also altered to a much milder type. In the discussion which followed the reading of this paper several speakers took part. Dr. A. P. Hillier, who had been 13 years in practice in South Africa and had since been in close correspondence with several of the colonists in Rhodesia, described his experience. Although he cordially recognised that there was no more brilliant piece of original research work than that connected with the investigation of the malarial parasite and its history, he confessed that the occurrence of malaria in South Africa, and especially in Rhodesia, had caused him considerable speculation. Rhodesia, he explained, was a very thinly-populated country and had an area of something like 150,000 square miles, and some of the low-lying malarious districts were uninhabited. If the mosquito be entirely dependent upon man for its stock of the malarial parasite, how and where was it obtained? Certain it was, nevertheless, that casual visitants, such as sportsmen and explorers, to these low-lying districts contracted the malarial fever there from which they very soon afterwards suffered. These and other points, such as why the anopheles should be the only variety of mosquito which acts as the medium for its spread, require to be, as they probably will be, cleared up by future researches into the genesis and life history of the mosquito.

# New Inventions.

## CHINOSOL ANTISEPTIC EQUIPMENT.

THE Chinosol Hygienic Company, of 36, St. Mary-at-Hill, London, E.C., are introducing a series of neat cardboard cases containing an assortment of Chinosol preparations adapted for various antiseptic, deodorant, and disinfectant purposes. The box sent to us contains one bottle of pure Chinosol powder, one bottle of five-grain tablets, one bottle of eight-grain tablets, one bottle of bath and toilet tablets, and two tins of sanitary tablets each containing 45 grains of crude Chinosol. The series includes five boxes, No. 1 to No. 3 being for medical and surgical purposes, No. 4 for hygienic and toilet purposes, and No. 5 for the extemporaneous preparation of a concentrated disinfecting fluid. The powerful disinfectant properties of Chinosol have been established, and this salt possesses many advantages over other preparations, as it is freely soluble, practically odourless, and unirritating.

# THE COST OF MEDICAL EDUCATION.

IT was for several years our habit to place before our readers an estimate of the cost of medical education. We did this that those interested in arriving at the whole amount of this expense—which is by no means limited to such obviously necessary payments as fees, board, and lodging—might have some trustworthy materials before them on which to found a decision about joining a medical school. We obtained our original information from personal communications as answers to a schedule of questions placed by the aid of the deans and registrars of the various medical schools in the hands of a certain number of selected students, who were requested to furnish in the form of replies the data from which a general statement could be prepared for the guidance of others. Although the habits of the individual students necessarily had a great, even a preponderating, effect upon the replies the returns were sufficiently numerous to yield averages, and it was easy to see that the average man spent more money in the metropolitan centres than in the provinces, and that the standard of living and the cost of maintaining a given standard varied from place to place. The most complete statement that we received came from a provincial student, whose great economy in the matter of personal expenses could only be looked upon as an example to distinctly follow. It would have been unfair to expect that every student could live so frugally as to support himself and pay for rent and food (ten months), clothes, washing, recreation, fees, and even "incidental" and "unaccounted" expenses on the small annual sum of £65. But these headings will serve as a plan upon which we can discuss the subject generally—premising that only general information can be given that is worth anything, as a medical student as much as any other young man can make his expenses as large as he wishes, while he can only reduce them to the point that is permitted by the circumstances under which he is studying.

The cost of *rent* is the first item to be considered, and naturally enough is a charge which varies greatly with the locality. A student who occupies rooms in desirable quarters of London will pay from £2 to £3 a week on this account alone, whilst in many large provincial centres lodgings are almost as expensive as they are in London. But such rents are generally shared between fellow students, who make one sitting-room go with two or three bedrooms. We may take it that a student's rent for furnished apartments ought not to amount to more than one-quarter of the sum that he can fairly count upon receiving as income. If his parents can allow him £150 per annum (a large sum and one that is beyond the power of the parents of many medical students to set aside for one child) his rent should not be more than £1 a week. We are calculating that he will reside at his particular centre of education for about ten months during the year. In London it is not always easy to live near the hospital and obtain lodgings for much less than £1 a week, so that if a student can only expect £2 a week from his parents he is absolutely compelled to spend an imprudent proportion of his income in rent. Clearly none of this applies either to the students who live with their parents or those who are studying at a university for an arts degree concurrently. Nothing more definite on this subject can be said than that a careful man can live as a medical student on £80 per annum if he does not spend more than 10*s.* a week on his lodgings; but he will not always find it easy to obtain the lodgings, and every shilling above this weekly sum will make it very hard indeed for him to make both ends meet.

Referring to other centres, the rent of lodgings in Edinburgh is considerably less than in London, but in Dublin it is about the same as in the English metropolis. The cheaper quarters of Dublin are more than unpleasant to live in; they are positively dangerous in many places from their lack of proper sanitation. In Edinburgh there is a sort of residential club known as University Hall which affords facilities of social intercourse and mutual aid, as, for example, in the lending of books, which is practised systematically among the resident students. In addition to these amenities, the institution secures them lodgings at a very moderate monthly rent. Glasgow lodgings again run at about the same level, whilst in Birmingham rent is

cheaper still. The cheapest district of which we have any full information is Aberdeen, where both in the matter of rent and of food we have heard of an economy that is altogether exceptional, 3*s*. 6*d*. a week in summer and 4*s*. 6*d*. in winter, the additional shilling representing the cost of fuel to cope with the Scottish winter. And a shilling will not go far this year when spent in coal. In towns like Cork and Leeds the average rises above this limit, but 15*s*. a week is a somewhat high charge. In the Irish provincial towns the rent of rooms is very low, 5*s*. and 6*s*. being by no means below the average. A somewhat higher rent is asked, but still ranging about 10*s*. a week, in English provincial towns which are in possible touch with a medical school—such as Stockton, or Rugby, or Devonport; but residence in these involves constant railway travelling, and would hardly be adapted for the purposes of a student's career, unless some special considerations influenced the decision with which fine questions of comparative expense would not come into competition. The lodging accommodation afforded by residential colleges, hospitals, and the like institutions should be mentioned. But concerning these a word may suffice. The advantages of residence in a college are manifold, but they are chiefly of the intellectual and social kind. The cost is not less than that of private lodgings thriftily selected. There may also be in some instances impatience on the part of the student of the control imposed by the regulations, which are necessarily devised for the orderly conduct of such institutions. Nevertheless, the select society, and even the inevitable restraint, of such institutions are of great service, especially to young students, who have reason to dread nothing more than solitude and an irresponsible control of any considerable proportion of their own time. On the other hand, the cost of board and lodging in such institutions is not greater than the average cost of the same accommodation in private lodgings in their neighbourhood. A plan that involves no inordinate expense is to place a student in the house of a medical practitioner in the neighbourhood of the school which he is attending. It will be found that when the educational facilities thus placed in his way are taken into account, in addition to the mere commercial value of his board and lodging, the arrangement is usually a very economical one. The opportunities for doing this are, of course, not unlimited, but they are sufficiently numerous to merit mention here. A word of warning must be added. Every man who is willing to receive a student into his house and who offers advantages in the way of private tuition may not be capable of carrying out his promises. The modern curriculum is a severe one, and the preliminary scientific work is more arduous than it was even a decade back. We recommend that the advice of the dean of the school be asked before any bargain is entered upon to place a student with a gentleman who offers board, residence, and tuition to his charges.

Passing to the next heading, that of *food*, we may observe that here again nothing can be said precisely, but we can indicate the minimum sum that can be spent, and variation from this sum must be dictated by the student's purse. The prevalence of high prices or of low prices, as the case may be, affects such figures very little, and we may say that £30 is, we consider, in London the least sum that will meet necessary expenditure on good food. There will be no real economy for student or parent in the attempt to save in this item. We again refer only to ten months in the year. Food at the present moment, like everything in this country, is tending to become more expensive because of the rise in the price of coal.

Lastly, with regard to *fees*, the composition fee which is published by the various schools, and is in a sense a comprehensive charge, may easily be supposed to be more comprehensive than it is. A glance at our tables will show exactly how it is arrived at and what it covers. Broadly, it may be said to include all the professorial fees; but it does not include *books*—that is a matter of course. Equally it does not include *instruments*, and these two items together cannot be fairly written down at less than £8 a year in an ordinary case. We published in our issue of Sept. 1st, p. 646, a brief list of selected books with their prices which, or their substitutes, the student will require to read. He will, of course, follow the advice of the teachers of his school as to the value of any particular manual, while a much larger selection will be found in our Students' Number of Sept. 3rd, 1898, p. 657, *et seq*. Many circumstances may occur to falsify the estimate of an annual expenditure of £8 in books A successful student may largely supply himself with books by prize-winning, or access to a suitable library may minimise his personal requirements in this respect. With instruments, bones, parts for dissection, and the like, the case is somewhat different, and the expenditure under these heads can only be avoided at the expense of the student's education. A niggard hand in such matters makes therefore a grievous mistake, and this should be clearly appreciated at first, otherwise the temptation to undue parsimony will be supported by a grudging mind. Another item which is for very good reason omitted from the composition payment is the *charge for examination fees*. The reason of this will be at once apparent if it is only considered that the teaching bodies and the examining bodies are distinct, and that whereas the composition fee represents a sum payable to institutions of the former class the examination fees are receivable by institutions exercising the examining function. It will be hard to quarrel with an arrangement which is justified by the importance of paying the fee to the right person. Less obvious, but of the same kind, is the explanation of the circumstance that *tutorial* fees are not included in the composition. Many students pass through their curriculum by the aid of lectures and professorial instruction only. This is very possible when only pass examinations are attempted; but for competitive examinations additional instruction is sometimes an indispensable preparatory. Such additional instruction must of course be paid for, but its occasional character prohibits its inclusion with the indispensable items in the comprehensive payment.

To sum up, we have this position: The minimum sum that a student must be prepared to spend in London during a year on board and lodging is £60, though £50 will cover his expenditure in these directions in other centres, and less if he is careful. He can save 20 per cent. of this expenditure by living with a fellow-student to their mutual benefit. He must be prepared to spend £10 more at least in books, or instruments, or both. He will be almost the exception if he does not incur one or two extra liabilities in the way of special tuition during his five years' career. He will require another £10 a year as pocket money, and to these figures must be added his fees and the price of his clothes. We do not think that in London any young man should be asked to attempt to maintain himself entirely and pay all necessary fees and expenses of education as well upon a less sum than £100 a year. That many receive less, and, to their infinite credit, make it suffice and crown the self-denial of their youth with a success that is sweetened by the struggle to obtain it is undeniable; but many more of their fellow-students receive larger allowances and find them inadequate. Upon individual instances, with their innumerable reasons for special treatment, we do not attempt to dwell, and we desire our readers to remember that, roughly speaking, the figures which we now give for London are a little, perhaps 15 per cent., in excess of those that with the practice of economy would be found to apply to the provinces, Scotland, and Ireland.

If a student cannot command personally or by allowance from his parents £100 per annum, and look to receiving it regularly for at least four out of the five years of his curriculum, we consider that he is rash in these exacting days to embark upon our profession. These are almost identical with words that we have previously used in treating this topic, but no alteration in prices or conditions makes them less true.

---

HEALTH OF BRISTOL.—At the meeting of the Bristol Health Committee held on Sept. 4th the medical officer of health (Dr. D. S. Davies) reported that during the past five weeks 202 cases of scarlet fever had been notified (against 41 for the corresponding five weeks in 1899), 51 cases of diphtheria (compared with 15 in 1899), and 32 cases of enteric fever had been notified (against 24 for the preceding year).

TYPHOID FEVER AND COCKLES.—At the meeting of the Exmouth Urban District Council held on Sept. 5th the medical officer of health reported that after a careful examination of the recent cases of enteric fever which were attributed to the consumption of cockles he was of opinion that in four cases the evidence was conclusive. He added that every legal measure had been adopted by the Exmouth sanitary authority to prevent the sale of such cockles, but there was some difficulty in taking legal measures, as the Public Health Act scarcely provided for such a situation.

# THE LANCET.

*LONDON: SATURDAY, SEPTEMBER 15, 1900.*

RECENT events in Glasgow with regard to plague are instructive in several ways. The first fact that we are met with in the history of the outbreak is that the original cases of imported plague are not to be traced. The earliest known cases occurred among Glasgow people whose relation, if any, with persons or articles newly come from foreign countries cannot be determined. In other words, the enemy somehow or other eluded the outposts, which in this instance are provided by the system of medical examination of persons arriving at our shores from infected or suspected ports. The next fact is that once the occurrence of plague was established the whole forces of resistance at the disposal of the municipality of a great city, organised by one of the best public health departments which we possess, were at once brought into action. The procedure employed—viz., prompt hospital isolation, medical house-to-house visitation, formation of "cleansing areas," search (with the aid of bacteriology) for cases bearing suspicious similarity to plague, observations of "contacts," along with other administrative measures—was detailed in our last issue. The success that has met this procedure is not open to doubt. Two or three new cases, as was almost to be expected considering that the means of introduction of the plague is unknown, have occurred this week, but there is every reason to consider that the outbreak, if not at an end, has been brought fully under control.

How much can be done by sustained application of well-considered preventive measures when plague appears in a populous British community may also be judged from the account which we print elsewhere of the action taken in Sydney. In this city of nearly half a million inhabitants, including a small Chinese quarter, cases of plague have occurred week after week for nearly six months. Yet, owing to the determined efforts of Dr. ASHBURTON THOMPSON and his staff, the total number of plague cases which occurred during these six months has been scarcely more than 300, and by now the disease appears, for the time at any rate, to have been completely eradicated from the great Australian city. The circumstances of the outbreaks in Glasgow and Sydney give point to certain considerations as regards plague upon which we have more than once insisted. Good as we believe the arrangements made by the port sanitary authorities round our coasts to be, and watchful as we know the port medical officers and the medical department of the Local Government Board to be for cases of imported plague, it is almost certain, from the nature of the disease, that cases will from time to time escape their vigilance. There never were outposts that could not be penetrated. It is essential, therefore, that all sanitary authorities should be prepared for the possible appearance of cases of plague in their districts, whether brought from over-sea or by persons or articles coming from infected places within our island. A little forethought in this direction is the one way to prevent the alarm and panic which the word "plague," with all its seventeenth-century associations of marked doors, death-carts, and plague pits is liable to produce on the public. So far as we know it in colonial and European populations, plague is a disease particularly amenable to preventive measures to the exercise of which we have long been accustomed. Plague does not, like cholera or typhoid fever, become suddenly and widely epidemic through pollution of water-supplies; its ability to infect a population by passing from person to person is limited to a far greater degree than obtains, for example, in the case of scarlet fever; while the infection of plague is clearly not capable of being carried considerable distances aërially, as is that of small-pox and possibly also that of measles. The disease which furnishes to the physician the nearest analogy to plague as regards its method of spread is typhus fever, and the conditions which permit typhus infection—overcrowding, dirt, lack of air, and the like—also seem almost essential to the spread of plague. Rats and fleas, so much considered of late in this connexion, no doubt may in some cases play an important part in propagating the disease. But in this country the opportunities of the rat infecting man after all are not many, while the flea, to produce infection, must needs have come from a person or an animal whose blood contained the plague bacillus—a chance which, save in a severe plague epidemic, may for the common purposes of life fairly be disregarded.

Public health authorities, and therefore the public under their charge, have no excuse for panic, and it is welcome news that signs of panic are difficult to discover anywhere. But every preventive precaution should be taken. We are glad to note that public health authorities all over the kingdom are setting in motion the ordinary means for combating infectious disease, and that the public recognise that measures should be taken before, and not after, a local scare of plague has set in. Some isolation provision should be in readiness whenever such provision is available, efficient disinfection should be practicable, and suspicious cases should be sought out. Few of our towns have the resources of Glasgow, but save for the extensive isolation of "contacts" (which is perhaps the least essential of all the measures there adopted) every place should, if it has any claims to sanitary efficiency, easily be able to take the steps which are needed. Above all, it should be remembered that the best means for prevention of plague, along with a host of other diseases, is steady perseverance in that everyday sanitary work of a community which endeavours to ensure cleanliness, light, and pure air to its members. One other important lesson that may be learnt from the Glasgow experience is the extreme value of the coöperation of the medical practitioner with the health authorities. To the acumen of Dr. THOMAS COLVIN in recognising the suspicious character of the earliest cases Glasgow probably owes much. At this time it would be well in practice to be prepared to entertain the idea of plague, notwithstanding the absence of the disease from the locality where any patient presents suspicious symptoms, and the

lack of any history of his exposure to possible plague infection. If a spirit of precaution as to infectious disease should be the result of the outbreak of plague in Glasgow, that outbreak must be regarded—of course from the strictly medical point of view—as no bad thing for the nation. It is giving sanitary authorities everywhere an excuse for furbishing their weapons against epidemics and strengthening their resources; while it is bringing home to the populations under their charge the fact that terrible disasters can be averted by prompt measures, and particularly by being in readiness against the foe.

---

THE movement in favour of hospital reform, which has at various times received much attention in our columns, has for its principal objects the improvement of the general administration of hospitals and the devising of means to prevent misapplication of their benefits. Financial questions may for the most part be safely left to the managing committees of these institutions, who have every incentive to practise economy; for in these days of manifold calls on the purses of the benevolent the stream of charity tends to become broken up into many channels and individual subscription lists feel the effects accordingly. Direct financial questions, however, do not often arise, the funds of most of these charities being excellently administered. The great trouble, as all our readers know, is what is termed hospital abuse. During the last 50 years hospitals have everywhere undergone numerous changes for the better. The dietary is liberal, the cooking is superior to that in many middle-class homes, the personal comfort of the patients is studied, the nursing arrangements are as efficient as those provided for the favoured ranks of society, and the medical men in attendance are, as a rule, the leaders of the profession in their locality in town and province alike. Moreover, class distinctions are now less obtrusive than formerly and the spread of education has imparted a certain amount of refinement to the behaviour of the poorest, so that contact with them no longer corrupts good manners. The natural result of all these causes is that a section of the public, which in other matters would resent being told that they were depending on charity, do not hesitate to betake themselves to the hospitals in time of illness, regardless of the fact that they are thereby competing with and displacing those who are socially much beneath them. The benefits of these institutions are in this way apt to be lamentably misapplied, and the weak spot of our hospital system is that such misapplication is possible. But the difficulty is inseparable from the existence of voluntary hospitals supported by charitable contributions. Charitable contributions are for the benefit of the poor, and if applicants who do not belong to this class are to be excluded inquiries into the circumstances of some patients must be made. If these inquiries are thoroughly prosecuted a great deal of abuse can be prevented; but the investigation into the social status of applicants for hospital relief is apt to be perfunctory, while it is very easily defeated by a little ingenuity on the part of the would-be patients.

Various methods have been suggested for the purpose of reconciling these conflicting interests, or at least of reducing the points of divergence. One of them, which has been put forward again and again with many specious arguments, would abandon the principle of support by voluntary subscriptions and would substitute State aid or maintenance by grants from the rates. Then everyone would have a right to demand from the hospital the assistance for which he had paid in proportion to his means and position. To this proposal there are many and obvious objections, but nevertheless some of the inhabitants of Aberdeen are anxious that the constitution of the Royal Infirmary in that city should be thus modified. Our Aberdeen correspondent writes that at a meeting of the "Citizens' One-Plank" Committee, held early in the month, a report on the proposed municipalisation of the Royal Infirmary was submitted by a sub-committee, in which it was contended that the system of voluntary support was wrong in principle since it allowed a large section of the citizens to evade their responsibilities towards the sick members of the community, while it also left the institution hampered for want of funds. A resolution was thereupon adopted to the effect that "this committee is of opinion that the only way of making adequate provision for the sick is by having the management of the infirmary placed in the hands of some popularly elected board with statutory rating powers at its disposal, and resolves to take whatever steps may be necessary to have that object realised." The "Citizens' One Plank" Committee is in ignorance, surely, of the meaning of its resolution. Our great hospitals are for the most part institutions of long standing, which have become what they are by a process of slow growth and development. They have not only their history but their traditions, they are capable of inspiring *esprit de corps* among those who are connected with them, and they are regarded not without pride by the people to whose needs they minister. They would not retain the same hold on local sympathies or on the popular mind if they became rate-supported institutions. No longer would they attract the money of the rich or the best efforts of the medical profession. They would fall under the benumbing influence of officialism.

Voluntary hospitals existed centuries before the care of the sick and disabled poor became a subject of national concern to be provided for from the public funds. Some of them have been largely endowed by private benevolence long ago, and the financial difficulties of others have seldom failed to bring forward friends who make increased efforts in their behalf and take proportionate interest in their usefulness. Without the aid of energetic individuals working in association and prompted by generous zeal for the relief of distress our hospitals could never have attained their present position. For undertakings of this kind have many sides, they must not be judged by merely commercial standards, and some of the essential attributes of a hospital, some of the features in the treatmen and after-care of the sick, would have but scanty recognition in the routine methods of a public department. For a hospital to be in all respects a success a certain kind of prestige is necessary. The community should feel proud of the treatment which the hospital affords, and the medical staff should be animated with an intent to keep the fame of the institution untarnished. No such sentiments would be present in the case of rate-supported hospitals which would be regarded with the critical eye that is always turned upon municipal

enterprise; which would be extravagantly managed—for are not public enterprises invariably more expensive than private?—and which would be unenthusiastically served. Again, under our present system those of the subscribers who gravitate towards the governing body are for the most part the right people, but who can suppose that this desirable feature of merit would count for anything in the turmoil and competition of municipal elections? The man who could pull the most strings might find himself chairman of the board of management of a hospital while completely devoid of general sympathy for science, of special sympathy for the sick poor, or of elementary knowledge of hospital management. We deplore deeply the fact that many of our voluntary hospitals are in grave financial difficulty, but we cannot think that the views of the "Citizens' One Plank" Committee of Aberdeen are right.

---

IN the very happily-worded address delivered by Mr. EDMUND OWEN before the Canadian Medical Association on Sept. 13th, of which an abstract appears at p. 789, occurs the following sentence: "It is a good thing for a surgeon now and then to get away from pathologists and morbid histologists. In recent years there has been, perhaps, rather too much inclination to apotheosise the morbid anatomist, who, standing high in his suit of sable, looks upon the clinical surgeon as if his chief duty were to supply him with material." In THE LANCET of Sept. 1st, at p. 717, appeared a letter from Dr. POWELL WHITE defending the thesis that pathologists should hold a much more important position than they do at present, and a letter couched in similar terms appears to-day at p. 840. It is difficult—nay, even impossible—in a complex science dealing with a complex organism like the human body to decide which if any one department of that science is the chiefest. A steam locomotive cannot get on without fuel and water, but these two, though essential to its well-being, are no more so than wheels or cylinders. Further on in his address Mr. OWEN made the *amende honorable*, if such were needed, to the pathologist for the value of his work; but there undoubtedly is a danger in the case of the younger members of the profession of laying too much stress upon the results of post-mortem and microscopic or inoculation experiments. In the patient there is that mysterious $\pi$ which can never be evaluated—namely, the quality or condition known as life—and this is apt to upset all the results which should happen according to the teachings of pathology.

On the other hand, the light that has been thrown on disease by research in the laboratory of the pathologist is brilliant beyond our power to exaggerate, for to the patient and laborious investigations undertaken in the study of pathology must be assigned by far the greatest share of the credit for the modern enormous advances in surgery, and this is true not only of the surgery of the present day and of recent years, but equally of the surgery of the latter half of the eighteenth century when it may be said that scientific surgery had its beginning. And especially has the work of the bacteriologist been of untold value to surgery. The study of micro-organisms during the last 50 years has done much to assist in the diagnosis of disease, in rendering exact the classification of maladies, and in distinguishing between closely allied conditions, and in so far as treatment depends on diagnosis the aid afforded by the bacteriologist has been definite and valuable. In treatment itself the advances in bacteriology have been of less moment if only because the conditions existing in the human body cannot be reproduced in the laboratory. Nor can we measure the recuperative powers of the body. The *vis medicatrix naturæ*, the power which the body possesses of resisting and overcoming the invading microbe, is of more account in the struggle with disease than many of us are ready to think; and Mr. OWEN in his address called the attention of his hearers to the great tendency towards recovery which is manifested by so very many cases of tuberculous disease. This is most clearly to be seen in some varieties of tuberculous disease of bone in which, from the situation of the lesion, no direct operative treatment is possible. If, as Mr. OWEN points out, a case of caries of the spine is taken under treatment early a very excellent result with a minimum of deformity may be obtained. If the case is not seen till later deformity cannot be prevented, but the patient may recover, and enjoy, though with a permanently deformed spinal column, a long life free from disease. Three years ago a tendency to heroic measures showed itself in the treatment of some of these cases of extensive spinal caries, and the professional and no small portion of the lay press were flooded with wonderful and almost horrible illustrations of the procedures advocated for the "immediate" reduction of these "gibbosities." Yet, except for here and there a slight notice of the benefit derived from this treatment, the medical profession has received no definite statement from the introducers and advocates of this treatment as to the ultimate results of such severe procedures. The time has certainly come when the profession has a clear right to be informed as to the present condition of those patients who were treated three years ago by forcible reduction of spinal curvature. Whatever the result has been it should be published.

Not the least important part of Mr. OWEN'S address was concerned with the prophylaxis of tuberculosis, and certain words which he spoke to his medical audience ought through them to reach the public. The value to Great Britain of the prevention of tuberculous disease is very great, for it is one of our greatest scourges, while Canada has a high death-rate from this cause. If phthisis is to be prevented the work of prophylaxis must be accomplished by the public. It must not be regarded as a matter with which medical men only are concerned. They, indeed, have their portion of the work and this they perform when they lay down the rules that should be followed, but it is the business of the people themselves to carry out these rules. Without the earnest coöperation of the people the extinction of tuberculosis is impossible. On only one of the methods to this end did Mr. OWEN speak, but he laid down clearly the rule that, save in exceptional cases, those who are undoubtedly tuberculous should not take upon themselves the responsibility of parentage. This is only one of the methods of prevention of tuberculosis, but its obviousness should appeal to everyone.

# Annotations.

"Ne quid nimis."

## THE MANCHESTER SEWAGE PROBLEM.

THE Manchester Corporation have at last made up their mind to deal with the difficult problem of sewage disposal, and, to their credit be it said, have adopted a scheme which not only deals with the question for the time being but will do so for some years to come, and one which also meets the requirements of the Local Government Board. At the meeting of the council on Sept. 5th the Rivers Committee submitted two schemes, one based on the report of three experts and one based on the requirements of the Local Government Board. The cost of the first was estimated at £337,000, and of the second at £487,000. Sir Bosdin Leech, chairman of the Rivers Committee, introduced the subject in fulfilment of the promise to bring both schemes before the council. These plans (he said) had been prepared by Mr. Wilkinson, and it was for the council to decide which scheme was best suited for the disposal of their sewage with efficiency and economy so as to satisfy the Local Government Board and the Rivers Committee. He stated that the question was urgent and of supreme importance to the welfare of Manchester. Dealing with the experts' scheme he said that it was the result of 15 months' experimental work. The Local Government Board, on the other hand, insisted on the purchase and laying out of land at Flixton and Carrington and the provision of 50 per cent. more filter-beds, because the Board doubted whether the beds would retain their capacity and considered it imperative that the Manchester Corporation should be on the safe side whatever the cost might be. It was quite possible that not more than from 30 to 50 per cent. of the bacteria beds asked for at Carrington would ever be put down, because if in the progress of the work it was proved that the experts were correct and the extra beds were not necessary the committee were encouraged to believe that they would not be called upon to provide the full number of contact beds, and in that case there would be a saving of from £60,000 to £100,000. He further stated that any scheme which did away with the need for chemical precipitation effected a saving of £7000 per annum or a capitalised sum of £200,000. With regard to the cost incurred by Manchester in dealing with its sewage he pointed out that whereas Manchester spent 8*s*. per head of the population on works for purification of sewage, exclusive of sewers, Birmingham had spent £1 8*s*. 3*d*. and Wolverhampton £1 10*s*. 5*d*. At Derby, moreover, they were proposing to spend a sum which will add 4¾*d*. in the pound to the rates of that town. So far Manchester had spent £223,000. 4 per cent. on this (including sinking fund) represented ¾*d*. in the pound and assuming that the council spent a further £487,000 it would only mean a little over 1½*d*. in the pound, because a sum of £19,480 would meet the cost of interest and sinking fund. As an alternative they were threatened with a fine of £50 a day, or £18,250 a year, and at the end they would not be one step further on their way towards purification. The scheme devised to meet the requirements of the Local Government Board was cheaper in many respects than the alternative plan. The cost of dealing with the storm-water was £8000 less, and by spreading the works over a larger area the pick of the land was obtained and the excavation reduced. The increased cost of No. 2 scheme was owing to the provision of 92 acres of filter-beds at a cost of £264,500, instead of 60 acres for £194,700, as designed in No. 1 scheme. To the difference, £69,800, must be added the cost of laying out the land at Flixton and the syphon under the Mersey, £20,200, and the conduit, £22,600—in all, £112,600, which was practically the difference between the two schemes. One on the ground of safety provided land and works in advance of present requirements, the other land only. For maintenance, No. 1 scheme would cost £16,805 per annum and No. 2 would cost £20,000. This latter was roughly the amount spent at Davyhulme now for maintenance, including precipitation. The majority of the Rivers Committee favoured No. 2 scheme, but they would carry out loyally whichever scheme the council passed. Sir Bosdin Leech concluded his speech by stating that the Rivers Committee "want to have the question settled. Laboriously and long they have honestly sought after light and truth. They desire to see Manchester take her right position in the van of progress even in sanitary matters, and they ask their colleagues in the council to give them their assistance and decide which scheme should be adopted." An attempt was made to seek Parliamentary powers to carry out the culvert scheme but this was lost by 18 votes to 42. A resolution to carry No. 2 scheme or that of the Local Government Board was carried, and also a resolution asking the Local Government Board for their sanction to borrow under the Public Health Act of 1875, on security of the city rate, a sum of £487,283 17*s*. 4*d*. for the carrying out of the scheme.

## THE WINDOW, THE ROOM, AND THE SUN.

THAT light is an essential of health has long been recognised vaguely, but we are now gradually learning to some extent to what the health-giving properties of the sun's rays are due. The depressing and demoralising effects of darkness have been known from time immemorial, and the dungeon was perhaps the worst form of punishment to which a human being could be subjected. It is only comparatively recently that attention has been given to the necessity of providing an abundant supply of unfiltered light as well as air to our dwelling-places. A little over half a century ago many of the tenements of London were no better than dungeons from the point of view of the provision made for the entrance of light. Indeed, as is well known, glass windows were taxed, this action of the State being itself an incentive to darken the house. The question remains how best to secure the health-giving properties of light whilst excluding variable conditions of weather which would give rise to discomfort. In a paper upon this subject which was read at the recent meeting of the Tenth International Congress of Hygiene and Demography in Paris M. Trélat, a well-known authority on hygiene, gave it as his opinion that the best light for the house is the slanting light as opposed to the vertical and the horizontal lights. Of course the light proceeding in a straight line from the zenith could not be made available, while the light proceeding in a straight line from the horizon, as at sunset, similarly could not be utilised, besides which this light is not so pure, for, as M. Trélat holds, it is deteriorated by passing through successive layers of dust and vapours escaping from the soil. According to this view houses should be constructed to receive the rays of light at an angle of 30 degrees—that is to say, from a space corresponding with the mid-heavens—and, in order to obtain this light, houses should not be higher than two-thirds of the width of the street. If a street, for example, were 30 feet wide the houses on each side should not be higher than 20 feet. We are afraid that there are very few houses and streets complying with this standard. The suggestion is, of course, not to cut down our houses, but to widen our streets—a suggestion with which everybody would be in accord were it possible economically to carry it out. The question of the presence of microbes at different air levels must not, however, be ignored. Bacteriological experiments have shown that the

air near the ground is loaded with micro-organisms, the number diminishing as we ascend. The difference is most marked even in the case of a five-storey building, the air in the top storey being comparatively free from microbes, while that on the ground-floor swarms with them. This state of things would be altered if the sunlight were admitted properly on all floors, for sunlight is a powerful bactericide.

## THE FOOD PRESERVATIVES COMMITTEE.

DR. H. T. BULSTRODE, of the Food Preservatives Committee, and Mr. C. J. Huddart, its secretary, have visited Amsterdam, Hamburg, and various places in Denmark for the purpose of studying the dairying industry and the methods of transport of dairy produce, with special reference to the milk and butter supplies in Holland, Germany, and Denmark, and the butter export trade, in relation to the use or non-use of chemical preservatives. The committee and their secretary are proceeding to Ireland during the present week with a like purpose in view, and propose to give special attention to the south and west of Ireland, although visits will also be paid to the province of Ulster in the same connexion. The Committee will probably spend the rest of the month in studying the above matters in Ireland prior to reporting.

## TUBERCULOSIS IN THE RUSSIAN ARMY.

IN a paper compiled from official sources by Dr. H. K. Chtchepotiev and published last February in *Vratch* the sick-rate from tuberculosis in the Russian army during the octennium 1890–97 is said to have amounted to 4 per 1000 annually and the death-rate to 1·07 per 1000. Contrasting these high rates with the condition of things prevailing in other countries the author finds that the annual admission rate for tuberculosis in the German army is 2·3 per 1000 of strength, in the Austrian army 3·4 per 1000, and in the French army 5·0 per 1000, the death-rate varying from one-sixth to one-third of the total mortality from all causes. In the French army, according to Makiewicz, out of 1000 soldiers invalided for tuberculosis 116 had acquired the disease before enlistment, while 197 developed tuberculous symptoms during the first six months of their service and 278 during the second. In the course of their second year 254 more were found to be affected, leaving only 155 who remained immune until they had served two years and upwards. At Kiev Dr. Chtchepotiev found that during the period from January, 1895, to November, 1899, the number of admissions to the military hospital on account of tuberculosis was 527. Of these 111 men had less than six months' service and 32 less than a year. The second year furnished 127 tuberculous cases, the third 111, the fourth 95, the fifth 33, and the sixth and upwards 18. 12 of the young soldiers in the first series died in hospital, the remaining 99 being sent to their homes while still able to travel. Dr. Chtchepotiev is strongly of opinion that the great prevalence of tuberculosis in the Russian army is due to the entry each year of a number of recruits who carry in their systems the seeds of the disorder. Although a great many of the affected soldiers have tuberculous antecedents, hereditary or otherwise, it is also true that of the men attacked after serving a year or more fully half are strong and robust with nothing about them to suggest predisposition or the inheritance of a family taint. Unfortunately it is not always an easy matter to recognise incipient phthisis pulmonalis. A recruit who presents easily diagnosed symptoms of tuberculosis can to a certain extent be guarded against, but the harbourer of latent germs is a veritable *anguis in herba*. Living as soldiers do more or less promiscuously, sleeping in numerously occupied dormitories where they must inevitably respire air that has already passed through human lungs, it is of the utmost importance that every one of those lungs should be as sound as possible. In order to completely eradicate tuberculosis from the army the most strict inquiry into the previous medical history of every recruit should be insisted on and provided for, together with a far more searching examination of his physical condition than at present obtains. The small additional cost thus entailed would be recouped over and over again, even though but a quarter of the present loss of efficiency from a preventable cause were to be attained. As a palliative it would be well to provide for the early elimination of tuberculous subjects. At present the custom in the Russian army is to retain them as long as they can manage to carry out their duties. Incidentally Dr. Chtchepotiev confirms the fact already noticed by several writers, that Jewish soldiers are seldom the victims of tuberculosis.

## OVERLYING AS A PENAL OFFENCE.

CASES of overlying have hitherto been dealt with exclusively in coroners' courts, though the opinion has long been gaining ground that this mischievous practice ought in some way to be brought under the control of the criminal bench. Neither does it seem necessary for this purpose to have recourse to special legislation. The fact that death has been caused by overlying is in itself an evidence of parental negligence. There may be cases so purely accidental and so painful in the memory of the bereaved parents that further interference than that of the inevitable inquest would be injudicious. One which was recently investigated at Worship-street Police-court does not come within this category. The mother had already lost two other children in the same way and could not fail to be fully aware of the danger to which she exposed her children by taking them to bed with herself and of the very moderate amount of care which would provide them with a separate sleeping-place. It is not surprising that this woman was committed for trial at the Central Criminal Court. The case, whatsoever its issue, may help to quicken in some callous parents a sense of their responsibility and to arrest a far too prevalent cause of infant mortality.

## THE METROPOLITAN WATER-SUPPLY.

THE Water Examiner appointed by the Local Government Board has just issued his report on the condition of the metropolitan water-supply for the month of July. The Thames water, he says, was in good condition during the whole of the period. The amount of water passing down the river was below the average; at its highest flow the level was three inches and at its lowest nine inches below the average summer level. The daily average of water supplied per head was 40·59 gallons. In regard to the amount distributed by the different companies the Chelsea, Grand Junction, Kent, and New River supplied during July, 1900, a slightly larger amount per individual than during the corresponding month of the year 1899. The East London, Lambeth, Southwark and Vauxhall, and the West Middlesex companies supplied slightly less. With regard to the percentage of houses constantly supplied by the London water companies, the Chelsea and Grand Junction alone profess to give constant service throughout the whole of their district. The East London supplies 99 per cent. of its customers constantly, and this percentage is the same as it was a year ago. The Kent, Lambeth, and Southwark and Vauxhall companies do not give constant service in all cases nor has any improvement in this respect taken place in the case of any of these companies during the last year. The amount of constant service given in the case of the Kent company is still 94 per cent., the Southwark and Vauxhall 93 per cent., whilst the Lambeth company sti gives constant service to only 75 per cent. of its customers.

During the year some improvement has been made in the case of the New River company, which now gives constant service to 95 per cent. instead of 92 per cent. of its customers, an improvement of 3 per cent. The greatest amount of progress in this respect during the year has been made by the West Middlesex company which on July 31st last gave constant service to 97 per cent. of its customers, whereas on the corresponding date in the year 1899 constant service was given to only 89 per cent. This improvement is satisfactory. It seems strange that no less than 25 per cent. of the customers of the Lambeth Company should be content to receive water on the intermittent system. Any water consumer who feels aggrieved in the matter has legally the remedy in his own hands if he will only use it. Dr. T. E. Thorpe, the analyst appointed by the Local Government Board, gives an analysis of one specimen each of the water supplied by the metropolitan water companies. The analyst's report, we notice, is signed "pp. T. E. Thorpe, H. J. Helm." The analysis shows that the water drawn from the mains of the Lambeth Company contained the highest proportion of organic carbon. The water of the Lambeth and that of the Southwark and Vauxhall companies showed the deepest average tint of brown.

## RECURRENT LUXATION OF THE ULNAR NERVE.

THE *Boston Medical and Surgical Journal* of August 2nd contains an important paper on this rare condition by Dr. F. J. Cotton. Three original cases are recorded and the literature of the subject is exhaustively considered. Case 1.—A woman, aged 25 years, had much pain on using the arm after a fall on the elbow. A week after the accident the elbow was puffy and tender. A tender cord was felt in front of the inner condyle. On extension of the elbow it slipped back into the normal position of the ulnar nerve. Whenever the elbow was flexed to a right angle the luxation occurred and when it was extended reduction took place. An obtuse-angled splint was applied and a pad was placed over the internal condyle. After a fortnight there were little pain and less tendency to luxation. Only the pad and bandage were continued and light use of the elbow was permitted. The symptoms improved slowly and steadily, and the patient soon discontinued treatment. Four months later she could use the arm well, and complained only of occasional darting pains in the hands. On flexion of the elbow the nerve slipped only as far as the tip of the epicondyle. Case 2.—A girl, aged 11 years, fell on her elbow. Three days later she went to hospital with a slightly swollen elbow. Motion was slightly painful and there was spontaneous pain in the middle and ring fingers, but none along the distribution of the ulnar nerve. On flexion to 60° the nerve, which was abnormally tender, slipped a little in front of the epicondyle. An internal right-angled splint was applied. After three days the pain had disappeared and there were much less tenderness and perhaps slightly diminished range of luxation. The use of the splint was continued and massage was begun. Improvement was considerable, but luxation still occurred on flexion. Case 3.—A boy, aged 10 years, was seen three days after a fall on the elbow. There was a slight luxation of the nerve which did not pass beyond the tip of the epicondyle. The symptoms were local tenderness and pain on movement. The further history is not known. As early as 1851 Blattmann described a case of luxation of the ulnar nerve, but the first adequate accounts of recurring luxation are those of Lutz published in 1879 and of Zuckerkandl published in 1880. The cases form two groups, those for which no exciting cause is known and which may or may not be associated with symptoms, and the traumatic cases where there are almost invariably symptoms of greater or lesser severity. The trauma may be direct violence, muscular over-exertion, or simply habitual over-use of the elbow. In most cases, when a certain degree of flexion is reached the nerve moves inward to the tip of the epicondyle, and in the severer ones passes over it on to its anterior surface, only to return to its normal position on extension. Permanent luxation is very unusual. As to the symptoms of the non-traumatic or congenital form in one case there were marked weakness and considerable atrophy of the muscles supplied by the ulnar nerve, in a second case there were numbness and weakness sufficient to prevent work and to necessitate an operation, in a third there was fatigue on exertion, and in a fourth there were numbness and pain. In many cases symptoms beyond those arising from accidental pressure on the nerve are absent. As to the frequency of this form, Collinet on examining 500 patients found that in 13 the nerve was luxated on flexion, and in five of them on both sides. In the traumatic cases the symptoms (which are illustrated by the cases above described) subside more or less independently of treatment. In the non-traumatic cases the dislocation appears to be due to laxity or absence of the fibrous tissue which surrounds the nerve, and to the fact that the triceps spreads inwards on flexion of the elbow and pushes the nerve in front of it. In the traumatic cases some tearing of the fibrous tissues seems to occur either from muscular exertion or from the force of a blow. The treatment in these cases has been immobilisation with or without massage or operation to re-form the fibrous groove of the nerve. In some cases the fibrous tissues have been trimmed, the edge of the triceps has been hitched to the internal condyle, leaving the nerve beneath the bridge so formed, or a slip of fascia has been dissected up from the covering of the epitrochlear group of muscles and stitched to the triceps. These operations cured the luxation and such symptoms as depended on it, but in many cases conservative treatment gives quite as good results. Moreover, symptoms may be present, due to damage of the nerve, which cannot be benefited by operation.

## DANGEROUS GAS PENDANTS.

IF we do not go so far as to say that the "gas chandelier," or water-slide pendant as it is called, should be made illegal, we certainly think no prudent householder should put one of them into his house. It is never at any time by any twist of the imagination ornamental, it frequently occasions alarm, and in not a few instances it has been the cause of death. As everyone knows the principle of this "chandelier" is that of a water seal, which, of course, fails when there is no water in it. Few people remember to replace the water which easily evaporates in a warm atmosphere. Even supposing, however, that there is water in the sliding tube the chains supporting the weights which keep the pendant in position may easily get defective and thus the bracket may drop below the water seal and the gas be allowed to escape. This is probably what happened in the melancholy occurrence reported from Birmingham last week. It was shown that a water-slide pendant had become defective owing not to want of water in the tube but to the flimsy chain fittings. These defects accounted for the death of a man and very nearly for that of his wife. Both had retired to bed in good health, but before the morning they were poisoned with the escaping coal-gas which doubtless they had inhaled during most of the night. We have before recorded cases of this sort, and surely it is time that this clumsy contrivance known as the "chandelier" should be banished. It is a most dangerous fitting and quite unnecessary in view of the improved modern appliances which are now made for conveying gas from the supply-pipes to the burner. A good deal has been said of late against the increasing practice of carburetting gas, a method which raises the proportion of carbon monoxide

very considerably in illuminating gas. It is said that gas of satisfactory illuminating value could not be supplied without recourse to this plan, for not only are all kinds of coal more expensive than formerly, but the supply of the more bituminous varieties is distinctly running short. It must be remembered that coal-gas is poisonous under any circumstances, and that being so care must be enjoined in its use. But the fact that our present supply of coal-gas does contain much more carbon monoxide than was hitherto the case warrants more forcibly our argument in favour of the abandonment of the "chandelier."

## SIR GEORGE HARE PHILIPSON.

THE members of the medical profession in the north of England have decided to invite Sir George Hare Philipson to a complimentary dinner in celebration of his having received the honour of knighthood and in recognition of his services to the medical profession. The following committee has been formed to carry out the arrangements: Dr. G. H. Hume (chairman), Dr. D. Drummond, Mr. F. Page, Dr. R. S. Peart, Dr. W. C. Beatley, Dr. T. Beattie, Dr. J. Munro, Dr. J. Hedley, Dr. W. Robinson, Dr. J. Murphy, Mr. G. P. Elliott, and Professor T. Annandale. Honorary secretaries: Dr. W. Crump Beatley, 4, St. Mary's-terrace, and Dr. T. Beattie, 3, Ellison-place, Newcastle-upon-Tyne. The dinner will take place on Tuesday, Oct. 2nd, at 7 P.M.; tickets, £1 1s., including wines. Those desirous of being present are requested to apply to either of the secretaries before Sept. 22nd.

## THE TREATMENT OF ACUTE ALCOHOLISM BY LARGE DOSES OF DIGITALIS.

THAT acute alcoholism can be treated in robust and otherwise healthy subjects by large doses of digitalis with apparent success is well known, but the perils of the treatment are obvious and its value is doubtful. In the *Journal of the American Medical Association* of August 11th Dr. Henry P. Loomis of New York revives a discussion of the subject by detailing some cases. During the spring of the present year Dr. Loomis, while on duty as physician to the alcoholic wards of Bellevue Hospital, New York, used the tincture of digitalis in half-ounce doses in a series of ten cases of acute alcoholism. These were selected so as to include different classes of individuals—the strong and the robust, the weak and the anæmic, the young and the old. In the treatment of patients suffering with delirium tremens the routine practice was to give a half-ounce dose of the tincture of digitalis every four hours till three doses were taken. "If the patient became quiet and the delirium disappeared the remedy was stopped before the third dose. If not another series of three doses six hours apart was ordered. In the cases that showed the best results not more than three doses were necessary. The guide to the repetition of the dose was its narcotic effect." No marked dropping of the pulse was noted in any of the cases, but in the successful ones the pulse increased in force and became stronger, fuller, and more regular after the first dose. The cold, clammy perspiration disappeared, the skin became warmer, and the patient went to sleep. In three out of the ten cases treated the result was so pronounced and so quick that there seemed to be no question that it was entirely due to the effect of the digitalis. In some of the cases the remedy was a failure. Two cases died, one of these being complicated with acute articular rheumatism. From the experiences gained in the ten cases at Bellevue Hospital, as well as in six cases treated previously in the same way, the following conclusions are drawn by Dr. Loomis. The cases suitable for treatment with large doses of digitalis are the strong, the robust, and those in early adult life with no complications, and those with violent delirium. In such cases the results are exceptionally favourable. The patients become quiet and go to sleep with a certainty and promptness obtained by no other method. The remedy should not be adopted in the case of chronic alcoholic subjects, in those of middle or advanced life, or in those with anæmia and bad nutrition, as in such cases the remedy may be useless or even harmful. One fact which showed the marked benefit derived from the treatment was that when the patients recovered and awoke from their sleep they were in such an improved state that they were able to leave the hospital on the same day, whereas ordinarily there was a delay of two or three days before this was possible.

## ARE COPPER SALTS POISONOUS?

IN a paper upon this subject read before the British Association of Science at the Bradford meeting Dr. T. W. Hime sought to justify the use of copper salts for preserving the green colour of vegetables apparently on the ground that Nature herself placed copper in many of her products. Indeed, Dr. Hime asserted positively that there was no sufficient ground for the prohibition of the sale of coppered vegetables any more than for the prohibition of the innumerable kinds of fruits, vegetables, shell-fish, cereals, mineral waters, wines, and animal flesh which naturally contained the metal in some form. If the latter drastic arrangement were attempted, he added, absolute and general starvation would be the inevitable result, so widely was the natural presence of copper in articles of food extended. On these grounds Dr. Hime might justify arsenic as a useful food preservative, since it is now known to be a normal constituent of the body, but of course, like copper, in infinitesimal amount. We do not object to the plan of preserving the colour of peas by copper, but we do object to the consumer not being made plainly aware that such is the case with the provisions he consumes. Some people like their meat roasted, others do not care a tittle whether it be baked or gas-cooked; but it is clearly deception when a person is told that a piece of beef has been roasted which instead has been cooked in the gas-oven. Neither does Dr. Hime seem to pay special regard to the important question of personal idiosyncrasy. If the quality of our food-supply is to be State-protected with any degree of efficiency this is a point which must not be lost sight of, for in all the attempts to keep up the health of the community all sorts and conditions of men must be reckoned with. We hope to see very soon a statute which shall definitely control all methods of colouring and of preserving food.

## A CASE OF WERNICKE'S CONDUCTION-APHASIA WITH NECROPSY.

DR. HOWELL T. PERSHING has published in the July number of the *Journal of Nervous and Mental Diseases* a case illustrating the rare and interesting condition described by Wernicke as "conduction-aphasia." Dr. Pershing regards the present case as perhaps the most typical instance hitherto recorded of true conduction-aphasia. The case was that of a man, aged 45 years, of robust health, who was brought to hospital in an unconscious condition on Nov. 19th, 1897. The history of the patient was that two days before, while driving, he became unconscious and fell from his waggon into the bed of a small stream where he lay for about 36 hours before being found and removed to the hospital. On examination he was completely unconscious, the right arm and leg were rigid and tremulous, and the head and eyes showed slight conjugate deviation to the right. The pulse was normal, the respirations were 20 a minute and stertorous, the temperature was 99·5° F., and the head was free from signs of injury. A diagnosis was made of a vascular lesion (probably syphilitic thrombosis) in the left hemisphere and the patient was treated with iodide of

potassium and inunctions. In the course of a week consciousness completely returned, "but the man's talk was a mere jargon which he shouted in a loud voice. There was also some word-deafness; he generally failed to do what he was told, but responded readily when shown by a gesture. No paralysis could be detected. During the second week in the hospital the word-deafness disappeared and no sign of a cerebral lesion then remained except jargon-paraphasia and certain associated defects." Some weeks later he apparently understood any question that was asked him and would make an energetic attempt to answer it, but his talk was never intelligible. He could use the terms "Yes" and "No" accurately in response, "but on attempting to express himself at any length, although the first few words were often intelligible and apparently appropriate, he soon passed into a fluent but incomprehensible jargon in which only here and there a correct word could be heard. ..... He was entirely unable to name familiar objects. On being asked to read aloud from a newspaper ..... his reading was markedly paralexic; a few short words were correctly pronounced and the pronunciation of others bore an obvious resemblance to the correct sounds, but these were so mingled with unintelligible sounds that the whole conveyed no meaning to a listener. The simplest directions given in writing elicited no response. ..... He wrote his own name quite legibly, only putting an extra 's' on the end. He was absolutely unable to write anything else, either spontaneously or at dictation. ..... Acuity of vision was good, there was no hemianopia, he had a keen eye for all that went on about him, and often laughed at another patient whose appearance and actions were comical." Two months after his first attack he had a second attack (Jan. 23rd), during which he died. The necropsy revealed an oval spot of softening, 18 by eight millimetres, in the left cerebral hemisphere immediately above the fissure of Sylvius and two and a half inches (6 centimetres) behind its vertical branch. The softening extended an inch deep into the brain substance and probably destroyed communication between the first temporal and third frontal convolutions.

## LANCASHIRE ASYLUMS.

SOME interesting statements are made in a report just presented to the Lancashire Asylums Board by a deputation from that body appointed to visit the asylums on the continent and to make recommendations as to the building of a sixth Lancashire asylum. One fact mentioned is the serious increase in the number of patients of late years. In 1859 the total number was 1587, but a gradual increase has now brought the number to 8665. Before the end of next June it is hoped that a portion of the Winwick Asylum will be opened for 1000 patients, to be followed in June of the following year (1902) by the opening of the other portion of the building, also to accommodate 1000 cases. The cost of land, buildings, and furnishing will reach £400,000. The deputation, consisting of Alderman Jenkins of Salford, Dr. Cassidy, superintendent of the Lancashire Asylum, and Dr. Wiglesworth, superintendent of the Rainhill Asylum, visited asylums in Germany, Belgium, and France. They were struck with the large proportion of medical officers in the German as compared with the English asylums, being about one to 105 in the former and one to about 300 in the latter. They consider the English asylums to be under-officered to such an extent that there are difficulties as to the study of individual cases. They found also in the German asylums much more evidence of active scientific work than is usual in this country. They were favourably impressed with the "villa colony system" as they saw it in Germany and definitely recommend it for the projected new asylum, which they think should be entirely for epileptics and imbeciles, preference being given to those capable of a certain amount of work so that the beneficial effects of colony life may receive full scope. They see no necessity for a large central institution and recommend that no building should contain more than 50 patients, while the majority should have from 25 to 40. Also that the new asylum should accommodate 1000 patients with provision for extensions. They think that 250 acres would suffice but advise that 300 be acquired. There is every disposition to meet the requirements of the case, and no time will be lost in making the new asylums ready for patients, for there is great difficulty in finding accommodation for the new cases, for the four asylums now occupied have been "full and congested" for a long time. It would only be reasonable to look a little ahead and keep the accommodation somewhat in excess of present requirements, which position will scarcely be gained even when the sixth asylum is completed.

## A FRIEND OF SCIENCE.

THE education and research fund of Guy's Hospital Medical School has received from "A Friend of the Hospital" the sum of £5000, the interest of which is to be used to "increase and spread the knowledge of the means of preventing and treating disease." The friend of the hospital shows himself to be a true friend of science.

## PROPOSED SMALL-POX HOSPITAL AT BARRY.

So long as the English system of vaccination is, for the the great majority, vaccination in infancy only, so long must public health authorities be prepared for the occasional occurrence of epidemic of small-pox among the adult or adolescent population. Precautions to meet such epidemics are especially needful in the case of towns where many workmen are in close relation with each other through common employment, and at seaports where risk of introduction of small-pox is considerably greater than is the case of inland towns. Barry is a town to which these considerations specially apply, and it is satisfactory to find that the necessity of making isolation hospital provision for small-pox is there generally recognised. It appears, however, from local newspapers that the character of the proposed hospital is being made the subject of a warm, if not an acrimonious, dispute. Much opposition, in which some members of the profession have joined, is being made to the proposal of the town council to erect a permanent building at the cost of some £9000, under loan sanctioned by the Local Government Board. Such a hospital is objected to on the ground of expense, and it is urged that small-pox isolation will so seldom be needed that "temporary" provision is all that is necessary. We have sympathy with the movement to keep down the growing burden of local rates, but on the general ground of sanitary efficiency, and apart from local considerations of a particular case, we should certainly hold a scheme for erecting a permanent building as the more worthy of support. "Temporary" hospitals for small-pox are in many ways undesirable. Either they are "temporary" in the sense that everything is left to be done at the last moment in face of an epidemic—with what inadequate and objectionable results outbreaks such as those at Warrington and Gloucester have repeatedly shown—or satisfactory provision is made beforehand, as in a permanent hospital, the difference being that the buildings are of corrugated iron and not of brick or stone. In the latter case, even if the first cost were reduced by half, where is the economy to the ratepayer? Not at the beginning, for he will have to pay the whole cost of the hospital out of current rates and cannot spread it over a long period of years by loan. Later it is inevitable that considerable sums must be spent in keeping the temporary building in serviceable condition, and

finally, when it is past use there will be nothing to show for the expenditure and the whole affair must be begun again. As to the long periods for which it is said that the proposed hospital would be unused, we also have some doubt. There are epidemic diseases besides small-pox which from time to time tax all the resources of a district, and on such occasions even a liberal provision of beds at a hospital for ordinary infectious diseases often proves quite inadequate.

## OUR FRIENDS AND OUR FOES AMONGST MICROBES.

STERILISE, sterilise, would appear to be the teaching of bacteriology in regard to what we breathe, what we eat, and what we drink. But it is a moot question whether in the main life is best preserved by killing on all sides the ubiquitous microbe. Certain it is that some foods lose their important dietetic properties on being sterilised, and we have yet to learn whether there are not microbes in the air playing a rôle in the process of respiration. And if in air why not in food and drink, playing a rôle in the processes of digestion? Some illustration of the unsatisfactory state of our knowledge of these important questions was given in the first and third sections at the recent meeting of the Tenth International Congress of Hygiene and Demography in Paris. To quote a single example, engineers on the one hand, during the discussion of certain papers on the question Should all drinking water be sterilised? rose and challenged the bacteriologists to say once and for all whether or not all bacteria were injurious. The conflicting opinions contained in the answers of the different bacteriologists left the interrogators in doubt, but certainly justified their question. One speaker put the position very pertinently when he reminded his audience that, when Simon de Montfort during the Crusades had captured a town, and was asked the question as to what should be done as all the inhabitants were not heretics, but some of them good Christians, he replied: "Massacre them all and God will recognise His own." In the present state of our knowledge this seems exactly to define our attitude in regard to the treatment of organic life existing in air, food, and water. The fact that micro-organisms are being employed now with great profit in many industrial pursuits, and more important still in the satisfactory disposal of offensive human excreta, only adds perplexity to the question how far sterilisation can safely go. Doubtless it will be shown that in order to prevent disease set up by organisms we must pick out a means of killing only that species which is pathogenic. Failing this we are probably safest in adopting the plan of Simon de Montfort. We burn the wheat as well as the tares because it must be confessed for the present that we know no better; we cannot exactly differentiate the good from the bad.

## ANTI-VIVISECTIONISTS AT CARDIFF.

ALTHOUGH the public health laboratory organised by the borough of Cardiff and the county of Glamorgan has been established only about a year it has already done good work and has thoroughly justified its existence. The possession of a licence for the performance of experiments upon animals has, however, drawn upon it the opposition of a section of the inhabitants of the town and neighbourhood, and at a meeting held at Cardiff last week which was called at the instance of the British Union for the Abolition of Vivisection the following resolution was passed:—"That this meeting pledges itself to demand and exert itself to obtain the withdrawal of all licences for the protection of vivisection in Cardiff." We should hardly have deemed it necessary to direct attention to this gathering but for the extraordinary manner in which the meeting was conducted. Lady Windsor occupied the chair and at the outset invited those present to listen to the speeches about to be made with open minds, and it almost appeared as though for once there was to be at an anti-vivisection meeting a fair and square discussion. This anticipation was unhappily falsified by the event, for after Lord Tredegar and others had spoken in favour of the resolution, Mr. T. Garrett Horder asked to be allowed to make a few remarks but was promptly told that the meeting was called to forward the aims of the society for abolishing vivisection and not to hear any general discussion. With a meeting in such an exclusive humour as this it is not at all surprising that the suggestion of a reverend gentleman was accepted with enthusiasm when he proposed that ministers of religion be asked to bring to the notice of their congregations the petition to the Home Secretary asking that the Cardiff licences should be revoked. According to the local newspaper reports the Mayor of Cardiff was among the audience and Lord Tredegar is a prominent member of the Monmouthshire County Council. These gentlemen, it is to be hoped, will urge the claims of the petition before the important public bodies upon which they sit. County councils and corporations are in the habit of discussing matters brought before them and the British Union for the Abolition of Vivisection might gain some information from the debates.

THE representative board of the British Dental Association desire to remind members of the medical profession engaged in researches for the advancement of dental surgery that they are prepared to receive applications for grants in aid of such research. Applications for sums to be granted at the next annual meeting must be made on the printed forms to be obtained of the honorary secretary at the office of the Association, 40, Leicester-square, London, on or before Dec. 31st next.

THE first session of the Medical Faculty of the University of Birmingham will open on Monday, Oct. 1st, when an address will be delivered by Professor B. C. A. Windle, M.A., M.D. Dub., Dean of the Medical Faculty and Professor of Anatomy in the University.

A TELEGRAM from Sir H. A. Blake, the Governor of Hong-Kong, to Mr. Chamberlain, received at the Colonial Office on Sept. 10th, 1900, states that four cases of bubonic plague, with four deaths, occurred last week.

THE death is announced, at Constantinople on Sept. 2nd, of Mr. Richard Sarell, M.D. Edin., M.R.C.P. Lond., one of the best known surgeons in the Levant. He was aged 70 years.

# THE WAR IN SOUTH AFRICA.

THE war is moving to its inevitable end and with it one of the most difficult and hard-fought campaigns in which this country has ever been engaged will take its place in military history. Events have of late been proceeding with something like dramatic rapidity. Ex-President Kruger is reported to have arrived at Lorenzo Marques and the Boer forces are retreating and crumbling away, so that things must be nearing an end. Lord Roberts is apparently of that opinion, for he has gone to Pretoria, to meet the South African Commission, which arrived there on Sept. 8th. The commission has already examined Sir William Thompson, Dr. Kendal Franks, and Lord Roberts. The commander-in-chief's evidence, as reported in the *Times*, dealt at length with the rapidity of his advance. Due supplies of food and ammunition had to be provided, and as this was the first consideration in war the transport of other articles was necessarily restricted. There is no need to enter into any discussion of a controversial character

at the present moment in regard to matters medical; it would, indeed, be futile to do so until all the facts are known. We shall learn in due time how far it would have been possible to have foreseen and prevented the occurrences which took place at Paardeberg and Bloemfontein by the timely provision of sanitary arrangements. Unfortunately it is one of the contingencies of war that mobility—especially in fighting with ubiquitous Boers—is essential to success and that an enemy will not suspend its military operations until the other side is ready to begin. Were it otherwise there would be little or no difficulty in perfecting all the necessary hygienic arrangements.

Meanwhile, we are glad to say that the British troops are healthy and in excellent fettle and that the war is being prosecuted with vigour. So long, however, as the Boer generals can muster any forces in the field we may expect occasional raids and surprises and attempts at cutting lines of communication. An army of occupation may have a lively time of it at first, but these attempts will gradually decrease until they cease altogether.

---

### THE TREATMENT OF PRISONERS BY THE BOERS.

The War Office issued on Sept. 12th despatches giving an account of the evidence before, and the findings of the Court of Inquiry ordered by Lord Roberts to investigate the treatment of the British prisoners of war at Pretoria. Lord Roberts in his comment on the report states that the officers were fairly well treated, but that the men were badly treated. The treatment of the prisoners belonging to Colonial corps raised in South Africa Lord Roberts considers to have been opposed to the usages of civilised warfare in that they were treated as criminals, and the same remark applies to British subjects resident in the Transvaal who were treated in a like manner because they refused to take the oath of allegiance to the Republic. Lord Roberts also considers that the inhuman treatment of the sick prisoners throws the greatest discredit on the authorities at Presoria, since they must have known that proper hospital accommodation and equipment had not been provided, that suitable food and medical comforts were not forthcoming, and that the supply of medicines and medical comforts was wholly inadequate. The commander-in-chief's conclusions form a severe indictment of the Republics, but the documents which are included in the despatches, and to which we shall make further reference, appear to warrant the conclusions.

---

### SOME NOTES ON THE CAMPAIGN IN AUGUST.

BY ALFRED D. FRIPP, M.S., F.R.C.S.,
SENIOR SURGEON TO THE IMPERIAL YEOMANRY HOSPITAL.

This is a windy month, therefore there is much dust and discomfort; also it is so cold at night that occasionally the water freezes in the vessels inside the tents. There is a welcome lull in the work which the hospitals are called upon to do.

There are no fewer than four Yeomanry Hospitals at work in South Africa now and before very long there will be a fifth. This base hospital, which has had accommodation for 1000 beds since July 1st, has detached part of its staff, including Mr. Turner as medical officer and one of the surgeon's dressers and three of the nursing sisters, to take over the management of the hospital at Maitland camp with 25 beds, and the establishment will shortly be increased in view of the remassing there of the Yeomanry prior to their departure for England. The Yeomanry Field Hospital is established at Pretoria and has similarly detached part of its staff, including Mr. Openshaw, to manage a hospital which has been opened in one of the buildings in that town and which, according to a telegram from Surgeon-General Wilson, "is doing excellent work." Lastly, the staff of the new branch hospital (intended originally for Pretoria, then allotted to Johannesburg, and now re-allotted to Pretoria) have been lodging with us since they arrived in batches on July 20th and 27th. To-day the first half go forwards and will be picked up at Bloemfontein by Surgeon-Major C. R. Kilkelly, who will escort them to Pretoria, where Dr. Barclay Black is already at work with one of our own sergeant-majors scheming out the sanitation on exactly the same lines as have proved so successful under their guidance here. There will eventually be accommodation for 400 beds in this Pretoria branch. The staff consists of 40 nursing sisters (for whom sleeping-room has been found here by emptying one of the huts of the patients), nine doctors, and 80 orderlies (who have been put up in some of our tents). As it is over four weeks since we took in a trainload of fresh cases work throughout this hospital is very light. Indeed, if it were not for the regular daily arrival of small batches of Yeomanry we should not even be, as we are, half full. There are not 10 serious cases in the entire hospital, and we are just completing our fourth consecutive week without a death, so that our own 45 sisters have no more work than they can easily accomplish and as there is nothing for the 40 visitors to do time hangs heavily upon their hands. A few of them have taken the work of our original sisters while the latter have gone away for a few days' change—generally to those two very popular places, Kimberley and Mafeking. Similarly the opportunity offered by the presence of so many extra orderlies in our midst has been seized for giving a little well-earned rest to our own men who have been kept hard at work without a break of any sort since their arrival here on March 1st, and also for getting a few odd jobs done about the camp, notably the making of a good road to the cemetery which lies a quarter of a mile away and which now contains 59 graves. Had these extra sisters and orderlies been lodging with us three, or even two, months ago there would have been plenty of work to occupy them in the wards as reinforcements to our own staff, but in those days it would have been a very difficult thing for us to house them.

It was a great piece of good fortune that the disbanding of the Portland Hospital should have come, if it had to come at all, just in time for Surgeon-Major Kilkelly, who has been in charge ever since its mobilisation last autumn and who has made such a great success of it, to transfer his able services to the new Yeomanry Branch Hospital. There are many points in the running of a mixed civilian and military hospital which call for the possession of exceptional qualities by the man who is selected to act as the commandant, and which, even when the man has those qualities, must present less difficulty if he has also previous experience of the special needs of these mixed establishments. This is the first war of modern times in which they have played a really important part. By voluntary civilian effort the necessary *personnel* and material have been sent out from the old country alone (exclusive of the field hospitals which accompanied the colonial corps) for equipping roughly 2000 beds. 1000 of these are to be found in the Imperial Yeomanry Hospitals, and the other 1000 are distributed thus: 300 in the Glasgow Hospital, 100 each in the Portland Hospital, the Langman Hospital, the Edinburgh Hospital, the Irish Hospital, and the Welsh Hospital, 200 (I think) in the Princess Christian Hospital recently presented by Mr. Moseley to the Natal Government, and 25 in the Van Alen section of a field hospital. As a matter of fact each of these civilian-military hospitals had during the recent time of stress to temporarily increase its accommodation by 50 per cent., so that in one way and another the total reinforcements presented to the Royal Army Medical Corps authorities by voluntary effort amount to the large number of 3000 beds fully equipped and staffed. That Surgeon-Major Kilkelly possesses the qualities necessary for the head of one of these hospitals is proved by the great success which has attended his management of the Portland Hospital, and as that hospital was at work nearly three months before this, which was the second civilian hospital to arrive in South Africa, he has had more experience in the matter than any other officer. The Imperial Yeomanry Hospital, however, like the Portland Hospital, has been extremely fortunate in its commandant. Lieutenant-Colonel A. T. Sloggett is just the man for the job, the right man in the right place. No two officers could possibly have turned to better account the magnificent chances offered by the way in which the respective committees of these two institutions in London launched their undertakings. They sent out a splendid equipment and staff and having chosen their senior officers they trusted them and gave them a free hand and backed them up strongly on the few occasions when want of support might have perpetuated or might have bred difficulties. Their reward for having followed this sensible line of policy is found in the success which has resulted from it—a success which is marked enough to have caused a little quite excusable jealousy on the part of others who have not had equally good chances. I say "quite excusable" because it must be very annoying to those in authority in another hospital to hear the place for which they have laboured just as hard and

perhaps harder than their more fortunate professional brothers elsewhere perpetually being compared unfavourably by the patients and others with another institution. Indeed, there must be many officers in the Royal Army Medical Corps who envy Colonel Sloggett and Surgeon-Major Kilkelly their good luck in getting their present berths under a master who can be relied upon to grant every sensible request and to grant it at once and with evident satisfaction that it was made, and it must be a new and very pleasant experience to these two officers to find themselves working for such a master.

If, however, our Yeomanry Hospital has had the good fortune to be enabled to spread a comparatively rich table, many are the less fortunately-placed establishments which have benefited by the picking up of crumbs from it. At one time and another huge quantities of our stores, and of our equipment too, have gone astray. We hear that some packages have found their way back to England without redirection. The vast majority of those which we have lost have found in other camps out here a home which is rendered permanent by the generally understood, though unwritten, law of campaigning which ordains that any commandant has an indisputable right to stick to anything which falls into his hands. If only our packages chanced to fall into camps that wanted them more than we did I do not think anybody would grudge them, but a not inconsiderable quantity of our goods has been pilfered. When the entire packing-case fails to arrive it is seldom possible to ascertain what has become of it. The store-keeper who is new to his job or to the ways of the country worries a bit the first few times it happens, but after a short experience he thinks little and says less if out of a consignment of, say, six or eight dozen cases of wine or other attractive-looking goods only two or three are missing. Not seldom a whole truckful misses its right destination, but it finds another and with luck it may be brought back whole or in part. Occasionally a large portion of a train is consigned to one place but arrives at another. That happened to us once. As a general principle, however, the larger the mistake the more likely it is to be retrieved. It is the frequency of acts of really petty larceny which has most worried individuals and institutions. The quantity of "comforts" which have been stolen *en route* from friends at home must by this, the tenth month of the war, amount to something enormous. It is really no exaggeration to say that, after six months' experience, one is more surprised at receiving from England undamaged the box of cigarettes or other inviting-looking parcel which friends at home are so good in sending than one is to get the empty or half-empty case or the letter only which tells of its despatch. Several friends most kindly took to sending me a small parcel of tobacco each week. The result of the experiment was so disastrous that I had to write and advise them to stop it. Within the last three weeks three separate consignments of cigarettes, 25,000 in each, for distribution to the patients have been despatched to us from Cape Town. Only one of the three arrived at all and that had been opened, so that out of 75,000 cigarettes 24,000 reached the patients. The leakage is not by any means confined to the railway journey. I know of instances where the depredation was traced to the docks in Cape Town, and of one case in which it was clearly proved to have occurred before the parcel was put into a packing-case in England.

Surgically speaking there has been very little to do here of late, so little indeed that Mr. Raymond Johnson has gone home, for he felt that as things are now there is a greater call for him to be in his place at University College Hospital for the beginning of the winter session than for him to longer await here the often-expected downfall of Christian De Wet. The general impression is that as soon as that very able leader is wiped out Botha will quickly surrender, and that it is only the point of honour which makes the latter, as commander-in-chief, hold out so long as one of his subordinates keeps the field. Now that Colonel Sloggett has got back from Pretoria I am going to start at once on a short tour in Natal and unless any fresh rush of surgery should occur in the meantime I, too, hope to get home before Oct. 1st. At the present time there literally is not a case among our 519 patients which is not doing well or which needs more than a trivial operation, and even if there should by ill-fortune be a fresh and even a heavy access of surgical patients it is very unlikely that any of them would be brought down here. So very many hospitals are now established hundreds of miles nearer the front and all of them are, as we are, half empty, that there are vacant beds enough to easily accommodate 2000 or 3000 wounded without bringing any of them south of the Orange river, and now that the days of frontal attacks are over it is extremely improbable that anything approaching that number will have to be provided for. From the point of view of sickness, however, this indefinite prolongation of the war is becoming a serious matter. Apart from the comparatively light but still considerable weekly roll we are already within six short weeks of the end of September, when, as those with local experience warn us, there will be a recrudescence of enteric fever.

The Medical Inquiry Commission is due in Cape Town on August 21st, but whether they will first go to Natal, as is supposed, or spend a few days sifting matters in Cape Town before working up country to Pretoria by rail remains to be seen. It is said that they will cover all the ground and sail again within a month, but I do not think that it is possible. All signs of things as they were during the time of stress have disappeared, so that unless there is another terrible wave of enteric fever they will see nothing but apple-pie order throughout the hospitals. Everybody without exception, as far as my experience goes, is delighted at the addition to the Commission of those two representatives of administration and railway experience, for there is a very general consensus of opinion that the question of transport forms one of the chief roots of the difficulties under which the Royal Army Medical Corps laboured.

I said that there had not been much surgery to do in this hospital lately. As a matter of fact, from the middle of July to the middle of August there were 31 operations in the theatre, against 80 from the middle of June to the middle of July. These figures do not include the many small procedures carried out under nitrous oxide, such as opening abscesses, moving stiff joints, and extraction of teeth; for the latter alone there are two or three applicants every day. The nitrous oxide and the oxygen, of which we brought a large number of cylinders from England, have been most useful, and similarly we have had no cause to regret the bringing out of many other articles of equipment which, when they were proposed, evoked the adverse criticism of authority. One trembles to think what the hospital would have been like if it had not come equipped with its own laundry plant and steam steriliser at a cost of over £1200; nor would we for a good deal have lost the services of our masseur (he has recently got his Russian bath into working order, getting the steam from the laundry, and a most excellent and useful institution it has proved), or of our machine for making soda-water. It is much to have this manufacture under the supervision of a medical officer, for none of the soda-water procurable out here is free from the suspicion of being made from infected water. To turn out 40 dozen bottles, which is our maximum daily consumption, only takes the machine a few hours, so four months ago we made an offer in the right quarter to run the machine for the rest of the 24 hours for the benefit of the many other institutions which would be glad to have a reliable supply. The idea was voted a capital one by the head official concerned, and he said that he would provide the necessary syphons and make arrangements for the distribution. We at once made arrangements for the requisite increase in our supply of cylinders of $CO_2$, but we have heard nothing more about the matter. Presumably the head official had more important matters to occupy his time and attention than the substitution of a supply of soda water at cost price and reliable in both quantity and quality for the thoroughly unreliable article which some of the hospitals and messes are able to get if they can pay the enormous price which is asked for it. That, however, is one of the objections to the present organisation—there is so little delegation of power over details that an intended change has to be of supreme importance to stand any but a poor chance of being effected soon enough to be of use. Nor, again, could we possibly have properly nursed the 700 patients in one ward at the time of stress if we had bowed down to the official regulation which at that time limited the number of nursing sisters we had a right to bring to nine. Our committee in London braved the warnings, and the gibes too, of those whose business it was to know, but who evidently did not know, what infinite benefit is conferred upon the sick and at what infinitesimal inconvenience to the administrative department of a large hospital by the presence in it of a body of really competent nurses sufficiently large in numbers to actually nurse the grave cases. "They will only be tumbling over one another's

skirts and getting in one another's and everybody else's way," "They will only increase the trouble of administration and quarrel with the orderlies and grumble at the roughness of their food and accommodation," "Experience will soon teach you that a military hospital is a very different thing from a civil hospital, most of the patients are up and about and are only bored by the presence of a woman"—these are a few of the criticisms by which it was sought to throw cold water upon the pioneer effort of our committee to increase the numbers of the nursing sisters on the staff. 39 came instead of nine, but none of the prognostications ever came true; indeed, the entire male and female staff of the hospital has been a "happy family" ever since the start. Despite the criticisms and explanations which have raged around Mr. Treves's utterance with regard to women in South Africa I have not yet seen any statement in print which conveys any adequate idea of the magnitude and excellence of the work done by the nursing sisters in the war. It is only since March that their numbers have been brought up to anything like sufficiency, but they were here in time for the typhoid epidemic. It is true that ours were an altogether exceptionally well qualified lot of nurses, but they were such a success that we sent home for 10 more and these arrived just in time to save the original ones from breaking down in the weeks of stress from enteric fever. Nor have we even in lighter times found our numbers any too many to enable us to carry through the plan—on which I believe this was the earliest military hospital to work in South Africa—of having separate shifts of nurses for day and night work exactly as in a London hospital. Most fortunately not a single one of our nurses has contracted either enteric fever or scarlet fever, but surely the very fact that a considerable number of orderlies have got themselves infected looks as if the nursing sisters must have a much better appreciation of the value of cleanliness and the means to be adopted to prevent the spread of infection—or in other words that they must be much safer attendants upon the uninfected patients in the wards. I do not attempt to speak about field hospitals, for I have no experience of them, but I venture to express the hope that among the good things which will result from this war will be the establishment for all future time of a boon of inestimable value—that of having in every non-mobile military hospital a staff of really *well-qualified* (not merely "well-trained") nursing sisters in the proportion of somewhere between one to 10 and one to 20 of the patients. One nurse to every 10 hospital beds will be about the right proportion if in the future the principle of convalescent camps is confirmed, as I hope it will be. I think that this principle might be applied in times of peace as well as on active service and in framing the scheme a more convenient, if not a larger, application of the principle might be made than has been the case in this campaign. I believe that it would be found to work well if a convalescent camp was attached to each non-mobile military hospital.

Deelfontein.

## MEDICAL NOTES FROM PRETORIA.

(FROM OUR TRAVELLING CORRESPONDENT.)

I arrived in Pretoria on the morning of August 11th, after a peaceful and uneventful journey from Bloemfontein. Pretoria is a much handsomer town than the capital of the Orange River Colony; its streets are wider, its shops are larger and more numerous, and its general aspect is more bustling and business-like. The surrounding hills protect the town from wind, and the climate on the whole is milder and more relaxing than that of Bloemfontein and its neighbourhood. The general health of the troops at Pretoria is excellent. There are very few surgical cases in the hospitals and of the medical cases only one-third are returned as being of enteric fever, and this disease has never assumed an epidemic form. The total number in hospital at the present moment is only a little over 1000, while there is accommodation for some 2400.

The largest and most prominent building in the town, the Palace of Justice, has been converted into a marvellously complete military hospital of some 500 (to be exact, 493) beds, known as the "Law Courts Hospital." This magnificent building occupies one side of the Market Square and is made up of a basement storey used as store-rooms and over this a large central hall lighted from the roof. This hall is surrounded by galleries from which and from the hall itself two storeys of rooms of varying sizes open off. The hall has been converted into a huge ward of 72 beds known as the "Victoria Ward." Behind this and opening out of it are three large wards of 20 beds each; while doors at the sides and front lead into smaller wards, an x-ray room, operating theatre, offices, &c. Two lavatories, a large bathroom, and two ablution rooms are also on the ground floor. Doors from the gallery encircling the hall lead into the first-floor wards which are 20 in number and contain beds varying from eight to 12, and to three lavatories, day-rooms, and a dining-room for sick officers. The wards are bright and cheery, and, with the exception of the large 20-bed wards on the ground floor, well ventilated. The inefficient ventilation of these wards, owing to their being shut in by the wings, and the absence of ablution rooms on the first floor, were the only serious defects which I noticed. Two wings running back on either side of the large ground-floor wards contain a number of small rooms used for the reception of special cases and they unfortunately shut out a good deal of air and light from the large wards. The whole building is lighted by electricity. In the open space behind the hospital proper is a large corrugated iron kitchen, with scullery, &c. The waste water from the kitchen runs into an open sluice fed by a spring. This is the universal system of disposal of waste water in Pretoria. The pail system is employed for the removal of excreta, which are treated with creolin or crude carbolic acid, mixed with ashes and removed four times daily by the municipality. The whole hospital is under the management and superintendence of Captain W. T. Mould, R.A.M.C., while the *personnel* of the Irish Hospital forms the nucleus of the medical staff and nursing staff. There are in all nine surgeons, 130 non-commissioned officers and men, and 22 nursing sisters. Sir William Thompson, chief surgeon, kindly showed me round the various wards, which were almost entirely occupied by medical cases, mild enteric fever, diarrhœa, and dysentery predominating. The few surgical cases were mostly penetrating wounds of the extremities and were devoid of points of special interest.

Other buildings in the town—No. 1 Model School and No. 2 Model School, the Girls' School, and Bourke Hospital—accommodate 400 patients. All are completely equipped and nothing is wanting to the comfort of the inmates. The large Artillery Barracks were found unsuitable for hospital requirements and the buildings are employed by the principal medical officer for the reception of Royal Army Medical Corps details. No. 2 General Hospital, which is a marquee hospital containing 600 beds, occupies an excellent site about two miles to the north-east of the town, with a special siding. It is of the usual type which has been so frequently described in these columns and is completely equipped in every way. Near it are the Langman Hospital and the Welsh Hospital, containing 150 beds each. These also are marquee hospitals. The former is ready and is receiving patients and the latter will open in a few days.

Surgeon-Major C. R. Kilkelly, the military commandant, and Mr. Hamilton, the treasurer of the new Yeomanry General Hospital, are already in Pretoria and are working with their accustomed energy. They have secured a charming site on a gentle slope about a mile from the Market Square, in the grounds of a large country house (Mr. Beckett's). The house itself has been placed at their disposal and will accommodate 60 patients; the remaining 440 will be in marquees pitched around the house. Mr. Langman Brown and 42 nurses are daily expected from Bloemfontein, and there is every reason to believe that the hospital will be quite ready in a few days.

A very important little adjunct to the military medical system in the shape of a small "rest hospital" of 12 beds at the railway-station has been established by Colonel W. L. Gubbins, R.A.M.C., the principal medical officer of Pretoria. Patients arriving unexpectedly or late at night are taken in here until the ambulances can be called up to transfer them to the hospitals. I am much indebted to Colonel Gubbins for his courtesy in explaining the general hospital system here and for showing me over the rest hospital.

Pretoria, August 12th.

THE MIDDLESEX HOSPITAL.—The treasurers have received a donation of 1000 guineas from Miss Wicksteed to endow a bed in perpetuity in the cancer wards for female patients.

# THE PLAGUE IN GLASGOW.

Two more cases of plague have occurred since the publication of our last article, while a case which was then described as doubtful has declared itself to be the veritable malady. The total of cases therefore now reaches 16. A few such additional cases were to be expected when we recollect the history of the outbreak, an important feature in which was the fact that a full week elapsed between the sickening of the members of the Malloy family, presumably after attendance at the Bogan wake, and the recognition of their condition as infectious. During that interval free intercourse between the sick persons and their friends and sympathisers took place, and it was almost certain that the spread of the disease would not declare its limitations immediately. One exceedingly gratifying fact must be chronicled the new cases can all be traced to the originally infected area, and no spread has taken place to other parts of the town, although suspected cases among the 114 now under observation have been brought from other quarters. A suspected case occurring outside the infected area turned out not to be plague.

Every day that the spread of the disease remains thus limited is of immense value to Glasgow, for if no more foci of the disease are established the city may look forward in a very short time to being rid of the invasion. And to the commerce and shipping of Glasgow this is a matter of enormous importance. For at foreign ports ships arriving from Glasgow are being, and will be, placed in quarantine for varying periods. The danger to shipping from the present outbreak of plague may be infinitesimal, but foreign ports know of the outbreak only and not of the circumstances. Also quarantine is quite recognised by Great Britain as an obsolete and ill-judged way of arresting the spread of disease, but it is the orthodox method in the opinion of many nations with whom we trade. The detention in some cases will probably amount to a fortnight, and what this means when an expensive modern steamer is in question would surprise those who have never thought of the matter. Exports are ceasing, and will continue to cease, from Glasgow until the port has a clean bill of health, so that the stimulus to the inhabitants to help in every way to get rid of the plague is a very acute one.

The Borough Commissioners of Partick, Govan, and Kirkintilloch all held meetings at the beginning of the week, when it became clear that those responsible for the public health of the people in the neighbourhood of Glasgow are not giving way in the least to plague scare. At the meeting of the Govan Commissioners, Commissioner Fortune, referring to the fact that plague had actually occurred in the burgh, said that "it was well once in a while to have a scare such as they had had because it made many of the people more cleanly." He deprecated an exaggeration of the seriousness of the outbreak and detailed the precautions taken by the authorities in behalf of the public health. Bailie Smith at the same meeting carried his courageous contempt for plague a little further. He seems to have said that "in the opinion of the man in the street the medical men seemed to have lost their heads over the plague business. He thought the doctors might be suiting the purpose of the community if they made less fuss about the disease. There could not be any possibility of the plague raging to the extent it did some 200 or 300 years ago, chiefly on account of the great strides in sanitation." Bailie Smith is correct in thinking that modern sanitation is a check on plague, but he is very incorrect in thinking that it is the proper course for medical men, out of deference to the trade of a place, to neglect any precaution whatever for the complete stamping out of a terrible disease. If Dr. Chalmers and his able coadjutors had "made less fuss about the plague"—in other words, had not strained every nerve to suppress it immediately—the consequences might, and probably would, have been appalling. Fortunately Dr. Barras, the medical officer of health of Govan, while no alarmist, has not followed the line recommended by Bailie Smith, but has kept himself prepared to deal with any possible outbreak drastically.

At a special meeting of the Partick Commissioners a communication was read from the Local Government Board of Scotland suggesting the application of the Infectious Diseases (Notification) Act to plague. Accordingly the following resolution was passed, viz.:—

The Commissioners, as the local authority for the burgh under the Infectious Diseases (Notification) Act, 1889, declare, in terms of Section 7, Sub-section 6, of said Act, that emergency arises in consequence of the existence within the city of Glasgow of certain cases of plague, and therefore order that said Act shall in the district of the said local authority apply to "plague," and that for the period from the expiration of one week from the date of the advertisement to be made in terms of said Act till Sept. 3rd, 1901.

This resolution is published in the local papers and handbills have been issued throughout the burgh to the same effect. The Commissioners in remitting to the Sanitary and Sewers Committee power to take such measures as they might consider necessary specially authorised the temporary appointment of a medical man to inspect the whole burgh, beginning with the south side of it, and instructed the medical officer to get a supply of plague serum for inoculation where deemed advisable. The Convener and ex-Provost Caird were appointed along with the medical officer and sanitary inspector to arrange with the medical and sanitary officials of the city as to any measures that they might consider it advisable to adopt. Dr. J. Paterson, the medical officer of health of Partick, reported that he had engaged Dr. Kirkwood of Partick to make house-to-house visitations six days a week, and he had been at the work of inspection since Sept. 6th. The sanitary staff had also paid many visits to houses in the first ward with the object of enforcing cleanliness. An entire ward was in reserve at Knightswood Hospital for the treatment of any cases that might occur. On the whole the condition of the houses visited was good.

At Kirkintilloch, seven miles from Glasgow, at a monthly meeting of the burgh commissioners held on Monday last, Dr. W. Whitelaw submitted a brief report upon plague in which while admitting the bad pre-eminence of Kirkintilloch in cholera visitation he urged refrain from panic. And from other places in the neighbourhood the same story comes. The authorities, while neglecting no precautions, are resolved not to magnify the evils. This is the right spirit—it is the spirit which has made the Metropolitan Asylums Board prepare to receive plague patients in London, while at most of the large British ports the sanitary authorities are on the alert watching for the disease.

The rigorous cleansing of premises from which contacts have been removed, the emptying and limewashing of ashpits, the hosing of courts and the destruction of rats goes on apace in Glasgow. Many rats have been trapped in Rose-street and Thistle-street, Crown-street and Rutherglen-road during the past ten days, and after bacteriological examination were cremated. We are informed that none of the rats have so far been found to be infected. We publish additional notes from Dr. J. Brownlee and Dr. J. Campbell McClure as to the

### CLINICAL ASPECTS OF CASES OF PLAGUE UNDER TREATMENT.

(3) William Malloy, aged three years, 57, Thistle-street, Glasgow, was admitted to the Belvidere Hospital on August 25th. This child, who is the son of Mrs. Malloy, whose case was given in full last week, is stated by his mother to have become ill on August 21st. His symptoms appear to have been very slight. They consisted solely of slight pain in the abdomen and general malaise. On admission the temperature was 99·6° F., the pulse was 106, and the respirations were 22. The child's expression was dull and the face was very pale. There was a markedly enlarged gland in the submental region of about the size of a large marble. This gland seemed to be hard and adherent and the skin above it was slightly red. This gland, the mother distinctly stated, was not present prior to this illness. The glands in the axillæ, neck, and groins were palpable but were not markedly enlarged. Those in the right groin were the most obvious. Nothing noteworthy was detected in either lungs, heart, liver, or spleen. On August 26th the temperature reached 100·6° but without any aggravation of the symptoms; since then the temperature had been normal and the child fairly well. The submental gland above noted had decreased steadily in size till at the end of 10 days it was barely perceptible. No bacteriological examination was made in this case.

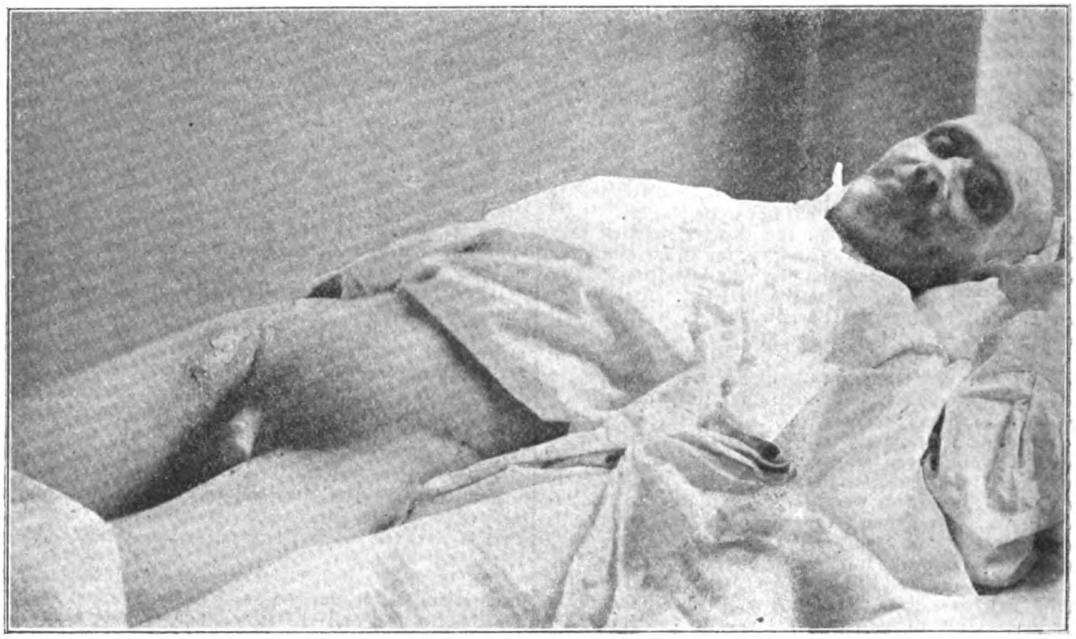
(4) James Bogan, aged 60 years, 71, Rose-street, was admitted to hospital on August 23th, his case being certified as enteric fever. The patient's grandchild and wife died on August 7th and August 9th respectively from a disease certified as "zymotic enteritis," but their symptoms were high fever and delirium of a nature not usually associated

with that disease. The patient sickened on August 15th, on which date he was suddenly seized with shivering, nausea, and vomiting associated with severe headache and slight abdominal pain. The symptoms from their onset were so severe as to make him take to bed, where he remained till his removal to hospital. From August 25th he suffered from diarrhœa and for the 24 hours preceding admission he was delirious.

*On admission* the patient's face was seen to have the same dull, heavy, and yet anxious look as described in detailing last week the case of Patrick Malloy. The pupils were moderately dilated and the conjunctivæ were slightly injected. The tongue was coated with a thick greyish fur in the centre, while the edges were moist and clean. There was no congestion of the fauces. The skin presented the same mottling noted before in Patrick Malloy, with the difference that over the abdomen it was much more profuse. In the right groin was a very large tense red and œdematous swelling occupying the situation of the verticle group of glands (Fig. 1). This swelling was exquisitely tender and the tissues surrounding it were so infiltrated as to make the appreciation of individual glands by palpation impossible. The lymphatic glands above Poupart's ligament were also palpable and slightly tender, while the skin over the right iliac region, though not reddened, was distinctly œdematous. Elsewhere the lymphatic glands were not palpable. The temperature was 102·8° F., the pulse was soft and weak and numbered 72, while the respirations were at the rate of 24 per minute. The abdomen was slightly distended and rather tense. Nothing noteworthy was detected in the heart and lungs and the spleen and liver were not enlarged.

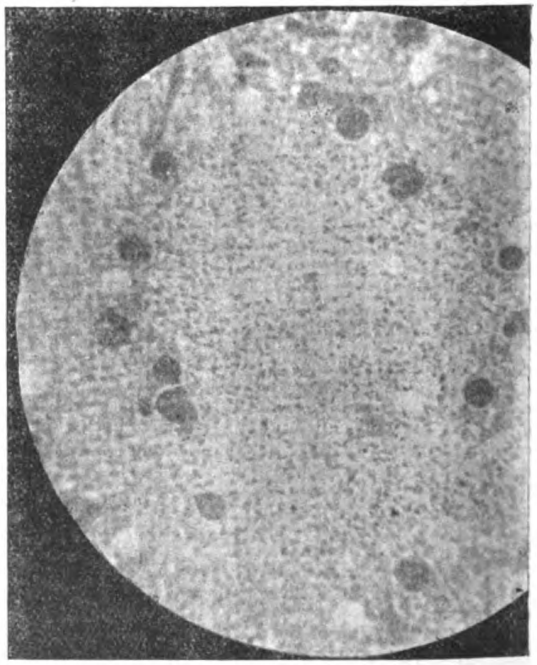
*Course of disease.*—The patient's condition has been precarious. Delirium has been almost continuous, although slight, and at no time violent. The pulse has been very feeble and its rate under 100. Hiccough was present from August 30th till Sept. 8th, though not in a distressing degree. It is of interest to note in this case that without any evidence of pulmonary lesion the respiration rate has varied between 24 and 30. Until the morning of Sept. 2nd the temperature ran a febrile course, varying between 100·6° and 103°. On that morning the patient had a distinct crisis and the temperature fell to 97·6° and there was improved tension in the patient's pulse and he expressed himself as feeling better. After admission the redness and œdema surrounding the swelling in the groin slowly spread until it extended downwards almost to the mid-thigh and backwards over the buttock. At the same time œdema without redness spread from the right iliac region until nearly the whole abdominal wall pitted readily on pressure. This was associated with a distinct increase in the abdominal distension. The inflammatory process reached its height on Sept. 1st and after that date there was a slow but distinct subsidence of the redness and œdema around the bubo. The œdema of the abdominal wall disappeared, but there appeared coincident with this considerable œdema of the left foot, with tendency to the formation of pressure sores. On Sept. 6th a secondary fever due to suppuration of the bubo commenced, and the temperature

FIG. 1.



Shows the patient on admission.

FIG. 2.



A pure cultur of bacillus pestis.

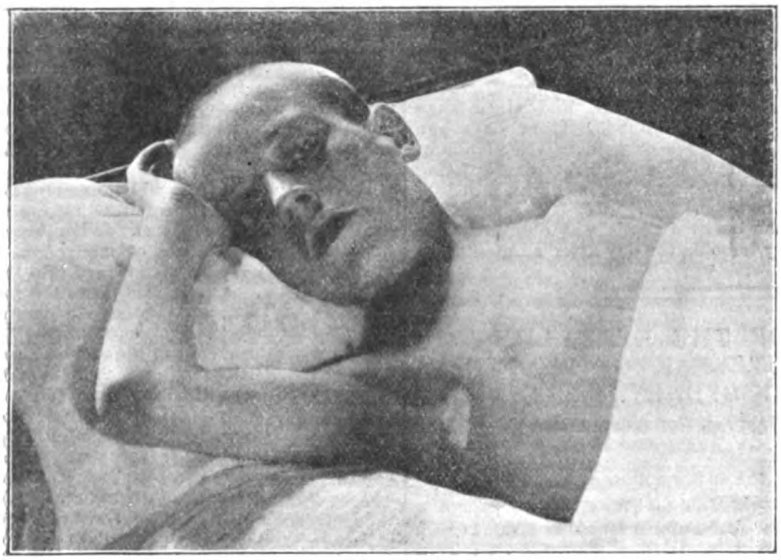
rose gradually until it has now (Sept. 12th) reached 101°. The patient was at the date of writing extremely feeble.

A pure culture of bacillus pestis (Fig. 2) was obtained from puncture of the bubo on the night of admission.

(5) Thomas Horn, aged 14 years, 6, South Coburg-street, was admitted to hospital on August 29th, his case being certified as "enteric fever (?)." The patient was at the house of Mrs. Malloy on either August 20th or 21st. He sickened on the 23rd. The incubation period in this case is therefore two or three days. On the 23rd the patient was seized with headache, retching, and pain in the back and right axilla. He was fevered, restless, and delirious at nights after the onset of illness. The pain in the right axilla rapidly became worse and was followed by pain in the left side of the neck and in the right groin.

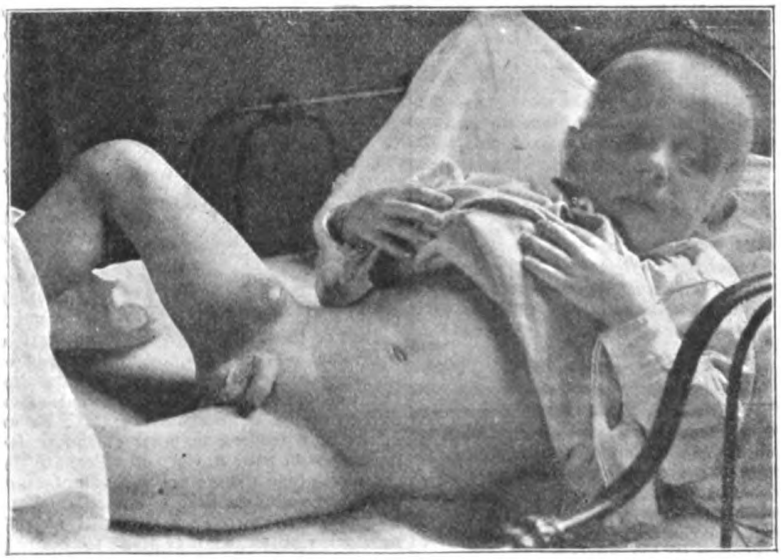
*On admission* the patient's face was flushed and the expression was dull and heavy. He had the same apprehensive expression described in previous reports. The pupils were dilated and the conjunctivæ were fairly clear. The lips were dry and there was well-defined circum-oral pallor. The tongue was coated in the centre with a greyish white fur, but was clean and moist at the tip and edges. The skin was hot and dry; it presented a faint mottling which was most marked on the back, flanks, and buttocks. As the patient lay in the dorsal decubitus the right thigh was slightly abducted and the leg was semi-flexed. There was a general enlargement of the glands in the groins, the axillæ, and the neck. The glands in the right axilla and the right groin were distinctly the largest and exceedingly tender (Fig. 3). No complaint of pain was made on palpation of the glands of the left groin, the left axilla, or the neck. The skin over the right axilla and the right groin was slightly reddened, but was not œdematous. The temperature was 104·6° F., the pulse was 140, and the respirations were 26. The pulse was easily compressible, but quite regular. The respirations were easy. Examination of the lungs revealed nothing except a few sub-crepitant râles in the left baso-lateral region. On auscultation over the cardiac area a faint systolic murmur was heard both at the apex and in the pulmonic region. The abdomen was slightly tympanitic

FIG. 3.



Shows the patient on admission.

FIG. 4.



Shows another patient on admission whose clinical history is not recorded in this article

to percussion, especially in the right iliac region. The spleen was enlarged both in its longitudinal and transverse diameters.

*Course of disease.*—Until Sept. 2nd the general condition remained the same. There was no visible increase in the size of the enlarged glands. He was very restless at nights, having delirium with delusions. Fever was high, the temperature ranging from 103° to 105°. The pulse was rapid and feeble. Considering the stress and duration of the fever there was a notable absence of some of the commoner symptoms of high fever—viz., subsultus tendinum and dryness of the mouth and tongue. Headache was constantly present. On August 31st a marked injection of the right eye was observed with slight prominence of the eyeball. On Sept. 2nd a consignment of Yersin's anti-plague serum was received. It was decided after consultation that this patient was a suitable subject for serum treatment. Accordingly at 12 midnight an intravenous injection of 15 cubic centimetres and at the same time a subcutaneous injection of 25 cubic centimetres of the serum were made. The patient slept well after the injections and perspired freely for the first time since admission. Next day brought no remission of the temperature, but the buboes in the right groin, which had been extremely tender on the previous day, could now be touched without the patient experiencing more than a slight sense of pain. A like lessening in the tenderness of the axillary bubo was also quite manifest. A fall of temperature amounting to 4° occurred on the night of Sept. 3rd, and since then the improvement has been maintained. Three days ago (Sept. 9th) there was occurrence of pain in the glands of the right groin associated with a temperature oscillating between normal in the morning and 101° at night, probably due to suppuration of the bubo.

A pure culture of the bacillus pestis was obtained after puncture of the axillary bubo on the day after admission.

## A SUMMARY OF THE EVENTS IN THE RECENT OUTBREAK OF PLAGUE IN SYDNEY.

(FROM A SPECIAL CORRESPONDENT.)

THE population of the metropolitan combined sanitary districts of Sydney is 456,000, all being whites except a small colony of Chinese who number less than 4000. Cases and deaths occurred as shown in the table below; included among them are 10 Chinese, all males, of whom eight died. The first case appeared during the week ending Jan. 27th, and up to July 28th there had been 302 cases and 102 deaths.

| Week ending | Number of cases. | Result. | Week ending | Number of cases. | Result. |
|---|---|---|---|---|---|

Before the plague came the provisions of the Venice Convention were applied to vessels arriving from plague-infected ports, efforts were made to kill the rats on them, and notification of all cases of plague was made compulsory under the Public Health Act as soon as the presence of the disease in New Caledonia became known. On the appearance of the first case the Registrar-General was requested to communicate to the department every information of death received by him after Jan. 1st, 1900, in which the cause was ascribed to blood-poisoning, septicæmia, acute abscess, septic intoxication, &c., with a view to investigation by the medical staff. It was publicly requested that all cases of illness of doubtful character should be reported to the department. This request was also specially addressed to the members of the medical profession by letter. Suspicious or doubtful cases thus reported were examined and diagnosed by a staff medical officer. On the appearance of the second case the coroners were desired to report all uncertified cases of death in which there was suspicion of plague, in order that the examination of the bodies might be supervised and to secure safe burial if plague were found to have been the cause of death.

Facilities for examining cases bacteriologically already existed in the excellent laboratories possessed by the department and under direction of a highly-trained microbiologist. A supply of plague prophylactic (Haffkine) had been procured long before and was in readiness. At first it was used for inoculating the staff and contacts only. A further supply was received during the second week of the outbreak and was used on contacts and on persons inhabiting parts of the city which appeared to be specially dangerous; this supply was continuously maintained by receipt of fresh consignments from India. Posters were exhibited in the streets in which brief information concerning plague and instructions to householders were given, and pamphlets to a similar effect were sent by post to every householder; the posters were also printed in Chinese, and exhibited in the small Chinese quarters which exist in Sydney.

Parts of the city from which numerous cases of plague had been removed were regarded as infected areas. They were dealt with under the quarantine law, surrounded by a guard, and then large numbers of men controlled by the Department of Public Works were turned into them who thoroughly cleansed them. A staff was organised for the destruction of rats. In addition, a capitation fee of sixpence for every rat was paid through the agency of the staff last mentioned and also through the agency of the various municipal councils controlling the districts into which Sydney is subdivided. The sewers were from time to time fumigated with burning sulphur by the staff of the engineer for water-supply and sewerage. This had the effect of killing some rats and of driving large numbers to the sewer mouth where they were drowned or destroyed. Another staff was organised which had for its duty to fumigate regularly with burning sulphur the ferry boats which ply on the harbour so as to destroy the rats. This duty was entrusted to the collector of customs. It was ordered that no vessel trading between Sydney, which was the only infected place, and other ports of New South Wales should be allowed to communicate with the shore unless it could produce a certificate that before leaving Sydney it had been fumigated and the rats had been destroyed. This duty was entrusted to a branch of the last-named staff. Vessels of all descriptions were forbidden to lie at any public wharf except under regulations calculated to prevent the landing of rats from them. They were to be kept four feet off the wharf by fenders—the fenders and gangways in use to be kept freshly tarred, springs and hawsers to be tarred, all openings in the vessel on the wharf side to be closed except when in actual use, all openings to be closed at night and the side to be brightly lighted, &c.

All local authorities were reminded of their powers and duties under the Public Health Act and the Municipalities Act and were exhorted to use great exertions to get rid of all accumulations of filth and of nuisances in general. Local authorities in country districts in communication with Sydney by sea or by rail were requested to secure the refusal of some cottage suitably placed in which a plague patient might be lodged if imported from Sydney.

Part of the maritime quarantine station was equipped and utilised as a plague hospital. A staff of experienced trained nurses was drawn from a general hospital under control of the department. A staff medical officer was placed in charge of the quarantine hospital; he was assisted by the advice of a leading member of the profession practising in Sydney who paid a visit on alternate days. Clergymen of three religious denominations volunteered for service at the quarantine station and officiated during its occupancy for plague purposes. They, as well as medical officers and medical visitors who desired to study the disease, were allowed to enter and leave the hospital enclosure on first

changing their clothes and on bathing before leaving if they had been inoculated.

Buildings at the maritime quarantine station standing outside the hospital enclosure, which are generally employed for housing healthy persons landed from infected vessels, were used as an isolation camp for contacts.

Communication with the quarantine station being by sea a service of steam-vessels was organised, by means of which communication could be had immediately at any time that a case was reported for removal. These vessels lay at a central depôt within the city, which was placed in quarantine. A special ambulance service was equipped for the purpose of removing cases of plague; it was lodged at the central depôt above-mentioned. A disinfecting staff was organised and lodged at the same central depôt. This was placed under control of the medical officer of health of the metropolitan combined sanitary districts.

All cases of plague or suspected plague were notified to the department direct; they were then visited by a staff medical officer. As soon as the staff medical officer had made up his mind that the case was plague he administered subcutaneously 40 cubic centimetres of Yersin-Roux serum (as soon as this became available on May 12th), communicated with the nearest police-station, forthwith placed the house and all persons in it in strict quarantine under a police guard, and reported.

When a staff medical officer's report was received (by telephone or otherwise) at the department, the ambulance staff was instructed to fetch the patient and, in separate vehicles, the other members of the household. A trained nurse accompanied the patient and attended to his needs during the journey.

On arrival at the maritime quarantine station protective inoculation was offered to the contacts; it was rarely accepted. On arrival contacts were deprived of their own clothes and were given clean clothes; their own clothes were restored to them after washing or disinfection in a steam disinfector. Contacts, whether inoculated or not, were detained for five complete days and were then dismissed. Patients were discharged from hospital (*a*) if they had had a normal temperature for 10 days, (*b*) if they had no discharging sore, and (*c*) if they were, generally speaking, strong enough.

The bodies of persons (*a*) who were too ill on discovery for removal, (*b*) who were found already dead, or (*c*) who after investigation on report of coroners were found to have died from plague were dealt with as follows. The body was completely enveloped in a sheet soaked in sublimate solution and placed in a light coffin having watertight joints at the bottom. The coffin was screwed down; it was enveloped in coarse sheeting soaked in sublimate solution; it was then safely transported by the undertaker to the depôt already mentioned and thence to the maritime quarantine station, where it was buried without further precaution in a sandy soil on a slope falling towards cliffs above the Pacific. The bodies of persons who died at the quarantine hospital were coffined after a similar fashion in the hospital enclosure by the male nurses, who also carried them to the gate. They were then taken in charge by appointed persons who transferred them to the place of burial mentioned above.

After the house from which the patient had been removed was evacuated it was locked and remained in charge of the police who prevented general access to it. As soon as possible the disinfecting staff took possession of it. Usual methods of disinfection were used: sublimate solution was applied with Geneste-Hirscher sprays inside, solutions of 5 per cent. sulphuric acid being used for yards and basements. Clothing, bedding, and soft goods generally were removed in canvas bags to the steam disinfector. The routine of disinfection varied slightly according to circumstances in individual cases; the whole premises were always thoroughly cleansed, but often only the room occupied by the patient was actually disinfected. Articles removed for disinfection having been replaced, the contacts resumed occupation at the beginning of the sixth day from their removal.

August 8th.

---

ALUM IN BAKING POWDER.—At the Bristol police-court on Sept. 5th a grocer was summoned for selling baking powder containing 52 per cent. of alum. He was fined 40*s.* and costs and informed that a second offence would result in imprisonment.

## POST-GRADUATE INSTRUCTION.

AT the beginning of the new medical session, which is now within a measurable distance of us, many qualified men will like to know the opportunities which are offered them in London for keeping up to date in their clinical work. The union of nine of the Metropolitan Schools of Medicine offers the best of these opportunities. A ticket for three months or six months can be obtained which entitles its holder to attend the clinical instruction, the operations, and the post-mortem examinations at each of the following hospitals, viz., Charing-cross, Guy's, King's College, Middlesex, St. George's, St. Mary's, St. Thomas's, University College, and Westminster. It will be seen at once what a wealth of material is open to those who desire to see as many cases as possible in a short period, and practitioners will be difficult to please if they do not find enough cases of real interest to study. If the scheme were more widely known there would be fewer who consider that they must go to Paris, Berlin, or Vienna to obtain clinical instruction. Particulars may be obtained on application to the honorary secretary, Metropolitan Schools of Medicine, west wing, Examination Hall, Victoria-embankment, London, W.C., between the hours of 12.30 and 3 P.M. daily, except on Saturdays.

*Medical Graduates' College and Polyclinic, 22, Chenies-street, Gower-street, W.C.*—This institution was established in 1898. Its principal object is to organise and to develop post-graduation study in the metropolis. The enormous field for clinical study which exists in London has failed to attract medical graduates in any considerable number largely because the existing facilities are but imperfectly known and the clinical teaching is not definitely organised to meet the wants of practitioners. The establishment of a central office where precise information may be obtained will, it is hoped by those interested in the institution, be of some influence in placing London in the position it ought to occupy as the most important centre for post-graduation study. In addition to an endeavour to secure coöperation among existing institutions the new College provides practical instruction under its own roof in all the special departments of professional work. It is well equipped with consulting-rooms, class-rooms, laboratory, lantern-room, dark-room, &c. There is also a well-furnished reading-room and library. In the Polyclinic consultations are conducted every afternoon at 4 o'clock by well-known physicians and surgeons. Patients whose circumstances warrant it may be sent by any medical practitioner and the opinion of the consultant is communicated not to the patient but to his medical adviser. Records of the cases are made and the valuable clinical material thus collected is to be published in the College journal. The annual subscription is fixed at present at one guinea. This secures the use of the library, reading-room, and museum with the right to attend the afternoon consultations. There are also at intervals special clinical lectures which are open to all annual subscribers. Medical visitors to London are invited to inspect the College, and further information may be obtained by application to the medical superintendent. The President of the College is Sir William H. Broadbent, Bart.

*Charing Cross Hospital.*—Special series of clinical lectures and practical demonstrations, exclusively arranged for the convenience of practitioners and post-graduate students, are given at the hospital throughout the year. The lectures for the year are arranged in three courses, each course consisting of 10 meetings and lasting 10 weeks. Two of these courses are held during the winter and one during the summer. The class meets on each Thursday in the board-room of the hospital and proceeds thence to the wards or to the department in which the demonstration may be held. The fee at present charged for each course of 10 lectures is one guinea. The first of the two winter courses for the ensuing academical year will commence on Oct. 11th next and will be conducted by the following members of the medical and surgical staff: Dr. T. H. Green, Dr. J. M. Bruce, Dr. F. Willcocks, Dr. H. M. Murray, Dr. J. Galloway, Dr. T. W. Eden, and Mr. S. Boyd, Mr. H. F. Waterhouse, Mr. F. C. Wallis, and Mr. C. Gibbs. Practitioners wishing to join the class can obtain any further information as to the

dates and the subjects by communicating with the honorary secretary (Dr. F. Willcocks) at the hospital.

*West London Hospital.*—This hospital was the first, and still is the only, general hospital in London to organise a systematic scheme for post-graduate teaching and to devote the clinical material in its wards and in its out-patient department to the instruction of qualified men. This scheme was started in 1895 and three years later its basis was enlarged by the provision of accommodation in the shape of lecture-, reading-, and writing-rooms for the post-graduates. For the proper organisation of post-graduate teaching a general hospital is essential, and it is absolutely necessary that the practice of such hospital should be exclusively reserved for qualified medical men. The proof of this statement is to be found in the success which has attended this college. The large number of post-graduates who have been enrolled since its commencement (over 300) at first strained the accommodation resources of the hospital, especially in the out-patient department, but a much-needed enlargement of this department carried out by the committee last year now affords ample space for a large class of post-graduates. The scheme of study includes the following: 1. Instruction is given daily in the medical and surgical out-patient rooms. 2. Special demonstrations are given in the medical and surgical wards on fixed days in each week. 3. Practical instruction is given in the special departments for diseases of the eye, throat, nose and ear, and of women, and clinical assistants are appointed in connexion therewith. 4. Instruction is given in the post-mortem room and in the clinical investigation laboratory. 5. Every facility is afforded to the post-graduates for seeing and following the operations performed in the operating theatre, over 1000 operations being performed each year, and they are encouraged to render assistance thereat. 6. Courses of practical lectures are held three or four times in the year, two lectures being given in each week. A certificate, signed by the staff, is awarded after three months' attendance. The fees for hospital practice, including all lectures, are £3 3*s.* for three months, or £5 5*s.* for one year. Full information can be obtained on application to the Dean, Mr. L. A. Bidwell, at the hospital.

*West-End Hospital for Diseases of the Nervous System.*—Clinical demonstrations on cases of diseases of the nervous system are held each Tuesday afternoon at 4 o'clock throughout the winter for medical practitioners. Medical men are admitted on presentation of their visiting cards, but the fee for a course of three months is one guinea. The courses are also sometimes held during the spring and autumn vacations for medical men visiting the metropolis. The programme of subjects held during the winter courses is so arranged as to cover the main subjects included in neurology. The subjects are always practical and cases are always shown. A synopsis of each demonstration is sent by post beforehand to those who join for the course. As this course caters solely for practitioners it does not clash with that given at the National Hospital for the Paralysed and Epileptic which is for students also. Further information may be obtained from the honorary secretary, Post-Graduation Course, at the hospital, 73, Welbeck-street, W.

*** For Post-graduate instruction abroad see the Students' Number of THE LANCET for Sept. 2nd, 1899, page 692.

## THE REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR 1898.

FIRST NOTICE.

THIS report, with its appendices and returns, forms a weighty official document in a double sense—that is, not only in the matter of avoirdupois, but in the amount and value of the information which it contains. We do not think that these reports are so well known as they should be, for they contain a variety of information not easily to be obtained elsewhere. A perusal of the list of books and papers referred to by the compilers of this volume will show the labour involved in drawing up these reports. We may enumerate some of the subjects discussed, and as our observations must be very brief we strongly recommend our readers to study the report for themselves.

In addition to the sections devoted to the diseases affecting the European and native armies of India, the jail and general population, we have one upon enteric fever in which the subject is very elaborately and carefully treated in connexion with all the more recent views put forward in contemporary medical literature—in Europe and America. There is also a contribution on the detection of the bacillus typhi abdominalis in water and other substances by Mr. H. Hankin, Fellow of St. John's College, Cambridge, the chemical examiner and bacteriologist to the North-West Provinces and Oudh and to the Central Provinces. A very interesting reference is made to some points in connexion with plague and a brief summary of the report of the German Plague Commission is given; while among other contents of the report we may mention some valuable observations on the sewage problem and the different methods adopted for the disposal of excreta in India; a *résumé* of Professor's Sticker's paper on Leprosy as the result of his observations and experience whilst serving in India as a member of the German Plague Commission; and a capital, as well as very readable, report by Dr. Alexander Crombie of the recent Congress on Tuberculosis at Berlin (at which he was present as a delegate from the Indian Government), supplemented by observations having special reference to the prevalence and prevention of that disease in India.

The health of the European army in India, the average strength of which in 1898 was 67,741, was better as measured by the admissions, constantly sick, and death rates, but the total loss from deaths and invaliding together was higher than in the previous year. Ague and venereal disease, although less in 1898 than in the previous year, made up more than half the total admission-rate from all causes. But the diseases which caused this admission rate were not by any means those which gave rise to the mortality in the British army serving in India. Enteric fever caused more than half the total death-rate. The mortality from this fever, abscess of the liver, and heatstroke combined made up 65 per cent. of the total deaths for the year. As far as northern India is concerned the health statistics were no doubt unfavourably affected by the return of soldiers more or less broken down in health from frontier field service. We notice that the highest death-rate occurred in the 2nd battalion of the Yorkshire regiment at Peshawar and that no less than 52·9 of it was attributable to enteric fever. A large part of the Sanitary Commissioner's report is devoted to the consideration of this fever and the subject is very thoroughly discussed—indeed, we do not know any other published reports in which the views of Continental, British, and American authorities in regard to its origin, causes, modes of spread, and etiology are so amply set forth. We wish we could add that the result of all the labour bestowed upon the subject was more encouraging than it is. Enteric fever is the most fatal of all the diseases to which the European army in India is subject and, judging by statistics, it seems to be increasingly so. Not so very long ago it was comprehensively regarded and relegated to one cause, that of a water-borne disease; but this exclusive view is no longer held to be tenable. Its causation is now attributed to the presence of the enteric fever bacillus of Eberth and Gaffky and, as a consequence, the fever is intimately associated with the life-history of this pathogenetic germ and the methods by which it effects an entrance into the human body. It is confessedly somewhat bewildering to those who are seeking how to formulate some practical line of action in regard to the prevention of enteric fever to read all the various theories and hypotheses that have been, and are still being, put forward. A much more comprehensive view is now taken as to what is and what is not enteric fever. Not only are cases nowadays included under that term which the late Sir William Jenner, for example, would probably not have recognised as belonging to it, such as those of enteric fever without intestinal lesions, but the latest researches open out fresh paths for investigation. The great body of opinion, and the results of bacteriological researches, are in favour of the view that the enteric fever of India is the same as that of Europe, although cases may occur in both countries caused by other and related bacilli. Assuming that the bacillus is the veritable cause of enteric fever, the facts that it can be so frequently detected in the urine and that its presence is often discoverable in the gall-bladder and various organs and tissues long after a patient has recovered from an attack of enteric fever, tend to show how much more complex and difficult is the problem

of preventing the spread of the disease than it was when the intestinal discharges were believed to be the sole or main vehicle for dissemination of the virus. The enteric fever age belongs to that period of life of which short service armies are composed, and the predisposition to be attacked by it in tropical and sub-tropical climates is in inverse proportion to the length of service in such climates—in other words, the shorter the residence the greater the liability to attack. This may be now regarded as a fact established by Indian statistics. A good deal has been said of late about the prevalence of enteric fever among the native population in India. If such were the case we should not, of course, have far to go to seek for a widespread cause of its prevalence among British troops serving in that country; but the facts, so far as these are known, all point the other way—namely, that the natives enjoy a comparative immunity from enteric fever. It is commonly alleged that the natives suffer from that disease in childhood—hence their subsequent immunity; but no evidence has been brought forward in support of that view, and it is notorious that the amount of enteric fever among the native army and jail population is quite insignificant as compared with what it is among Europeans quartered in India. Put shortly, the disease from which the native soldier dies is pneumonia and respiratory disease during the cold season; that from which the British soldier dies is enteric fever contracted in the hot season. It is noteworthy, too, that the class of native troops most liable to be affected by enteric fever are those whose diet and habits most nearly resemble our own—the Goorkhas, for example. If we might hazard a conjecture it would be that those who are not meat-eaters and spirit-drinkers in these climates are less liable to attack, and that their fæcal discharges are of quite a non-infective character as compared with those who consume meat and alcohol. Be this as it may, however, the loss of young manhood in India and the drain on this country from this disease are appalling, and no amount of trouble and expense can be considered excessive when employed in searching out and preventing its causes.

The history of plague in India during 1898 shows that, as far as the British troops were concerned, the chances of their contracting the disease by infection were very small, notwithstanding the fact that numbers of them were employed on plague duty. In case of cholera the movement of British troops in seven instances during 1898 was resorted to with success; and similarly in the case of plague the evacuation of an infected site or of the lines occupied by the native followers of a corps was found to be the most effectual plan of procedure. The best methods by which we can combat plague comprise: evacuation of the site, measures of disinfection, and anti-plague inoculation on the same principle as we vaccinate against small-pox; and the most practical guide that we have seen is a little pamphlet on bubonic plague by Mr. Hankin, published at the Pioneer Press, Allahabad, in 1899. As regards the way to proceed in the case of a village or small community a recent report by the Punjab Government may be consulted. In this report the rôle played by rats and the reasons for an immediate and wholesale evacuation of a plague-infected locality are set forth in an interesting and instructive way. The report states that the advantages of evacuation and thorough disinfection of a whole village site have been so accepted as fully proved that little argument has been used regarding them. A comparison of the ultimate results in a number of cases where immediate evacuation was not insisted on with those of later villages where no delay was allowed to occur will show clearly the necessity of having all villages camped out in the open air at the earliest possible moment. The argument is this. Plague shows no tendency to spread from house to house unless it is carried by human beings or animals. Rats take the disease, and it is admitted that after being infected they have no tendency to leave their homes unless they are disturbed, and that in 10 days all that live in the infected houses should have died. If, however, they are disturbed by the roofs being at once taken off infected houses, floors being dug up, and everything being flooded with antiseptics, they leave the infected houses and carry the infection to other houses. In front, therefore, of the line of disinfection through a village there is an advancing wave of infection carried by the rats, and when the disinfection reaches the last house in the village the remaining rats must either double back into the houses already disinfected, thus re-infecting them, or they must leave the village and carry the infection to some other village, and either result is clearly one to be avoided. Given the premisses the conclusion and the rule would therefore be sound.

## THE OUTBREAK OF TYPHOID FEVER IN BELFAST.

AT the present time the citizens of Belfast are being treated to an interesting discussion as to the cause of the typhoid fever in the city. In the middle of July the executive sanitary officer and the city surveyor of Belfast reported to a joint meeting of the improvement and public health committees of the corporation as to how the health of the city could be improved with special reference to typhoid fever, and they made a number of suggestions, as reported in THE LANCET of July 21st (p. 224). The executive sanitary officer reported that there would be no protection against epidemics of typhoid fever until the Water Commissioners carried out the powers which they obtained from Parliament last year, when in referring to their catchment the chief engineer of that trust stated that "a condition of things like that on the catchment is a standing menace to the health and life of the people in the town where the water is consumed." In reply to this report the chief engineer of the Water Commissioners supplied his board with a counter report which was presented at their meeting on August 30th. He said that the conclusion that the recent cases of typhoid fever in Belfast found their origin in the Stoneyford catchment was unsupported by any real evidence. As against such a view he brought forward the long storage and subsidence of the water; very careful filtration; further storage in the service reservoir; turning the water to waste when any doubt existed as to its suitability for use; and the fact that the disease did not show itself fairly distributed over the whole district receiving a supply from Stoneyford, but in a particular portion. He then twitted the corporation officials with the fact that while they admitted serious defects in the sanitary condition of Belfast and made a number of general recommendations in connexion with them, they utterly failed to draw any conclusion as to the relationship between the sanitary conditions and the prevalent disease. He traced the origin of the epidemic to bad drains, stinking privies and ashpits, sewer gas, and unhealthy sites in Belfast. He pointed out that there were thousands of spots in Belfast soaking with organic pollution, teeming with germ life, and ready when conditions were favourable to seek out new victims. He pointed out how disease-germs, which die in water in a few weeks, live and multiply at an enormous rate in soil when it is charged with organic filth. He showed (by quoting statistics, giving some returns of drain-testers employed by the public health committee) the deplorable condition of drain-jointing in Belfast. One tester found, out of 819 houses in which typhoid fever had occurred, some 388, or 44 per cent., with defective drains. In a further batch of 137 houses the drains in over 78 per cent. were wrong; and another tester stated that out of 731 houses in which typhoid fever had occurred 389 houses, or 53 per cent., had defective drains. On the question of things sanitary in Belfast the engineer of the Water Board referred to a paragraph quoted in Question 4040, noted in the Belfast Bill of 1896, as follows:—"No language could be too strong to express public disapproval of the practice of wilfully constructing improper sewers or drains and anyone even moderately acquainted with the character of the Belfast buildings must be alive to the fact that this almost criminal negligence is more widespread than they would care to acknowledge." The engineer of the Water Board attacked the whole system of the Belfast main drainage, pointing out that the sewers were too small for their work and that the assumption that the main drainage system had freed the brooks and streams from sewage was incorrect. He showed that the Water Commissioners were, and had been, pushing on as fast as possible their plans to acquire the catchment areas. Taking the table of death-rates from typhoid fever in Belfast for the period 1890–1899, excluding the two epidemic years, he showed that the average or normal death-rate from typhoid fever was 54 per 1000 persons per annum, while in the 33 great towns in England for the period 1888–1897 the rate was 19 per 1000.

In other words, independently of epidemics, the annual average or normal death-rate from typhoid fever in Belfast was almost three times the rate in the 33 great towns.[1] He pointed out how the corporate officials had been absolutely silent on this point—viz., that typhoid fever was really endemic in Belfast, the inference being that sanitary defects, not bad water, must be the cause of this, precisely an analogous condition to Dublin where, though the water-supply was admittedly good, typhoid fever was endemic. The engineer of the Water Board claimed to have shown that the visitation of typhoid fever could not be fairly attributed to the Stoneyford water-supply, and he held that other causes and insanitary conditions (which he pointed out) were sufficient to account for all the disease that had occurred, causes and conditions to which he accused the officials of the corporation of having shut their eyes in their report. He quoted Dr. Frankland (in support of the Belfast Water Bill of 1899), who, while supporting the proposals to buy up the water-works catchments, states: "I do not think any case has been made out against the water as having produced the epidemics (of typhoid fever) which Belfast has been subject to from time to time." Finally, the engineer of the Water Commissioners expressed his surprise that, in the present sanitary deadlock now existing in Belfast the public health committee of the corporation did not have an exhaustive examination of the city made by an eminent public expert in public health, such as Dr. A. Hill of Birmingham or Sir Henry Littlejohn of Edinburgh. The public have now heard both sides of the case, that of the public health committee who say the water-supply was the cause of the epidemic, and that of the Water Commissioners who deny this altogether, but blame the bad sanitary state of the city as being the *fons et origo mali*. Meantime, while this wrangling goes on between the City Corporation of Belfast and the Water Board. 62 cases of typhoid fever were notified for the week ending August 26th. No attempt has so far been made to meet the damaging attack of the official of the Water Commissioners. At the monthly meeting of the city council held on Sept. 1st it came out that during the period between July 22nd and August 18th 209 cases of typhoid fever had been notified, 78 of simple continued fever, 36 of scarlet fever, 26 of erysipelas, eight of diphtheria, four of puerperal fever, two of croup, and one of small-pox. The number of cases of typhoid fever, as well as the deaths therefrom are slightly more numerous than in the preceding four weeks. It was extremely unfortunate that just when the council were beginning to discuss this most important question of the typhoid fever outbreak the meeting became so small that the necessary quorum was not present and the consideration of the matter had to be adjourned.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 7042 births and 4824 deaths were registered during the week ending Sept. 1st. The annual rate of mortality in these towns, which had been 20·3, 19·5, and 19·8 per 1000 in the three preceding weeks, rose again during the week under notice to 21·7. In London the rate was 20·2 per 1000, while it averaged 22·6 in the 32 provincial towns. The lowest death-rates in these towns were 11·9 in Halifax, 12·3 in Croydon, 14·1 in Bradford, and 14·2 in Cardiff; the highest rates were 27·9 in Birmingham, 30·6 in Hull, 33·3 in Preston, and 33·6 in Sheffield. The 4824 deaths in these towns included 1422 which were referred to the principal zymotic diseases, against 1061 and 1180 in the two preceding weeks; of these 1156 resulted from diarrhœa, 97 from whooping-cough, 49 from diphtheria, 48 from "fever" (principally enteric), 45 from measles, 24 from scarlet fever and three from small-pox. The lowest death-rates from these diseases were recorded in Halifax, Bradford, Newcastle-upon-Tyne, and Birkenhead; and the highest rates in Bolton, Sheffield, Preston, and Hull. The greatest mortality from measles occurred in West Ham and Swansea; from scarlet fever in Burnley; from whooping-cough in Cardiff, Brighton, and Gateshead; from "fever" in Portsmouth; and from diarrhœa in Birmingham, Bolton, Preston, and Hull. The 49 deaths from diphtheria included 19 in London, 10 in Sheffield, six in Leicester, and three in Leeds. Three cases of small-pox were registered in Liverpool, but not one in any other of the 33 towns. There were two cases of small-pox under treatment in the Metropolitan Asylums Hospitals on Saturday, Sept. 1st, one fresh case having been admitted during the week. The number of scarlet fever patients in the Metropolitan Asylums Hospitals and the London Fever Hospital at the end of the week was 1702, against numbers decreasing from 1838 to 1726 on the three preceding Saturdays; 176 new cases were admitted during the week, against 155, 157, and 140 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had increased from 128 to 149 in the three preceding weeks, fell again during the week under notice to 138, and were three below the corrected average. The causes of 51, or nearly 1·1 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Leicester, Nottingham, Bradford, and in 11 other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Halifax, Sheffield, and Hull.

In 33 of the largest English towns 6888 births and 4375 deaths were registered during the week ending Sept. 8th. The annual rate of mortality in these towns, which had increased from 19·5 to 21·7 per 1000 in the three preceding weeks, declined again to 19·6 last week. In London the death-rate was 18·0 per 1000, while it averaged 20·7 in the 32 large provincial towns. The lowest death-rates in these towns were 10·1 in Derby, 12·4 in Halifax, 12·7 in Bradford, and 13·3 in Blackburn; the highest rates were 25·9 in Sheffield, 26·4 in Leicester, 26·8 in Preston, and 35·6 in Hull. The 4375 deaths in these towns included 1144 which were referred to the principal zymotic diseases, against 1060, 1181, and 1422 in the three preceding weeks; of these 871 resulted from diarrhœa, 101 from whooping-cough, 63 from diphtheria, 52 from "fever" (principally enteric), 37 from measles, and 20 from scarlet fever. The lowest death-rates last week from these diseases occurred in Halifax, Bradford, Blackburn, and Huddersfield; and the highest rates in Wolverhampton, Leicester, Burnley, and Hull. The greatest mortality from measles and from scarlet fever occurred in Oldham; from whooping-cough in West Ham, Nottingham, Derby, Preston, Sheffield, and Gateshead; from "fever" in Portsmouth; and from diarrhœa in Brighton, Wolverhampton, Leicester, Bolton, Manchester, Burnley, and Hull. The 63 deaths from diphtheria included 19 in London, 13 in Leicester, eight in Sheffield, four in Bristol, and four in Manchester. No fatal case of small-pox was registered last week in any of the 33 towns and only three small-pox patients were under treatment on Saturday last, Sept. 8th, in the Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1736, against numbers declining from 1838 to 1702 on the four preceding Saturdays; 213 new cases were admitted during the week, against 157, 140, and 176 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 149 and 138 in the two preceding weeks, further declined last week to 124, and were 25 below the corrected average. The causes of 44, or 1·0 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Manchester, Salford, Newcastle, and in 13 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Norwich, Liverpool, and Halifax.

### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined from 19·0 to 16·9 per 1000 in the five preceding weeks, rose again to 17·6 during the week ending Sept. 1st, and was 4·1 per 1000 less than the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 13·2 in Leith and 13·7 in Dundee to 22·6 in Paisley and 24·4 in Aberdeen. The deaths in these towns included 54 which were referred to diarrhœa, 25 to whooping-cough, nine to measles, five to scarlet fever, five to "fever," and three to diphtheria. In all 101 deaths resulted from these principal zymotic diseases, against 108 and 103 in the two preceding

[1] Local Government Board Report, 1898-99, p. 167.

weeks. These 101 deaths were equal to an annual rate of 3·3 per 1000, which was 1·5 below the mean rate in the week from the same diseases in the 33 large English towns. The fatal cases of diarrhœa, which had been 56 and 52 in the two preceding weeks, rose again to 54, of which 27 occurred in Glasgow, six in Dundee, and six in Greenock. The deaths referred to whooping-cough, which had been 18 and 23 in the two preceding weeks, rose again to 25, 16 of which were recorded in Glasgow. The deaths from measles, which had been 16 and nine in the two previous weeks, were again nine during the week under notice, and included five registered in Edinburgh. The five deaths from scarlet fever corresponded with the number in the preceding week, and included three in Glasgow and two in Edinburgh. The fatal cases of "fever," which had been five and eight in the two preceding weeks, fell again to five, three of which were recorded in Glasgow, where two of the three deaths from diphtheria also occurred. The deaths from diseases of the respiratory organs in these towns, which had been 59 and 82 in the two preceding weeks, declined to 58 during the week under notice, and were 25 below the number in the corresponding week of last year. The causes of 19, or 3·5 per cent., of the deaths in these eight towns were not certified.

The annual rate of mortality in the eight Scotch towns, which had been 17·9 and 17·6 per 1000 in the two preceding weeks, further declined to 17·5 during the week ending Sept. 8th, and was 2·1 per 1000 less than the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 14·6 in Paisley and 15·1 in Edinburgh to 21·9 in Aberdeen and 23·2 in Greenock. The 540 deaths in these towns included 42 which were referred to diarrhœa, 21 to whooping-cough, seven to measles, five to diphtheria, four to scarlet fever, and four to "fever" (including one death from bubonic plague). In all 83 deaths resulted from these zymotic diseases, against 108, 103, and 101 in the three preceding weeks. These 83 deaths were equal to an annual rate of 2·7 per 1000, which was 2·4 below the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of diarrhœa, which had been 52 and 54 in the two preceding weeks, further declined last week to 42, of which 17 occurred in Glasgow, nine in Edinburgh, six in Dundee, and six in Aberdeen. The deaths from whooping-cough, which had increased from 18 to 25 in the three preceding weeks, declined again to 21 last week, and included 11 in Glasgow, five in Greenock, and three in Aberdeen. The fatal cases of measles, which had been nine in each of the two preceding weeks, declined last week to seven, of which three were registered in Glasgow and two in Edinburgh. The deaths from diphtheria, which had declined from seven to three in the three preceding weeks, rose again to five last week and included two in Glasgow. The four fatal cases of scarlet fever showed a slight decline from recent weekly numbers, and included three in Glasgow. The deaths referred to different forms of "fever," which had been eight and five in the two preceding weeks, further declined last week to four, of which two (including the fatal cases of bubonic plague) were recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 82 and 58 in the two preceding weeks, rose again last week to 79, and showed an excess of 25 over the number in the corresponding period of last year. The causes of 25, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

## HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 21·2 and 27·0 per 1000 in the two preceding weeks, declined again to 26·7 during the week ending Sept. 1st. During the four weeks ending Saturday, Sept. 1st, the death-rate in the city averaged 24·5 per 1000, the rate during the same period being 19·8 in London and 16·0 in Edinburgh. The 179 deaths registered in Dublin during the week under notice showed a decrease of two from the number in the preceding week, and included 40 which were referred to the principal zymotic diseases, against numbers increasing from five to 33 in the five preceding weeks; of these 32 resulted from diarrhœa, four from whooping-cough, three from diphtheria, one from scarlet fever and from "fever," and not one either from small-pox or measles. These 40 deaths were equal to an annual rate of 6·0 per 1000, the zymotic death-rate during the same period being 5·3 in London and 2·2 in Edinburgh. The fatal cases of diarrhœa, which had increased from one to 25 during the seven preceding weeks, further rose to 32 during the week under notice. The cases of whooping-cough, which had been one and five in the two preceding weeks declined to four. The deaths from "fever," which had been three in each of the two preceding weeks, fell during the week under notice to one. The deaths referred to diphtheria, which numbered three, showed an increase, none having been registered in the two preceding weeks. The 179 deaths in Dublin included 52 of infants under one year of age and 30 of persons aged upwards of 60 years; the deaths of infants showing a decrease, and those of elderly persons an increase compared with those in the preceding week. Two inquest cases and two deaths from violence were recorded, and 58, or one-third, of the deaths occurred in public institutions. The causes of three, or nearly 2 per cent., of the deaths in the city were not certified.

The death-rate in Dublin, which had been 27·0 and 26·7 per 1000 in the two preceding weeks, further declined to 22·2 during the week ending Sept. 8th. During the past four weeks the death-rate in the city has averaged 24·3 per 1000, the rate during the same period being 19·2 in London and 15·6 in Edinburgh. The 149 deaths belonging to Dublin registered during the week under notice were 30 below the number in the preceding week and included 26 which were referred to the principal zymotic diseases, against 28, 33, and 40 in the three preceding weeks; of these, 20 resulted from diarrhœa, five from whooping-cough, one from "fever," and not one from either small-pox, measles, scarlet fever, or diphtheria. These 26 deaths were equal to an annual rate of 3·9 per 1000, the zymotic death-rate during the same period being 4·0 in London and 2·4 in Edinburgh. The deaths referred to diarrhœa, which had increased from nine to 32 during the five preceding weeks, declined again last week to 20. The fatal cases of whooping-cough, which had been five and four in the two preceding weeks, rose again to five last week. The 149 deaths in Dublin last week included 35 of infants under one year of age and 32 of persons aged upwards of 60 years; the deaths of infants showed a marked decline, while those of elderly persons slightly exceeded the number in the preceding week. Five inquest cases and four deaths from violence were registered, and 53, or more than a third, of the deaths occurred in public institutions. The causes of two, or 1·3 per cent., of the deaths in the city last week were not certified.

## VITAL STATISTICS OF LONDON DURING AUGUST, 1900.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in each of the 43 sanitary areas of London. With regard to the notified cases of infectious diseases in the metropolis, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 6·0 per 1000 of the population, estimated at 4,589,129 persons in the middle of the year. In the three preceding months the rates had been 7·2, 6·9, and 7·0 per 1000 respectively. The rates were considerably below the average in Chelsea, St. George Hanover-square, Westminster, St. Martin-in-the-Fields, Clerkenwell, and Wandsworth; while they showed the largest excess in Holborn, Whitechapel, St. George-in-the-East, Mile End Old Town, Poplar, St. Saviour Southwark, and Rotherhithe sanitary areas. Two small-pox cases were notified during August, both being in Wandsworth sanitary area; two small-pox patients were admitted into the Metropolitan Asylums Hospitals during the month, and two remained under treatment on Saturday, Sept 1st. The prevalence of scarlet fever showed a marked decline from that recorded in recent months; among the various sanitary areas this disease was proportionately most prevalent in Whitechapel, Mile End Old Town, St. Olave Southwark, Rotherhithe, Lewisham (excluding Penge), and Lee. The Metropolitan Asylums Hospitals contained 1657 scarlet fever patients at the end of August, against 1735, 1788, and 1804 at the end of the three preceding months; the weekly admissions averaged 152, against 198, 202, and 210 in the three preceding months. The prevalence of diphtheria showed a considerable decline from that recorded in the preceding month; the greatest proportional prevalence of this disease was shown in Whitechapel, St. George-in-the-East, Mile End Old Town, Poplar, St. Saviour Southwark, and Rotherhithe sanitary areas. There

* Including 12 cases of membranous croup.

† Including deaths from membranous croup.

were 1171 diphtheria patients in the Metropolitan Asylums Hospitals at the end of August, against 1402, 1212, and 1256 at the end of the three preceding months; the weekly admissions averaged 142, against 172, 151, and 183 in the three preceding months. The prevalence of enteric fever showed a marked increase over that recorded in recent months; among the various sanitary areas this disease was proportionally most prevalent in Stoke Newington, Bethnal Green, Mile End Old Town, Poplar, Bermondsey, and Battersea. The Metropolitan Asylums Hospitals contained 170 enteric fever patients at the end of August, against 176, 148, and 129 at the end of the three preceding months; the weekly admissions averaged 32, against 24, 21, and 20 in the three preceding months. Erysipelas was proportionally most prevalent in Holborn, Shoreditch, St. George-in-the-East, St. George Southwark, St. Olave Southwark, and Rotherhithe sanitary areas. The 17 cases of puerperal fever included three in Fulham, two in Kensington, and two in St. George-in-the East sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas of the metropolis, the deaths occurring in the public institutions of London having been distributed among the sanitary areas in which the patients had previously resided. During the five weeks ending Sept. 1st the deaths of 8532 persons belonging to London were registered, equal to an annual rate of 19·4 per 1000, against 16·6, 14·8, and 15·7 in the three preceding months. The lowest death-rates last month in the various sanitary areas were 8·5 in St. George Hanover-square, 10·5 in Hampstead and in Stoke Newington, 12·3 in Lee, 12·8 in Strand, and 14·1 in St. Giles; the highest rates were 26·1 in Holborn, 27·7 in St. Luke, 28·0 in St. Saviour Southwark, 29·2 in Limehouse, 30·6 in Woolwich, and 30·9 in St. George-in-the-East. During the five weeks of August 2236 deaths were referred to the principal zymotic diseases in London; of these, 107 resulted from measles, 30 from scarlet fever, 98 from diphtheria, 213 from whooping-cough, one from typhus, 41 from enteric fever, three from simple continued fever, and 1743 from diarrhœa. The lowest death-rates last month from these diseases occurred in St. George Hanover-square, St. James Westminster, Stoke Newington, St. Martin-in-the-Fields, Strand, and St. Olave Southwark sanitary areas; and the highest rates in City of London, Shoreditch, St. George-in-the-East, Poplar, St. George Southwark, and Woolwich. The 107 deaths from measles were only one-half of the average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in Holborn, Clerkenwell, St. George-in-the-East, Limehouse, St. Saviour Southwark, and Woolwich sanitary areas. The 30 fatal cases of scarlet fever showed a decline of 66 from the corrected average number; the greatest proportional mortality from this disease occurred in St. James's Westminster, Holborn, St. Luke, St. Olave Southwark, Rotherhithe, and Lewisham (excluding Penge) sanitary areas. The 98 deaths from diphtheria were 102 below the average number in the corresponding periods of the ten preceding years; among the various sanitary areas this disease was proportionally most fatal in Fulham, St. Martin-in-the-Fields, Whitechapel, Poplar, St. Saviour Southwark, and Rotherhithe. The 213 fatal cases of whooping-cough were 55 in excess of the corrected average number; this disease showed the highest proportional fatality in Stoke Newington, Limehouse, St. Saviour Southwark, Rotherhithe, Camberwell, and Plumstead sanitary areas. The 45 deaths referred to "fever" showed a decline of 14 from the average number in the corresponding periods of the ten preceding years; among the various sanitary areas the "fever" death-rate was highest in Chelsea, St. George Hanover-square, St. Pancras, Islington, Mile End Old Town, and Poplar. The 1743 fatal cases of diarrhœa were 427 in excess of the corrected average; this disease was proportionally most fatal in Hackney, Shoreditch, Limehouse, Poplar, St. George Southwark, and Woolwich sanitary areas. In conclusion, it may be stated that the aggregate mortality from these principal zymotic diseases in London during August was more than 9 per cent. above the average.

Infant mortality in London last month, measured by the proportion of deaths of children under one year of age to registered births, was equal to 282 per 1000. The lowest rates of infant mortality were recorded in St. George Hanover-square, Hampstead, Hackney, St. Martin-in-the-Fields, Strand, and St. Olave Southwark; and the highest rates in Limehouse, Poplar, St. Saviour Southwark, St. George Southwark, Rotherhithe, and Woolwich sanitary areas.

# THE SERVICES.

## ROYAL NAVY MEDICAL SERVICE.

THE following appointments are announced:—Staff Surgeons: J. F. Barry to the *Sappho;* J. H. Thomas to the *Devastation;* J. Acheson to the *Gladiator;* and G. H. Foott to the *Warspite* for the *Phaeton*. Surgeons: H. E. C. Fox to the *Gladiator* and B. F. Parish to the *Pelorus*.

## INDIA AND THE INDIAN MEDICAL SERVICES.

Captain K. V. Kukday will officiate as Civil Surgeon at Aden in addition to his own duties. The services of Major H. C. Hudson are replaced at the disposal of the Military Department. Captain A. R. S. Anderson is appointed to be Senior Medical Officer at Port Blair. The services of Captain J. M. Crawford, Captain J. S. S. Lumsden, Captain C. Milne, and Captain H. Austen Smith are replaced at the disposal of the Government of India, Home Department. Lieutenant-Colonel H. Allison and Major G. H. Fink have been granted furlough for one year. Major A. J. O'Hara has been appointed to act as District Medical and Sanitary Officer, Chingleput, during the employment of Captain G. G. Giffard on other duty. Captain R. G. Turner has assumed charge of the Civil Medical duties of the Tochi Valley. The following officers (under Civil Leave Rules) have been recalled to duty:—Lieutenant-Colonel G. S. A. Ranking, Lieutenant-Colonel J. W. Macnamara, Lieutenant-Colonel J. Lewtas, Lieutenant-Colonel T. Grainger, Lieutenant-Colonel R. N. Campbell, Lieutenant-Colonel B. Doyle, Lieutenant-Colonel G. W. P. Dennys, Lieutenant-Colonel S. J. Thomson, C.I.E., Lieutenant-Colonel E. S. Brander, Lieutenant-Colonel F. F. MacCartie, Lieutenant-Colonel W. A. Lee, Major G. F. W. Braide, Major F. C. Clarkson, Major E. C. Hare, Major C. N. Bensley, Major W. Vost, Major R. Shore, Major A. Coleman, Major D. G. Crawford, Major F. J. Drury, Major A. O. Evans, Major E. R. W. Carroll, Major W. G. Alpin, Major R. H. Castor, Major A. V. Anderson, Major B. B. Grayfoot, Captain H. B. Melville, Captain C. Duer, Captain J. Jackson, and Captain J. B. Smith.

Colonel C. A. Maunsell, R.A.M.C., the Principal Medical Officer of the Mhow District of the Indian Army, will retire shortly. He served with the Royal Artillery in the Bhootan campaign of 1864-65, and was present at the capture of Fort Buxa and the taking of the Bala Pass. He also served in the Egyptian war of 1882, and was awarded the medal and Khedive's star.

Captain H. Smith has taken over charge of the duties of Superintendent of Jullunder Jail. Lieutenant J. A. Dredge has made over charge of the duties of Superintendent of the Bannu Jail to Lieutenant F. V. O. Beit. Captain N. Rainier has assumed charge of the Civil Medical duties of Abbottabad, relieving Captain F. R. Ozzard. Lieutenant J. W. F. Rait has assumed charge of the Civil Medical duties of Kurram, relieving Lieutenant P. Atal. Captain P. St. Clair More has assumed charge of the Civil Medical duties of Kohat, relieving Captain J. Mulvany. Lieutenant-Colonel S. Little has resumed charge of the office of Civil Surgeon, Rawalpindi, relieving Major G. B. Irvine.

Miss V. Adams, M.B., C.M. Edin., has been appointed Assistant Superintendent of the Government Maternity Hospital, Madras.

## YEOMANRY CAVALRY.

Pembroke: Surgeon-Major G. R. T. Phillips to be Surgeon-Lieutenant-Colonel.

## VOLUNTEER CORPS.

*Royal Engineers* (Volunteers): 1st London: Surgeon-Lieutenant S. R. Dyer to be Surgeon-Captain. Submarine Miners: The Tees Division: Surgeon-Lieutenant J. W. Edwards to be Surgeon-Captain. *Rifle:* The Queen's Rifle Volunteer Brigade (Highland Battalion) Lothian Regiment (Royal Scots): Dr. James Mowat to be Surgeon-Lieutenant and Mr. John Cumming to be Surgeon-Lieutenant.

## TRANSVAAL WAR NOTES.

Major H. J. R. Moberly, R.A.M.C., Captain T. B. Beach, R.A.M.C., and Civil Surgeon Aymard lately prisoners of war, have arrived at Lorenzo Marques from Nooitgedacht, and will be sent to Durban.

Major Lawless, R.A.M.C., has been discharged from hospital to duty.

Dr. Howard Tooth has returned from South Africa after eight months' service with the Portland Hospital.

The hospital ship *Simla* has left Cape Town for England with Major W. B. C. Deeble, R.A.M.C., in charge of the sick and wounded, among whom were Major A. O. Fitzgerald, R.A.M.C., Captain Crawford, R.A.M.C., Lieutenant Croly, R.A.M.C., and Civil Surgeons W. B. Bennett and J. G. Willis.

The Welsh Hospital, now in Pretoria, has been increased from 150 to 200 beds.

The Imperial Yeomanry Branch Hospital at Maitland has about 70 patients.

Civil Surgeon J. Prestwick died from pneumonia on August 23rd at the General Hospital, Howick. Civil Surgeon H. A. Scott died from enteric fever at Pretoria on August 24th.

Lieutenant A. H. Benson, Militia Medical Staff Corps, has left Cape Town for England.

In an engagement near Warmbaths on Sept. 3rd, Mr. A. Cradock Fry, 9th Battalion Imperial Yeomanry, was taken prisoner while attending a wounded man.

### THE OPERATIONS IN CHINA.

Captain B. H. McCalla, of the United States vessel *Newark*, in a report to the United States Navy Department, wrote: "I beg also to suggest and ask that the following mentioned officers of the naval forces acting concurrently for the relief of the Legations in Peking be offered medals for aiding the United States force under my command and for supporting us in action, by reason of which our loss of killed and wounded was not greater." Captain McCalla's list includes the names of "Fleet-Surgeon Thomas M. Sibbald, R.N., and Surgeons Edward B. Pickthorn and Eric D. Macnamara, R.N., for skilful treatment of 25 wounded Americans, notwithstanding they had the care of a great number of their own wounded."

### DEATHS IN THE SERVICES.

Major George Hilliard, C.M.G., R.A.M.C., at the General Hospital, Newcastle, South Africa, on Sept. 7th, from a gunshot wound in the abdomen. He received his medical education at Trinity College, Dublin, where he graduated as M.B. and B.Ch. in 1885. He became Surgeon-Captain in 1887 and served with the Ashanti expedition under Sir Francis Scott in 1895–96, being awarded a star. He was promoted to be Major in February, 1899.

The Secretary of State for War has approved of revised regulations for the Army Nursing Service, which are to be taken into use at once.

# Correspondence.

**"Audi alteram partem."**

## "PROFESSIONAL ORGANISATIONS."

*To the Editors of* THE LANCET.

SIRS,—As the writer of the address which originated the present correspondence on this subject, perhaps I may be allowed to express my sympathy with Dr. James Ryley in his repugnance to any adoption by our profession of the methods of trade unions. I am convinced that such a course will alienate professional opinion and indefinitely delay the progress of reform. But while we cannot adopt the crude methods of the boycotter, it is necessary that we should have some means of bringing pressure to bear on those among us whose standard of ethics is so low as to be a source of injury and discredit to the whole body. It seems to me that the remedy lies in the education and elevation of the aforesaid professional opinion. The chief method of attaining this end is the encouragement by every possible means of local organisations. Every new-comer to a town or district should be informed that he is *expected* to become a member, and not to belong to the local society should stamp a man as an "outsider" in every sense of the word. Thus professional opinion could in every case be brought to bear on all disputed points. There should be an official code of ethics placed in the hands of every man on his qualification, and students should be taught that infringement of this code would prove an effective bar to an honourable career. At the same time no attempt should be made to obtain legal sanction for any such code. It was rightly said at the recent Paris Congress that "Deontology (the science of duty) has nothing to do with the civil law, which it entirely goes beyond." Also, "There are means of suppressing crime—these are punishments; there is another for correcting manners—this is example."

I am, Sirs, yours faithfully,

Sept. 10th, 1900. W. G. DICKINSON.

*To the Editors of* THE LANCET.

SIRS,—In reply to the letter of Mr. W. E. Wyllys in THE LANCET of Sept. 8th, p. 769, I wish to express my great pleasure that he agrees (although he does not say why) as to the desirability of a central representative body. I am delighted also to hear that the district committee of which he is the secretary are prepared to help the institute doctors in any really urgent case. This is to me quite a revelation, and contrasts curiously with the subjoined resolution and with the rejection by the committee of my own modest proposal. I have inquired carefully and cannot discover that an institute doctor has, under any circumstances, been met by any member of the district committee. But I am informed that when a member of the district committee was in despair over a bad case of post-partum hæmorrhage he accepted the aid of one of the institute doctors and rewarded the latter by cutting him (figuratively) the following day. To justify my own position I quote, precisely, the resolution of the district committee, passed unanimously at the annual meeting on Jan. 29th, 1897—a resolution never modified, never rescinded, and still in force:—

> That this district committee of the I.M.P.A. holds that those medical men who accept the posts of surgeons to the Great Yarmouth Friendly Societies Institute (considering the circumstances under which it was established) are acting in contravention of the rules and ethics of the profession; and therefore no member of this district committee can meet such surgeons in consultation, or hold any professional intercourse with them. Further, that medical practitioners in the town and neighbourhood (whether members or non-members of the committee) who do consult with institute surgeons are, in an equal degree, acting against the ethics of the profession, and accordingly members of the district committee *must*, under their rules and by-laws, refuse to meet such practitioners in consultation, or to have professional intercourse with them in any way whatever.

It is interesting to note how the field of vision of the medical eye, from its centre to its periphery, is filled with the wicked institute surgeon and how entirely the patient is ignored—no room for him whatever. I was not the only absentee from the meeting, for the resolution was passed by an oligarchy of six. I have had the temerity of making the following atrocious proposition:—

> That we meet institute doctors in consultation in the case of men properly belonging to clubs who are dangerously ill, and urgently, so far as can be ascertained, in need of further advice.

I have just received a note from Messrs. Moxon and Wyllys (president and secretary respectively) that it is "the resolution of the district committee to adhere to its position and consequently to reject your proposal." Very curious for persons who are prepared to help the institute surgeons, &c., is it not? Why, Sirs, my proposal is simply common humanity, and no threats of ostracism or of boycotting from the district committee shall persuade or frighten me to depart from it. *Re* London consultants, Mr. Wyllys denies my statement. Surely it is due to me to do more than this and to explain, as secretary, what is the attitude of the district committee towards these gentlemen. I press for a reply on this point.

On the subject of boycotting I have permission to quote the following letter I lately received from a much-esteemed consultant, whose aid we G.P.'s of Yarmouth are frequently invoking:—

> My personal feelings quite agree with yours. I have long felt that such trades-unionism ill becomes a profession which is supposed to consist of educated gentlemen and that *the only effect*, so far as I can see, is to reduce in the eyes of the lay public what ought to be a noble profession to the status of a trade. This boycott has the effect (and there is no use shutting our eyes to the fact) of lowering the social status of the profession in the view of the educated public—a thing which we must all deeply deplore, and which I fear will in the future help to deter the *better* class of the youth of to-day electing to choose medicine as an honourable profession.

As I am a very busy man medically and municipally, with little time to spare, I hope, Sirs, this is the last communication I may have to make to your columns on "Professional Organisations." With many thanks for your editorial comments, I remain, Sirs, yours faithfully,

JAMES RYLEY, M.D. Lond.

Great Yarmouth, Sept. 10th, 1900.

## "THE COVENTRY DISPENSARY."

*To the Editors of* THE LANCET.

SIRS,—I hope the profession in Coventry does not endorse the language of Dr. Richardson Rice when he says that he will give "the consultants of Birmingham an opportunity of deciding whether in the future they are prepared to uphold the honour of the profession or the interests of their pockets." May we put aside for the moment the honour of the profession, which does not appear to be in question, and remember that this is a matter of pounds, shillings, and pence, in which a section of the medical profession of Birmingham is to be asked to make a definite pecuniary sacrifice in order to help the profession in Coventry to raise their fees? I have already stated that I have every belief in the willingness of the medical profession in Birmingham to give the most careful consideration to any application coming to us from the profession in Coventry, but language of this sort does not help matters. It makes one wonder whether the failure hitherto experienced by the profession in Coventry to obtain the desired changes in the organisation of the dispensary may not have been due to this unconciliatory, indeed I might say the discourteous and quarrelsome, temper displayed by those who unfortunately are put forward as their spokesmen. There are many men in the profession who urge with incontrovertible truth that no boycotting resolution would justify a refusal to render assistance in an urgent case and therefore there is always a loophole by which those who do not wish to be bound by it may escape. If the scheme is to succeed there must be a strong unanimous feeling that the reforms asked for are wise, moderate, and just and that those who ask for them are animated by a genuine desire for reform and not by animus against an institution or the persons connected with it. I am, Sirs, yours faithfully,

Birmingham, Sept. 11th. ROBERT SAUNDBY.

*To the Editors of* THE LANCET.

SIRS,—I should not have troubled you further, but Dr. Saundby speaks of my letter as being uncandid and unfair and as causing him irritation. I have no quarrel with Dr. Saundby and certainly should not like to be unfair to him, but I should like to remind him that at Ipswich he asked "why the men came to the meeting year after year howling at the Coventry Dispensary," and if he can reconcile such a statement with rendering assistance to the cause of reform in Coventry I shall have nothing more to add. My letter in THE LANCET of August 25th has fully explained the situation, and as all the statements are accurate I cannot do more than supply the facts. Dr. Saundby was appealed to, as I have stated, to support the profession in Coventry, and we who laid the case before him were representing the majority of medical men practising in the town.

Does Dr. Saundby wish your readers to understand that he usually acts in a dual capacity, one as President of the Council of the British Medical Association and the other as a consulting physician of Birmingham—in the former position supporting the profession against a condemned institution, and in the latter supporting the institution against the profession? Surely the fact of his being approached as the President of the Council should not lead him to suppose that he was not acting as one of the profession in Birmingham.

In conclusion, I quite agree with Dr. Saundby that false charges would not hasten the cause of reform which Coventry seeks to apply to its professional life, but a thorough mastery of the facts by him would in all probability bring this discussion to a close. I am, Sirs, your faithfully,

Coventry, Sept. 11th, 1900. EDWARD PHILLIPS.

*To the Editors of* THE LANCET.

SIRS,—I have read with considerable interest the letters upon the Coventry Dispensary and I do not wish to further prolong the discussion, as I think I observe in Dr. Saundby's recent letters to the journals a desire to aid the profession in stamping out these degrading conditions of unjust and uncalled-for medical aid regulated by a lay element which totally disregards the advice and counsel of its medical officers. The Coventry Dispensary is entirely under the control of a committee of men who have so much confidence in themselves and in the management of that which seems to be the business and training of a medical man that they not only have sole charge of the finance, but exercise their prerogative as to how these medical men must carry on their profession.

The real reason of this terrible condition of things is this, that this institution has grown so large that even at the rate of nearly one farthing per head per week, which is about the sum paid to the medical officers, the return in the aggregate amounts to something over £300 a year to each medical man, and the certainty of this substantial sum overrules the professional instincts expected to be found in those belonging to so learned and honourable a calling. Nevertheless, I do hope that by the assistance of the heads of the profession, and of those who should set an example by action or by advice, the day will come when the medical men of the Coventry Dispensary will return to the fold of that great body of registered practitioners who, from their liberal education and the oath of allegiance to their *alma mater*, should do all such matters and things to the honour of the noble calling to which they belong.

I am, Sirs, yours faithfully,

CHARLES WEBB ILIFFE,
Coroner, North Warwickshire.

Willenhall, Coventry, Sept. 11th, 1900.

## "THE CAUSE OF CARIES OF THE TEETH."

*To the Editors of* THE LANCET.

SIRS,—I have followed with much interest the correspondence in THE LANCET on the above subject. I fully agree, on general biological grounds, with the views of the writers who hold that disuse or imperfect use of the jaws during growth tends to lead to the faulty condition of jaws and teeth so frequently met with in the newer generations of civilised men, and of those who have recently come under the influence of civilisation. In my opinion the condition, as far as the jaws are concerned, is one of "imperfect evolution" and "stunted growth" rather than of "atrophy"—which latter term implies a previous normal condition in the individual affected. I also subscribe to the view that disuse of the teeth tends to their deterioration and degeneration prematurely. But this, as are most etiological problems, is a complex one. I beg to be permitted to bring to the notice of those who are working at the elucidation of this subject, as well as your readers generally, a paper read by me before the Odontological Society of Great Britain (and published in the Transactions of that society in January, 1890), entitled, "Nasal Obstruction and Mouth Breathing as Factors in the Etiology of Caries of the Teeth and in the Development of the Vaulted Palate." In this paper I claimed for these factors an important share in the production of caries and vaulted palate, but the paper appears to have escaped the notice of recent writers on the subject. Ten years' further experience has only added strength to my conviction that in nasal obstruction and mouth-breathing we have an even more powerful and more common factor in producing these abnormalities than in the character or mode of preparation of the food.

I am, Sirs, yours faithfully,

SCANES SPICER, M.D., B.Sc. Lond.

Welbeck-street, W., Sept. 12th, 1900.

*To the Editors of* THE LANCET.

SIRS,—You have kindly published a letter of mine in THE LANCET of Sept. 8th suggesting that the removal of the wheat-germs from the flour by roller-milling causes defective teeth owing to mal-nutrition. As I wish to keep the two points—defective teeth and caries of the teeth—as far as possible distinct, it is hoped you will excuse me again addressing you. As is mentioned in the report of the Decay of Teeth Committee of the British Medical Association the mouths of men working in flour-mills invariably present extensive decalcification of the enamel and dentine. In milling 2 per cent. loss by waste is reckoned in converting wheat into flour. Much of this waste floats in the air, and the men working in the mill are likely to have a proportion of unfermented wheaten starch in the mouth, and, owing to the action of the saliva, an almost continuous supply of lactic acid bathing their teeth. When the wheat-germs are in the flour a proportion of the starch is converted into grape-sugar during baking, and thus lactic acid is evolved while the bread is in the oven; instead of, as when there is no diastase in the flour, being evolved in the

mouth to decay the teeth. Thus if the wheat-germs are removed, as in roller-milling, a greater amount of fermentation takes place in the mouth and a large amount of lactic acid is formed there to cause caries of the teeth.

The sub-committee of the British Dental Association, which some years ago examined the teeth of many school-children, reported that the children of certain low-class schools had better teeth than those of the high-class schools. I have suggested that this fact was due to the children of these low-class schools having been largely fed on contract bread such as is supplied to many unions. This contract bread contains wheat-germs which the roller-miller has removed while making the flour for his higher class customers. The earliest forms of mills, the old stone hand-mills, are still to be found in India, but are rapidly being replaced by gigantic roller-mills. I am informed that now the natives are commencing to have bad teeth. It appears that wherever the roller-mill is in operation carious teeth are found instead of the sound ones of the days of the stone-mill.

I am, Sirs, yours faithfully,

THOMAS G. READ, D.M.D. Harvard, L.D.S.R.C.S. Eng.

Cavendish-square, W., Sept. 8th, 1900.

## "A NOTE ON THE SAFEST METHOD OF REMOVAL OF THE APPENDIX."

*To the Editors of* THE LANCET.

SIRS,—I see in THE LANCET of August 4th, p. 328, in "A Note on the Safest Method of Removal of the Appendix," a curious statement connecting my name with a method of treating the stump in appendicectomy, which I have *never* followed. The writer says: "The continental method—that commonly followed by Terrier, Hartmann, and most Paris surgeons—is simply to ligature the inflamed and diseased appendix near its base, resect it with the thermo-cautery, cauterise the stump, and then let it fall back into the abdomen." I have never used it because it is my principle in abdominal surgery never to leave a stump in the abdominal cavity and never to consider an operation completed without perfect union of all peritoneal surfaces. Moreover, I never use the cautery in abdominal surgery. I cut the peritoneum and the muscular coats of the appendix, I ligate the mucous membrane, and I invaginate this very small stump in the parietes of the cæcum, placing a continuous Lembert suture on the external coats of the intestine, so that when the operation is finished infection from the stump is impossible.

I am, Sirs, yours faithfully,

Paris, Sept. 10th, 1900. DR. HARTMANN.

## "THE PRESENT POSITION OF PATHOLOGY IN ENGLAND."

*To the Editors of* THE LANCET.

SIRS,—The letter of Dr. C. Powell White in THE LANCET of Sept. 1st raises a subject of great interest to the public and the medical profession. It is true that clinical observation is invaluable and can never be replaced, but it is also a fact that diagnosis is increasingly being assisted by pathological methods, and disease prevented—e.g., rabies has been recently practically extinguished in this country by the application of a simple method suggested by pathology. Indeed, pathology has emerged from a pure to an applied science, as is evidenced by the multiplication of laboratories attached to hospitals and health departments in all countries. It is from the aspect of an applied science that many have to view pathology, including myself. Strange to say this application of scientific methods to medicine benefits the public and the profession as a body, but not the actual workers in pathology. Judging from an analogy in commerce—viz., the success of firms that employ scientific chemists at high fees—the policy is narrow. The labourer is worthy of his hire, why not the pathologist? It must be acknowledged that attempts are made to "sweat" pathologists and to belittle the work, for the attitude of the profession and the public in this country is somewhat behind the age. It savours of that past British disfavour of "scientific" methods as compared with "practical," which cannot, or will not, realise that action and thought can be combined successfully. In commerce we are learning this by some very rough lessons.

Now is the time ripe for the profession in this country to consider and determine the true value to set on the subject, and on the rewards of the pathologist (whether he practise it solely or associates it with clinical or state medicine) and so to mould public opinion. What valid reasons can be given for refusing to pathology the remuneration accorded to other special branches of medicine? None. Failing this due recognition what is the fate of such cheap work? In the end it deteriorates. The poorer classes should have facilities for pathological examinations as for other branches of medicine, and to this end committees of hospitals should assist this department in every way, and county or municipal authorities should provide health laboratories. As an assistance to the poor only are research associations of value, for by allowing the well-to-do to escape a just toll they damage the profession and indirectly the science in question. The reason that the status granted by many to the pathologist is not rendered by all, as Dr. Powell White says, is not clear; it appears to be connected with the degree of knowledge and courtesy of those with whom he has to deal. Therefore I venture to urge that the attention of pathologists, pathological societies, and the pathological committee of the British Medical Association should be actively directed to the matter, since it affects the medical and public welfare. I am, Sirs, your faithfully,

Plymouth, Sept. 8th, 1900. F. BUSHNELL, M.D.

## NEGATIVE SERUM REACTION IN A CASE OF TYPHOID FEVER COMPLICATED WITH LUNG TUBERCULOSIS.

*To the Editors of* THE LANCET.

SIRS,—The errors that exist in connexion with Widal's test as a means of diagnosing typhoid fever are few. Dr. Horton-Smith in his Goulstonian Lectures, as quoted in THE LANCET of April 14th, says that the estimate of 3 per cent. of failures in the agglutinizing power of the blood in undoubted cases of enteric fever is possibly a high one. Yet the fact that fallacies exist at all detracts from the value of the reaction as a feature to be absolutely relied on, and gives an element of uncertainty to those individual cases where the symptoms are anomalous and mistakes especially important to avoid. In the *Archives de Médecine et de Pharmacie Militaires* for January, 1900, a description was given of a case where typhoid fever in a tuberculous individual did not give the serum reaction, and in mentioning to your readers a somewhat similar case I do so in the hope that the attention of workers in the subject may be directed to other pathological conditions present with special relation to the effect they have on the serum reaction. The patient was a married woman, 36 years of age, whose family history was of a markedly tuberculous character. She had herself been treated for "consumption of the left lung" some six years ago, but had improved considerably since then. In March, 1899, however, an attack of hæmoptysis laid her up. When the case first came under my observation in December last complaint was made of general symptoms of a fever, which later proved to be typhoid fever. The typical rose-coloured rash appeared on the ninth day of the illness and successive crops of the papules came out until the eighteenth day. The abdomen had in the meanwhile become tender all over; it was fuller than normal; the spleen was enlarged; and soft watery stools were passed three or four times daily. The temperature rose gradually and the chart did not at any time show a greater morning remission than 2°. From the beginning a troublesome cough developed. The physical signs in the chest were those of a diffuse bronchitis with the exception, however, of a dull patch in the right apex where amphoric breathing and metallic râles could be detected. Sputum was brought up in large quantities with greenish masses and a great many nummular pieces. On the ninth day some blood was sent to the Clinical Research Association, from which body I received a report that it did not give the typhoid reaction. Two sharp attacks of hæmoptysis were noted during the illness, the first on the ninth and the next on the eighteenth day. In the fifth week improvement was noted in the abdominal symptoms; the temperature was lower by 2° and was distinctly not of a hectic type. The cough, however, persisted, keeping the patient awake at nights. By the seventh week all the abdominal symptoms disappeared but the pyrexia and cough persisted. About this time physical examination of the lungs showed signs of cavity at the right apex and some consolidation of a patch below the left clavicle. As it was

now considered that the activity of the lesion of the lungs was alone keeping up the pyrexia solid food was allowed. The appetite was extremely good. The patient has since improved greatly in health and at the time of writing (September) a fair amount of weight has been put on.

I am, Sirs, yours faithfully,

DAVID A. BELILIOS, M.R.C.S. Eng., L.R.C.P. Lond.

Wimbledon, S.W., Sept. 8th, 1900.

## "HALLUX RIGIDUS."

*To the Editors of* THE LANCET.

SIRS,—Both the letter of Mr. Lucy[1] and the article by Mr. Haward[2] to which it relates seem to ignore a surgical rule for which I have long contended in THE LANCET[3] and elsewhere; that whenever there is in the metatarso-phalangeal joint of the great toe irritation which is disproportionate to the degree of eversion, the great toe will be found to have been habitually packed *beneath* the second and that to set it free to resume the *position of rest* is the principal indication for treatment.

I am, Sirs, yours faithfully,

Gloucester, August 25th, 1900. T. S. ELLIS.

## "THE EXPECTANCY OF LIFE IN CASES OF CANCER OF THE BREAST."

*To the Editors of* THE LANCET.

SIRS,—I have been much interested in Mr. Barker's clinical lecture on the above subject published in THE LANCET of Sept. 8th. Such an accurate and careful analysis of cases as is there given is undoubtedly of the highest value. In one point, however, I think the statistics are defective in that it is not stated how many were cases of carcinoma of the right and left breast respectively. My reason for drawing attention to this omission is that my own clinical experience leads me to the opinion that the prognosis in cases of carcinoma of the right breast is not so favourable as that of the left *as regards the spread to internal organs*. I am inclined to think that inquiry will show that the liver is sooner and more frequently attacked in carcinoma of the *right* breast than that of the left. If this be so—and the arrangement of lymphatics favours it—then the expectancy of life in cases of cancer of the breast must be reckoned separately, and the two mammæ not placed on the same footing as is assumed now in all such statistics. This point of omission also characterises the valuable tables on the same subject published by Mr. Watson Cheyne. I have seen him since his return from South Africa, and he has kindly said that he will look into the matter.

I know that there is a difference of opinion amongst authorities as to which breast is most frequently attacked primarily by carcinoma. Mr. Roger Williams says that "nearly all statistics show that in women the left breast is more frequently affected than the right," while Mr. Marmaduke Sheild's cases at St. George's Hospital give only a slight preponderance in favour of the left mamma. Mr. Bryant, again, finds the proportion nearly equal, and Mr. Gross considers right mammary cancer to be more frequent than that of the left. Be that as it may, I am inclined to think that the expectancy of life is not so good in cancer of the right breast as in that of the left, owing to the greater liability to secondary involvement of the liver in the former case. As statistics like those of Mr. Barker might help to establish or refute this opinion I have ventured to draw attention to what I regard as an omission in them.

I am, Sirs, yours faithfully,

Glasgow, Sept. 8th, 1900. GEORGE THOMAS BEATSON.

## THE FUNCTION OF THE SYMPATHETIC AS A FACTOR IN ACUTE DISEASE.

*To the Editors of* THE LANCET.

SIRS,—In a recent article on Tachycardia following Enteric Fever,[4] while acknowledging my indebtedness to Surgeon-Captain P. C. Fenwick for his kind help in prosecuting the investigations on which the article in question was based, I stated that he had adduced a theory of sympathetic irritation underlying the symptoms I endeavoured to describe, which, however, I could not bring myself to accept as a cause of the rapid pulse rate and other features portrayed in my article.

Surgeon-Captain Fenwick has the courage of his convictions and has accordingly adduced his reasons in an article appearing in THE LANCET of August 11th (p. 402). I cannot help regretting that he appears to have fallen into the error so commonly pursued and, if I may so say without offence, so convenient to adopt when the difficulty of explaining an obscure nervous disease arises—to refer such trouble to the sympathetic nervous system. This tendency is by no means peculiar to himself. I have not infrequently noticed when no pathological lesion can possibly be suggested, and the functions of the heart are deranged, how customary it is to suggest that the symptoms should be referred to reflex action. This, after all, seems to be merely one way of begging the question, for the premiss equals the conclusion that the symptoms are the manifestations of functional disturbances of the organ which is controlled by the sympathetic, and therefore the sympathetic must be at fault. The suggestion of the reflex action is only a further instance of the same fallacy. It is with many of us, and far too much the habit of teachers and their followers, to seek everlastingly for some local and specific lesion to account for symptoms—to desire realism and to ignore the psychical element, to disregard the fact that after all the brain is the great centre, not only of control exercised over all actions, both voluntary and reflex, but in addition the receiver and sole interpreter of all impressions from without—that besides being the executive of the will it is also the throne of the intelligence.

Now in the study of disease and its symptoms such consideration should always present itself to the mind of every thoughtful physician, and if this is the case it seems to me that the first explanation of many functional disorders ought to be the psychical one. In my cases, with symptoms described as seen in the epidemic of enteric fever so prevalent in the army in South Africa, the fatiguing work and forced marching, worry, anxiety, poor food, and bad sanitation inseparable from such a campaign would all tend to demoralise the central nervous system, including both the mental processes and physical energies, to such a degree that any organ might be readily irritated and disturbed in its normal workings; and I would maintain that merely to refer these conditions to an affection of the sympathetic is wholly unsatisfactory. The irritable heart of the soldier of the American Civil War has often been written about, and is an illustration of the cardiac disturbance I have described. It is significant that these cases occurred without the intervention of acute disease and that the cardiac trouble was more frequently complained of by the civilian volunteers than by the militia, this fact being probably due to the more sensitive nervous system of the town-bred man.

I have only to add in conclusion that in lunatic asylums many curious vagaries of the heart and circulation are constantly observed without definite organic disease being discoverable. I am, Sirs, yours faithfully,

Sept. 10th, 1900. CHARLES BURLAND, M.D. Brux.

DRAINAGE OF COLWYN BAY.—The Urban District Council of Colwyn Bay has decided to re-sewer the whole of the district at an estimated cost of £45,000.

UNIVERSITY OF CAMBRIDGE.—Examination in Sanitary Science.—The order of examination for October is as follows:—*Part I.*—Tuesday, Oct. 2nd, 9 A.M. to 12 noon, in the Arts School, paper in hygiene; 2 to 6 P.M., in the Pathological Laboratory, practical bacteriology. Wednesday, Oct. 3rd, 9 A.M. to 12 noon, in the Arts School, paper in hygiene; 2 to 5 P.M., in the Chemical Laboratory, practical chemistry. Thursday, Oct. 4th, 9 to 10.30 A.M., in the Arts School, paper in bacteriology; 10.30 A.M. to 12 noon, in the Arts School, oral; 2 to 6 P.M., in the Physiological Laboratory, practical microscopy and oral. *Part II.*—Tuesday, Oct. 9th, 9 A.M. to 12 noon, in the Senate House, paper; 1.30 P.M., in the Senate House, practical and oral. Wednesday, Oct. 10th, 9 A.M. to 12 noon, in the Senate House, paper; 1.30 to 5 P.M., in the Senate House, practical and oral. Thursday, Oct. 11th, 10 A.M., in the Senate House, oral.

# THE TENTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

(FROM OUR SPECIAL CORRESPONDENT.)

## FIRST SECTION.

### TINNED MEATS.

CONSIDERING that the wars in South Africa and in China involve in different degrees and climes the great problem of feeding armies, the paper communicated to the First Section by Dr. L. VAILLARD, Professor at the Val de Grâce military school, is of practical interest at this moment. He dealt with the accidents that arise from the consumption of tinned meats. The process of tinning is simple and rapid. The meat is first boiled for about an hour. The broth is then separated from the meat and concentrated, so that when cold it forms a stiff jelly. Now this jelly and the boiled meat are placed together in tins and are hermetically closed by soldering, after which they are sterilised. The temperature for each sterilisation varies from 110° to 115° C. and the process generally takes an hour and a half. It is difficult to say what the effect of such food may be on the civil population, but with the army and navy there are good opportunities for precise observation. For instance, the French army consumes 3,000,000 tins annually and each tin contains the rations for five men. Thus we may say that 15,000,000 rations of tinned meat produced 201 cases of sickness in 1897 and 198 cases in 1898, resulting in only one death. The illnesses provoked can be divided into two distinct categories: firstly, various forms of indigestion occurring within from two to six hours after consuming the food and not accompanied by fever; secondly—and these are the majority of cases—the symptoms commence from 12 to 50 hours after the consumption of the tinned meat and thus follow on a period of incubation similar to that of diseases due to infective microbes; there is generally fever, the digestive troubles are more like those of gastro-enteritis, and sometimes there is blood in the evacuations. As for chemical poisoning, especially that due to lead, no symptoms indicating such accidents have been observed. Nor is there evidence to show that in course of time the meat preserved may deteriorate. Millions of tins are five and six years old before they are opened and the contents are eaten. Professor Vaillard argued that the toxic substance must have been contained within the meat itself and this might be the case if the animal had been overworked or was diseased when killed. It is then possible that though the living organisms may be killed by the process of sterilisation they may first produce poisonous conditions in the meat. It is also possible that delays, imperfection, or malpractices in the process of preservation may have introduced micro-organisms. In warm weather a few hours may suffice to deteriorate the meat. When this occurs attempts are sometimes made to sterilise this meat a second time so as to arrest the process of putrefaction. When the meat is bad the gas engendered causes the tin to bulge out, but even this can be to all appearances repaired. A very small hole is drilled in the tin, then the tin is exposed to heat again, the organic life which it contains is destroyed, and an invisible speck of soldering covers over the little hole. But if the living microbes are killed have they not produced poison during their lifetime that retains its toxic powers? Some of the meat examined contained such a number of dead cocci and bacilli as to bear all the appearance of an artificial culture broth. Are not chemical substances formed which are not affected by the sterilisation process? Nor is this always revealed by a bad odour. Some preserved meat that seemed good and sweet killed the guinea-pigs which were inoculated. But this does not prove that the meat would have the same effect when eaten. On the contrary that which killed when given as a subcutaneous injection was quite harmless when given as food. Experiments should be made with the preserved meats that have produced sickness, whenever any of it remains. Nevertheless this risk must not be exaggerated. Strict surveillance is needed to ensure that all the necessary precautions are adopted in tinning and that nothing but sound meat is employed.

### CHEMICALS AND THE PRESERVATION OF FOOD.

Bearing upon this question Dr. F. BORDAS, member of the French Consultative Committee of Hygiene, presented a report on the Use of Chemicals for the Preservation of Food. After describing the chemicals generally employed for this purpose, he urged that though some of them seemed to occasion no inconvenience the effect of others was open to doubt, and it might be said that, as a rule, any substance that could prevent fermentation must also interfere with the digestive process. Certain hygienists, such as Professor J. B. Bradbury, Dr. B. A. Whitelegge, and the late Sir B. W. Richardson, had suggested that when chemicals were employed the fact and the dose should be stated on the label. But it was objected that it would be impossible to control the dose. Nor could it be stated that a chemical was not injurious, for what might be eliminated easily by the young and healthy would be very injurious to elderly persons or to persons suffering from some kidney disease. If evil effects were not produced at once the constant absorption of such chemicals must in the long run be injurious. Therefore it was regrettable that any hygienists should have appeared to sanction their employment, and Dr. Bordas concluded by submitting a motion affirming that no antiseptics whatsoever, even if considered to be harmless, should be employed for the preservation of food.

During the portion of the discussion at which I was able to be present Dr. NEFLER and Dr. NOCARD were both absolutely opposed to the use of chemicals. The only safe preservatives were cold or heat; all others were mere methods of deception; they only served to preserve appearances, and the food which seemed wholesome was often poisonous. Dr. FOEDOR of Budapest agreed with this opinion, but Dr. FRAENKEL thought that the use of only certain chemicals should be forbidden. Non-toxic chemicals might sometimes be advantageously utilised. Dr. KIRSHNER and a French medical practitioner were of the same opinion. No vote was then taken, but at another sitting Dr. Bordas's motion was adopted, and it has been seen that this opinion of the section condemning the use of any chemical whatsoever for the preservation of alimentary substances was confirmed by the final and general meeting of the entire Congress.

## THIRD SECTION.

### THE WINDOW, THE ROOM, AND THE SUN.

One of the most distinguished of French sanitary reformers, M. EMILE TRÉLAT, presented a report to the Third Section on the Orientation and Mapping Out of Streets in Large Towns. No one has done more for domestic hygiene than M. Emile Trélat. As the founder of l'École Spéciale d'Architecture he was among the first to insist that architects should study sanitation. The most perfect systems of ventilation—such, for instance, as that of the Grand Opera at Vienna—have been carried out by his pupils in accordance with the principles which he taught. To his eloquence as a speaker and his facile style as a writer we owe the fact that the importance of a single and unilateral light in schools is so well appreciated on the continent, and he has also helped sanitary reformers to study and appreciate the marked effect produced by the porosity of walls in the ventilation of dwellings. These were the subjects of papers read by M. Emile Trélat at previous international congresses of hygiene, and now he insisted on the action of the direct rays of sunlight in preserving the health of urban populations. Unfortunately most towns and streets were built before any thought had been given to this factor. It was a curious fact that though so many religions were, in their origin, based on sun worship so little care had been taken to admit the rays of the sun within dwellings. Yet in the building of temples and churches this principle was observed, and by their orientation, the large windows being built east and west, the direct rays of the sun were brought upon the high altar. M. Emile Trélat pleaded that the dwelling-room should be placed in communication with the high heavens. Let the walls be pierced and the windows raised up to the ceiling, so that the rays of the sun might reach the farthermost wall. But he pointed out that the sky was not throughout equally beneficent. A distinction must be made between the light that descended from the zenith and that which came from the horizon. The first was a pure light, but as it descended vertically its vibrations could not penetrate through the windows. On the other hand, the light from the rising and setting sun travelled horizontally and could reach the farther ends of the rooms of the houses. But this light was not so pure; it had been somewhat deteriorated by passing through

prolonged layers of dust and vapours escaping from the soil. The intermediary light would therefore be the most useful for the interior of dwellings. This, the slanting light, as opposed to the vertical and the horizontal lights, was the light which should be introduced through the windows. Experience showed that it was at an angle of 30 degrees that we reached the mid-heavens, and to obtain this light houses should not be higher than two-thirds of the width of the street. Further, the height of a room should be equal to two-thirds of its depth. In other words, if the room was ten feet high the distance of the furthermost wall from the window should not be more than 15 feet and even in that case windows should reach the ceiling. This was not only necessary for the purification or natural disinfection of the interior of the room by the direct rays of sunlight, but also so as to prevent damp. A damp house was always unhealthy. The dampness from the soil could be avoided by building cellars under the house, by constructing a draining trench round the house, and by the use of a damp-proof course in the foundations, but it was not so easy to prevent the walls from becoming damp in consequence of rain and the humidity of the atmosphere. The wet might be excluded by impermeable paint or some other sort of coating, but this destroyed the porosity of the walls and therefore could not be recommended. The true remedy was thick walls and a good exposure to the sun. The heat of the sun would then dry the walls before the dampness had time to reach their interior surfaces. As in towns some shade must be thrown on the dwelling by the houses in front and behind, all that could be done was so to place these houses as to secure for them, not all the sun's rays, but the best rays and as much of them as possible. In temperate climates the conditions that prevailed in winter must be considered and calculations must be based upon the incidence of the sun's rays during the shortest day of the year. Then it was also necessary to take into account the direction of the streets. First those streets which were parallel with the meridian; when the sun was in the south they were well swept by its rays, but only for a short time. On the other hand, streets that were parallel with the equator would be constantly in the shade of the houses that faced them. Adolphe Vogt, taking the latitude from Vienna to Paris, had studied the purely geometrical problem—namely, what should be the height of the houses and the width of the streets so that the rooms on the ground floor should receive direct rays of sunlight in the winter. The result was that streets running from north to south should be twice and one-third as wide as the houses were high, while those that ran from east to west should be four times as wide as the houses were high. Even M. Trélat, who is an idealist, recognises that such conditions are impossible. Habitations so widely apart would cease to constitute a town, for the object of a town was concentration. But, nevertheless, this calculation might at least serve to show that every effort should be made to widen the streets and to avoid building lofty houses. M. Trélat concluded by urging that these principles were too often neglected by municipalities in spite of the improvements which had been effected in other directions.

In the short discussion that followed M. BECHMAN (the President of the section) lamented that the tendency in all large towns was, on the contrary, to build loftier and loftier houses. The section agreed to accept the conclusions of M. Trélat's report—namely, that it was the duty of sanitary reformers to seek to widen the streets and to prevent the building of tall houses.

### THE SMOKE NUISANCE.

Dr. ARMAND GAUTIER and Dr. NESTOR GRÉHAUT presented a report on the Pollution of the Atmosphere of Large Towns. Within the walls of Paris there were, they said, about 8000 hectares of land and on this surface some 3,000,000 tons of mineral fuel were burnt per annum. This made 375 tons per hectare, or about one ton per day per hectare, or again about 100 grammes of fuel per square metre. These 100 grammes contained about 70 grammes of pure carbon and should therefore yield in combustion 246 grammes or 125 litres of carbonic acid. Taking the chimneys at an average height of 20 metres and considering that in a still atmosphere the gas travelled up and down equally, a column 40 metres high and one metre square would contain 40,000 litres of air in which 125 litres of carbonic acid would be distributed, or nearly three cubic centimetres of carbonic acid per litre. As a matter of fact, however, according to the experiments of Boussigault and Lévy, the air of Paris only contained 31 volumes of carbonic acid per 100,000 volumes, and this was only three per 100,000 in excess of the quantity contained in pure air. Nor could this addition of three volumes of carbonic acid be attributed wholly to the fuel consumed, as there were many other agencies that produced this gas. M. Müntz and M. Aubin found that the atmosphere of Paris contained from 32·2 to 42·2 volumes of carbonic acid per 100,000 volumes in heavy cloudy weather and from 28·9 to 31 volumes in fine clear weather, and the proportion was 24 volumes in the very pure air at Cape Horn. The air within the earth of the Jardin des Plantes contained 24 times more carbonic acid than was usual in the atmosphere; therefore a part of the carbonic acid in the air came from the fermentations within the soil. The report then proceeded to deal with the very considerable proportion of carbon monoxide produced by gas, by stoves, fires, &c. But nevertheless the reporters concluded that the causes of insalubrity due to industrial or domestic chemical products of combustion were in most towns less dangerous than would at first sight appear likely. Though an immense amount of carbonic acid gas and carbon monoxide was produced, still there remained but feeble traces of them in the atmosphere of the large towns. These gases were very dangerous in certain localities within certain ill-ventilated buildings, but not so in the general atmosphere. Dr. Gautier and Dr. Gréhaut thought that the emanations from the soil were far more dangerous; the smoke at worst only acted by reason of its depressing effects and not as a direct poison.

### PERFECT COMBUSTION.

Dr. ZAHOR of Prague opened the discussion on this report. He reviewed the laws enacted in various countries so as to abolish smoke. To judge by the stringent nature of these enactments smoke should have long since vanished from the face of the earth. The French law forbade black and prolonged smoke; the English law which was more ancient only dealt with factories, but it inflicted a daily fine. Yet the chimneys still continued to smoke. In Bohemia the manufacturers were beginning to utilise smoke-consuming processes. Dr. Zahor felt convinced that smoke was very injurious. It caused darkness, it attracted rain, it prevented plants from growing, and it likewise lowered human vitality. It spoiled buildings, furniture, clothes, and property of all sorts. It injured the lungs, and produced nausea, headache, and all the symptoms of poisoning. To prove this it was only necessary to compare at a post-mortem examination the lungs of a person who lived in a town with those of a person residing in the country. It was not only the big factories but the small workshops and the domestic fires that contaminated the air.

Mr. ADOLPHE SMITH protested against the suggestion, sometimes lightly made, that smoke was not injurious. Parisians especially would have to be careful. Now that wood was so dear and the consumption of coal in private houses was increasing rapidly there was much more smoke in Paris; and even if this smoke was not particularly injurious in itself it became very mischievous when, mixing with a white mist, it produced a black fog; and the fogs in Paris were getting more and more like those in London. Whatever chemists might say about smoke, it was a fact that in London thick "pea-soup" fogs sent up the death-rate by leaps and bounds. As for the suggestions made that the law should insist on perfect combustion, what was perfect combustion? Theoretically, if perfectly consumed, a kilogramme of carbon should yield some 8080 calorics of heat, and produce no smoke whatsoever and no carbon monoxide. Practically a kilogramme of carbon yielded little more than 2470 calorics of heat, produced a quantity of black smoke and some carbon monoxide. Could anyone say where and how perfect combustion was produced for industrial or domestic purposes? The speaker had been privileged in making experiments with a stove that did realise the ideal of no smoke, no carbon monoxide, of perfect combustion; indeed, the combustion was so perfect that it not only melted platinum wire but consumed the stove as well. Thus a laboratory success proved a commercial failure, for no one would buy a stove which burnt itself up in a few weeks. The fact was that the problem still awaited a practical solution. They might reduce the volume of smoke but they did not know how to abolish it altogether. But the advantages of perfect combustion were so enormous from the sanitary, economical, and æsthetic points of view that every effort should be made to encourage research and inventions in this direction. The

State and the municipalities should give some impulse and facilities to such endeavours.

Dr. BERTHOT was not satisfied with the mere suppression of black smoke. He spoke of the grit or mineral particles which escaped with the white or invisible smoke or fumes and thought that where many habitations clustered round factories, which threw large quantities of such particles into the atmosphere the inhabitants would suffer from irritation and injury to the lungs.

Dr. ZAHOR had brought the matter forward in the Bohemian Diet and he was anxious to gather from the section some indication as to the recommendations which he should make to his Government.

M. BECHMANN, as President of the section, replied that the section was at least agreed that black smoke could be avoided and the law might interfere to prevent this nuisance.

The section then adjourned.

## THE FIRST AND THIRD SECTIONS UNITED.

### PATHOGENIC GERMS IN WATER AND IN THE SOIL.

On Thursday, August 16th, the First and Third Sections sat together in the big amphitheatre to discuss the question of water-supply. It was, as it were, a consultation, the engineers and architects seeking the advice of the bacteriologists. Dr. THOINOT and Dr. VAILLARD had presented a short report on the Presence of Pathogenic Germs in Water and in the Soil. Though such germs, it had been shown, did not live long in water, experience demonstrated that polluted water did provoke typhoid fever and cholera. In the laboratory natural conditions could not be perfectly reproduced. The typhoid bacilli died rapidly when placed in water in the laboratory, but they had been found living in water collected in the open and at various intervals, thus showing that outside they subsisted for a much longer time. According to Lösener, Remlinger, and Schneider for the typhoid bacilli, and various French and German authorities for cholera bacilli, these germs were to be found in the water-supply of populations suffering from these diseases and also in the water-supply of populations when no such epidemics prevailed. The reporters sought to explain away this flagrant contradiction by supposing that the population had been rendered immune by previous epidemics, an argument which did not take into account the instability of populations. A more plausible argument was the possibility of mistakes in observation. For these numerous bacilli, that were like the pathogenic types and yet offered some slight difference, more elaborate studies were necessary. Indeed, they were only on the threshold of such investigations. (This struck me as being a very important confession, particularly when coming from such eminent authorities. It suggests that innumerable mistakes have been committed, for the fact is acknowledged that water condemned by bacteriologists has been perfectly innocuous, while, on the other hand, it will be remembered that at Maidstone during the great typhoid fever epidemic the specific germ of this fever was not found in the water. The suggestion then was that the germ had been in the water, but that its presence had ceased by the time the water was examined. The epidemic, however, did not cease so promptly.) Dr. Vaillard and Dr. Thoinot attributed the contamination of the soil and of water to pollution from drains and cesspits. They did not believe that germs could live for long on the surface of the soil, but they might find more favourable conditions a little deeper down. Yet when Lösener examined the earth taken in close proximity to the buried bodies of persons who had died from typhoid fever and from cholera it appeared that these germs did not live more than a few weeks in the earth. But it was claimed that these experiments were not conclusive because the conditions of cemeteries varied greatly. In any case Gielt had shown that the bacillus of typhoid fever lived for five months, and for nine months in a heap of manure, and that when the earth was dug up in old parts of a town or at human guano works, epidemics of typhoid fever had ensued. It was therefore probable that soils formerly contaminated had retained for a long time infectious germs, and these could be carried to some distance by the water that traversed such soil. The earth was a natural reservoir for a great number of bacteria, especially the septic vibrio, the spores of tetanus, the pyocyanic bacillus, various pyogenic agents, the pneumococcus, &c. Lösener found the bacillus of typhoid fever deep down in the earth of a field where there was no evidence of contamination. On the other hand, in soil which had been artificially contaminated the bacteria had entirely disappeared. Remlinger and Schneider examined 13 specimens of earth collected in Paris and seven seemed to contain the germs of typhoid fever. Therefore there was something to be said for the theory that the germ of typhoid fever might exist elsewhere than in the body and in the dejecta of patients suffering from typhoid fever. If, then, such germs sometimes existed naturally in the soil and were not always the result of a specific contamination of this soil, the water gathered from such a district might communicate the disease to those who drank it. The water and the earth by themselves, and not a human contamination, might cause epidemics of typhoid fever and cholera. Otherwise, how should the presence of the cholera microbes in the water of rivers at certain seasons and periods in localities where there were no cases of cholera be explained? The same observations had been made with regard to the germ of typhoid fever. The report concluded that the study of the soil and its microbes needed much greater attention than had as yet been given to the subject.

### SHOULD ALL DRINKING-WATER BE STERILISED?

It was in the face of this most perplexing report that the discussion of the joint sections began and it was quite pathetic to witness the sanitary engineers rise from their places one after the other, and appeal to the bacteriologists for some clear and distinct instructions as to what should or should not be done. Then there was also the question of the presence in water of bacteria other than the well-known pathogenic germs. Dr. A. J. MARTIN insisted that it was important to note the number of bacteria of whatever species and he seemed to think that it was a great advantage to reduce their number; but another speaker protested that he had studied the bacteria in the human mouth. These were various in race and plentiful in number. Would it be wise when the mouth seemed to need so many bacteria to extract them all from the water which they drank? The sterilisation of water might not be an unmixed blessing, for ferments were needed to digest food. A German delegate asked that a commission should be appointed, but Professor FOEDOR of Budapest, who presided over the First Section, objected that the processes for the bacteriological analysis of water varied from day to day. It was generally agreed that such analyses were indispensable and the sections desired that the process of analyses should be the same in all countries, and though this end was not likely to be attained at present, still an international commission to study the question would render great service. A resolution in favour of creating such a commission was then carried unanimously.

M. LAUNEY, as a civil engineer, now asked whether or not all life was to be suppressed in the water supplied for drinking purposes, or was it, on the contrary, better for digestive purposes to leave certain inoffensive microbes. The intestines of a newly-born infant possessed no bacteria; but when the infant had lived twenty-four hours they contained many microbes and notably the bacterium coli and yet the infant could not at that age be accused of drinking Seine water. Who was capable, clamoured the engineers, of deciding which were the injurious microbes? Water-supplies were looked upon with great suspicion because they contained the bacterium coli, but this self-same microbe abounded in the intestines of perfectly healthy men and women. Might it not be said that what existed in a healthy man could without injury remain in water? Nor was it possible to get an instrument which would be a terror to the bad and a saviour of the good. Simon de Montfort, during the Crusades, captured a town and being asked what should be done as all the inhabitants were not heretics but some of them good Christians, replied, "Massacre them all and God will recognise His own." Were they to treat the organic life existing in water in the same manner?

Dr. CALMETTE, of the Pasteur Institute at Lille, seemed to be of this opinion. He said that spring water might be very pure, but they could not be certain that it would remain pure. The more civilisation spread the greater was the tendency to pollute natural springs or water intakes. Nor could they reckon on water from the chalk remaining pure. Fissures might occur at any time in the chalk. Therefore they had better abandon the costly expedient of bringing to town from a great distance waters supposed to be pure. Let them, on the contrary, take whatever water might be close at hand whether pure or not, but let them see that it was thoroughly sterilised. For this there were two processes available, the chloride-peroxide and the ozone processes. The former was

difficult to manage and might attack the lead in the pipes and thus produce another and chemical source of poisoning. As for the sand filtering process it always let some microbes through. Ozone did not bring foreign matter to the water. It acted just as nature acted. They could have sterilised water, they could make sure that it was sterilised, but they could never be sure that a water supposed to be pure would remain pure.

M. BECHMANN, President of the Third Section, objected that the processes of sterilisation were only just becoming known. They had not been fully studied. In this very early stage of their knowledge of the subject they could not rush wildly into expenses that would involve millions of the public money. The only thing practicable was to express an opinion that more effective measures should be taken to protect the water intakes or gathering grounds.

Dr. FRAENKEL, a German delegate, argued that unless they found conditions enabling them to multiply the bacteria would die. Experiments made at Berlin with the bacilli of cholera and typhoid fever showed that they could not multiply when at a depth of two and a half or three metres from the surface of the ground. It was only the superficial layers of the soil that could contaminate the water that passed through it. Germs would not be found in the lower strata.

Now it was M. DE MONTRICHER, engineer from Marseilles, who rose and challenged the bacteriologists once more to say whether or not all bacteria were injurious. Professor FOEDOR replied that there were excellent waters which did contain microbes.

M. BARBIER (Lille) explained that an official commission had recognised the merits of the ozone process. In his house all the water was ozonised. At the Lille Pasteur Institute everyone drank ozonised water. When this water was distributed it no longer contained any ozone as ozone was extremely volatile. Fish lived well in this water. Dr. LOEFFLER, speaking in German, said they had all been taught that a sand filter was a sufficient guarantee. Chalk soil was dangerous for they never could tell when or where a fissure might occur. Therefore he preferred sterilisation. Professor POISSEL explained that all water-supplies were strictly controlled in Germany. Dr. LEMBOURG inquired whether the manufacture of ozone might not be subject to interruptions and, just as in the case of filtrations, accidents occur. Dr. GRETLER explained that at Stoltz and other places what were called springs were simply rivers emerging from the ground. Under these circumstances some bacteria might travel from three to five miles. The ozone process was good and so were the sand filters.

The PRESIDENT of the First Section here remarked that M. Launey in his report submitted to the Third Section had said that when the death-rate for three years had reached the figure of 22 per 1000 per annum the Government should insist on an investigation being held. The President thought it was too long to wait for three years.

M. LAUNEY replied that limiting the delay to three years was better than no limit, but this was a local matter of detail. His report was not a resolution but a summary of facts. He had not attempted to dogmatise, but had only sought to interrogate, and the numerous criticisms which had resulted were precisely what he wanted to call forth. Dr. Henriot of the Academy of Medicine had said that they should always use sterilised water. This was the Simon de Montfort policy and it was an unjust policy. They could not call upon the municipalities to spend large sums of money to destroy that which had not been proved to be injurious. They must, on the contrary, strive to obtain the maximum of security with the minimum of expense.

The resolution which the Third Section had carried was now put to the joint sections. To this demand that more efficacious measures should be taken to prevent the pollution of rivers and to protect water intakes Dr. CALMETTE moved an addendum engaging municipalities whose water-supply is not above suspicion to sterilise such water without, however, introducing foreign chemical substances for that purpose.

M. BECHMANN expostulated that we must be careful that in practice sterilisation did not mean the substitution of one poison for another.

Dr. CALMETTE protested that he did not advocate any special apparatus, and the two sections not only carried the resolution, but agreed generally that where the water was of doubtful quality it should sterilised.

Thus terminated a somewhat remarkable debate, for it had at least served to display the barrenness of the land. The bacteriologists who were to enlighten and instruct the engineers showed themselves to be doubtful on almost every practical point raised. It is hard to say what an engineer should do if called upon to devise a scheme of water-supply in the face of this debate. Some bacteriologists urge that the bacteria in water are harmless; some hint forcibly that even the pathogenic germ itself may not be pathogenic after all, that bacteria of some sort—they do not say what sort—are useful for the digestion, and that the bacterium coli is almost symbolical of health. Others naturally hold that its presence in water is most menacing. One party declares that sand filters or purification by the action of the soil are most efficacious, or that spring waters are the best. Then come other speakers who condemn such springs because they are but channels for carrying germs many miles; while we are also told that cholera and typhoid fever germs abound in rivers when there are no cholera and no typhoid fever in the land. Then just as the attentive listener might be tempted to think that the danger has been greatly exaggerated and that we need not trouble much about these living organisms in the water we drink, we are informed with all the authority that attaches itself to a well-known Pasteur Institute that no water whatsoever is safe and that all waters must be sterilised. If to the confusion arising from all these contradictions we add that many speakers, as noted above, insisted in speaking in German though most of them could have spoken in French and though but few persons present understood German, it will readily be gathered that the engineers who were thirsting for knowledge and precise instructions went empty away.

*(To be continued.)*

## NOTES FROM INDIA.

**(FROM OUR SPECIAL CORRESPONDENT.)**

*The Increase of Plague.—The Extraordinary Mortality in Bombay City.—The Pasteur Institute.—Punishment for the Cawnpore Plague Rioters.*

As anticipated the plague mortality is increasing. There were 449 deaths in India last week as compared with 285 in the previous seven days. The increase has been chiefly in Mysore which reports 210 deaths. There was an increase also in Calcutta which returned 103 deaths, but 27 of these appear from the local returns to have been "suspected" deaths. Bombay city recorded 51 deaths and the districts recorded 64. The general mortality of Calcutta was at the rate of 41·2 per 1000 as compared with the five years' average of 27 4 per 1000. The plague and "suspected" cases do not account for the increase and there is a balance of excess not explained in the returns. It is a question whether there is not more plague than is supposed. Inquiry of the medical staff discovers the curious fact that very few of the cases occurring at the present time showed buboes. Another curious observation is that comparatively few living cases are reported. All through the outbreak there have been discovered a certain proportion of living cases, but this proportion has sunk of late to a very low percentage. It is difficult to give an explanation of these two variations.

The general mortality of Bombay in the absence of recorded plague is remarkable. There were 2203 deaths from all causes for the week ending August 21st—an increase of 621 over the previous week. The rate is no less than 139 per 1000 per annum. The deaths from cholera were 770, but this high figure leaves 1433 deaths as compared with an average weekly mortality of about 600. There were only 64 deaths returned as due to plague. However far these official returns of plague may be below the mark it is evident that plague shows no sign of recrudescence. A curious feature in the Bombay figures is the extraordinary increase in the number of deaths attributed to phthisis. That this mortality should be double the average rate is absurd and shows the worthlessness of the returns.

Cholera is very prevalent throughout India. It is again on the increase in cantonments and the following regiments are more or less sufferers. The 2nd York and Lancashire Regiment, 19th Bengal Lancers, Royal Inniskillings, 4th Bombay Rifles, 1st Royal Fusiliers, 1st Cheshire, 11th Madras Infantry, 4th Hussars, 3rd Madras Lancers, and 28th Punjab Infantry. The totals are 232 cases and 138 deaths.

The Pasteur Institute at Kasauli is evidently meeting a great want. On August 17th 28 persons were undergoing

treatment; of these two were British officers, 17 were British soldiers, and there were two native soldiers, two European civilians, and five native civilians.

The lengthy trial of those accused of participation in the murders of the police constables during the late Cawnpore plague riots has concluded with the conviction of all the principal prisoners. One prisoner was brother to one of the municipal commissioners and his action in fomenting the outbreak seems to have been largely due to the loss of a municipal contract. There was a sensational scene outside the courthouse, the crowd raising loud lamentations. 20 prisoners were sentenced to death. These plague riots were particularly vicious and the lawless element in Cawnpore has long required a severe lesson. It is to be hoped that the Government will not alter the sentences.

August 23rd.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

*Report by the Public Health Committee of the Edinburgh Town Council on the Prevention of Consumption.*

IN October, 1898, the Edinburgh Town Council remitted to the Public Health Committee to consider whether any and what steps should be taken by the local authority to protect the public in Edinburgh against consumption, and to report. The report of the Public Health Committee has now been published. This report has been prepared with great care and with the utmost regard to the opinions of the medical profession. Before any practical suggestions are made various general questions with regard to pulmonary consumption are fully discussed, the report forming an excellent treatise on the nature, the extent, distribution, communicability, prevention, and general treatment of consumption. A strong contrast is drawn between the present outlook as regards the treatment and prevention of consumption and the attitude of men's minds towards the problem 20 or 30 years ago. Now the question is full of hope, while in those days the French aphorism was being continually illustrated: "Consumption is a disease from which the rich are sometimes cured—the poor never."

The report begins by showing how little was known as to the real nature of tuberculosis until the discovery by Professor Robert Koch of the bacillus of tubercle. Men had before that, to some extent, realised the importance of hygienic conditions in the treatment of the disease, and Villemin in 1865 had proved the infectivity of the sputum, but no distinct progress was made until the cause of the disease was discovered. Regarding the organism the following points are noted. 1. The organism is the sole and only cause of consumption in whatever form the disease appears. "No bacillus, no consumption," is now an axiom. 2. It belongs not only to man but to the lower animals. 3. It comes from without and does not arise in the body. 4. The tubercle bacillus does not originate in nature outside the animal organism and the only natural places for its growth are the bodies of certain animals. 5. The organism is one that thrives in the dark and at the usual temperature of the human body. All conditions which bring about a low state of the human health, such as bad air, dark dwellings, intemperate habits, poor food, and habits of uncleanliness are favourable to the growth of the bacillus. 6. It multiplies by subdividing itself and in the early stages of the disease it multiplies very slowly. 7. Though the bacillus cannot multiply outside the body, yet it can live even in a dried condition. 8. There are degrees of virulence in the bacilli. 9. The tubercle bacillus is not inherited. This last fact must be regarded as good tidings to humanity, for if consumption be a preventable disease and not hereditary the spread of the disease may have a powerful check put upon it. There has been a great diminution in the extent of the ravages made by the disease during the last 50 years, but even at the present time Europe alone is yielding more than 1,000,000 victims per year. Tables are inserted in the report to show the distribution of the disease in Europe. Russia has the highest mortality, Austria comes next, and then France, while Germany, Sweden, and Ireland take the next place. Norway, Denmark, Scotland, the Netherlands, and Italy stand together as almost the least affected, while England and Wales take the first place with the lowest mortality. Neither poverty alone nor poverty combined with severity of climate is necessarily a cause for consumption, for in the United Kingdom the province of Connaught, the Hebrides, and the wilds of Ross and Sutherland suffer as little from consumption as the southern counties of England. The provinces of Ulster and Leinster suffer more than any other section of the United Kingdom. From the tables it is also seen that the annual death-rate per 100,000 persons is 173 from consumption and 317 from inflammatory diseases of the breathing organs; total, 490. In Ireland the figures are 203 from consumption and 277 from inflammatory respiratory diseases, the total being 480, while in England and Wales the figures are respectively 135 and 315; total, 450. The figures for Edinburgh are 191 and 331; total 522. The average for the United Kingdom is 170 and 303; total 473.

There is now a great accumulation of proof that consumption is infectious and that there are many ways by which it can be conveyed to man. Transmission from parent to child, which formerly was believed to be the only mode of infection, is now known to be of exceedingly rare occurrence. Certain persons, however, show a more or less strong disposition to succumb to the invasion of the organism just as certain persons are more liable to be attacked by the infectious fevers. Turning to the question of the preventability of consumption the committee again emphasise as a truth to be written in letters of gold that consumption is not hereditary and points out the highly significant fact that no chronic malady is so much influenced by the application of sanitary measures. From the tables compiled by Dr. Arthur Ransome, which are given in the report, it is seen that while in the year 1838—the first year of Her Majesty's reign—the death-rate from consumption per 100,000 of the population was 38, by the year 1894 this death-rate had been reduced to 14. The only cause of this change was the inbringing of healthier conditions of common life. The Queen's reign had been a period of reform. The poorer classes had benefited much by the Factory Acts and the repeal of the Corn Laws, the dawn of sanitary practice appeared, and the blessings of fresh air, sunshine, and cleanliness began to be sought after. If within the past 60 years consumption has been reduced by nearly two-thirds by the ordinary development of improved sanitary measures, the disease may in the next century become as rare as small-pox or leprosy as the result of means taken directly to combat the evil. In Germany until a short time ago there were few consumptive sanatoria, but since the formation four or five years ago of the National Union for Combating Tuberculosis sanatoria have grown up in the neighbourhood of every considerable German town. At present there is one in the course of erection in Berlin which will receive as many as 1500 patients. As regards a protective serum, so far no substance has been found which is of much use in the human subject, although the last tuberculin produced by Professor Koch is highly useful as a test for cattle, and therefore is an important means of prophylaxis for human beings. The report goes on to explain the principles of the open-air treatment of consumption and shows that for the cure of consumption high altitudes and warm climates are not necessary, as was once thought to be the case. The hope is expressed that those who have the means to give will be stimulated by the work done in the Victoria Hospital in Edinburgh and at Mr. Quarrier's Consumptives' Homes at Bridge of Weir, to increase the means, which at present are small, for the treatment of cases which are still in the stage at which the cure is possible.

As regards the duties of municipalities towards the extirpation of consumption the report recommends the following as necessary steps: (1) the devising of means to inform the public regarding the origin of consumption and its main characteristics; (2) the adoption of a satisfactory method of disinfection of houses in which cases have occurred; and (3) the encouragement of the public to take the earliest note of the earliest signs of consumption and to call in a medical man who may in any suspected case obtain a bacteriological report on whether the patient is or is not tuberculous. These three propositions are in operation in Edinburgh and the committee does not see the necessity of introducing compulsory notification in this city. They are of opinion that as places and means of treatment become available sufferers will readily come forward for relief. The committee have come to the conclusion that one special duty is incumbent on the municipal authorities—namely, to devise means of dealing with cases in the last stages of the disease which are to be found in houses of inadequate accommodation. The mortality has been found to be highest

where bad sanitation is most pronounced. The sanitary condition of the city is being steadily improved and matters are consequently much better than they were, but of the persons who died from consumption in Edinburgh last year three-fifths inhabited houses of one, two, or three rooms, the house in no case exceeding a rent of £20. Presumably most of those persons were ratepayers assisting in bearing the burdens of the city until no longer able to do so. Had they been taken ill with one of the infectious fevers they would have been entitled to the use of the city hospital. But the municipality has as yet taken no steps to meet the case of consumption, although the disease from which they suffer is a more deadly one and one from the infection of which the public ought to be protected. It is no matter of philanthropy and no matter for the parish council to undertake. If the town authorities are to deal with those cases it must do so upon purely public and not on benevolent grounds. The town cannot set up for the exercise of benevolence, but it can justify on economic grounds the protection of the lives of the citizens from the great danger of a powerful infection. This is the principle upon which it carries on a hospital for the reception of persons afflicted with infectious diseases. It is true that there are municipalities where it is recognised to be a duty to take over the charge of citizens just entering upon consumption, where the expenditure upon effecting the cure of such persons is justified on economic grounds, upon the ground that those saved lives will prove as workers and wage-earners of far more value to the community than if they had been allowed to die. The committee do not venture to make any such proposal. They believe that if those dangerous cases which have got beyond the range of cure were provided for, the probabilities of a diminution of the disease in our city would be vastly increased; and that as the hopefulness of cure at the earlier stages of the disease comes to be realised and understood it will be found that the case will strongly appeal to wealthy and benevolent citizens. The committee recommends that when the new hospital for infectious diseases is opened at Colinton Mains 100 beds should be set apart in the present city hospital for the reception of advanced cases of consumption. The cost of this would be about £50 per annum per bed, or an annual expenditure of £5000. The committee believes that the resulting reduction in the mortality from consumption would more than repay the authorities for the expenditure involved. In an appendix there are brought together reports by Sir Henry D. Littlejohn, M.D., LL.D. Edin., medical officer of health, and of the conferences held by the special committee with leading physicians and surgeons, as well as recommendations from medical men.

*Aberdeen Working Men's Natural History Society.*

The annual meeting of the Aberdeen Working Men's Natural History and Scientific Society took place in Marischal College on Sept. 4th when the President delivered an address on the progress of the society, in which was urged the need for a proper museum for the city.

*The Plague Alarm in Aberdeen.*

In connexion with the outbreak of bubonic plague in Glasgow Professor M. Hay, M.D. Edin., medical officer of health of Aberdeen, has issued a short description of the symptoms of the plague for the guidance of the medical practitioners of the city. The medical officer of health and the sanitary inspector having both pointed out that Point Law, the centre of the herring fishing operations in Aberdeen, having no sanitary conveniences, is in an unsafe sanitary condition in the event of an outbreak of plague occurring, the Public Health Committee of the Town Council are to confer with a committee of the Harbour Commissioners on the subject of laying sewers for the efficient drainage of the district. Two suspicious cases have been observed—one at the City Hospital and one at the Royal Infirmary—but both have been authoritatively declared not to be cases of the plague. All the houses but one in Rennie's Wynd which are subject to flooding have been condemned as human habitations. These dwellings are sunk below the level of the present main outfall sewer which passes along the narrow wynd; there is a large factory within a few feet of the houses, and the action of the local authorities is not to be wondered at; but as usual they have taken no steps to provide cheap house accommodation elsewhere for the poor people to be displaced.

*Suggested Municipalisation of the Aberdeen Royal Infirmary.*

At a meeting of the "Citizens' One-Plank" Committee, held early in this month, a report on the proposed municipalisation of the Royal Infirmary was submitted by a sub-committee, in which it was contended that the system of voluntary support was wrong in principle since it allowed a large section of the citizens to evade their responsibilities towards the sick members of the community, while it also left the institution hampered for want of funds. A resolution was adopted to the effect that "this committee is of opinion that the only way of making adequate provision for the sick is by having the management of the infirmary placed in the hands of some popularly elected board with statutory rating powers at its disposal, and resolves to take whatever steps may be necessary to have that object realised." It was resolved to call a public meeting at an early date, and it may also be mentioned that, besides the Socialists, the United Trades Council have the same matter under consideration. The managers of the hospital are averse to any such radical change.

Sept. 11th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

*The late Sir William Stokes.*

HER Majesty the Queen has sent a message of gracious sympathy to Lady Stokes upon the death of her husband, the late Sir William Stokes, expressing her admiration of his noble, self-sacrificing works on behalf of her troops in South Africa and of the loss sustained by the distinguished profession to which he belonged in the death of one of its most eminent representatives. It will be remembered that the late Sir William Stokes was for some years Surgeon-in-Ordinary to the Queen in Ireland.

*Death of Dr. Arthur Wynne Foot.*

At a meeting of the standing committee of the Meath Hospital and County Dublin Infirmary held on Sept. 10th the following resolution, proposed by Mr. George Perry and seconded by Sir Philip Smyly, Surgeon-in-Ordinary to the Queen in Ireland, was passed unanimously:—

That the Standing Committee of the Meath Hospital having heard with deep regret of the decease of their late esteemed colleague, Dr. Arthur Wynne Foot, since their last meeting, desire to place on record their appreciation of his great services as physician, which for a period of over 21 years he rendered to this hospital, and to convey to Mrs. Foot the expression of their most sincere sympathy with her in her sore bereavement.

*The Royal Victoria Hospital, Belfast.*

At a meeting of the construction committee of this proposed new hospital held on Sept. 5th the eight tenders for the erection of the new hospital were opened, and after careful consideration the offer tendered by a Belfast firm, Messrs. M'Laughlin and Harvey, Limited, was unanimously accepted. The corporation of the city have arranged to give possession of the site for the hospital at once, and as by the contract the builders are bound to have it erected within two years and three months from the date of the execution of the contract no time will be lost. A small sub-committee was appointed to make arrangements for the laying of the foundation-stone, and it is hoped that this event will be honoured by H.R.H. the Prince of Wales. A committee was also appointed to look after matters of detail in connexion with the erection of the building and to advise the architect (Mr. Hennman of Birmingham) in regard to any points requiring adjustment which may present themselves during the progress of the work. The medical staff are represented on this committee. Subscriptions amounting to £81,162 5*s.* 5*d.* (together with interest) have been received and are lodged in the bank, while the promised subscriptions still outstanding amount to nearly £25,000. There is also a sum of £6653 14*s.* 10*d.* standing in the bank to the credit of the endowment fund, and this does not include sums received for the endowment of the "Cuming" ward, which will be handed over when the hospital is open. It is expected that the remainder of the subscriptions already promised will now be handed in.

*Death of Lieutenant-Colonel S. J. Flood, F.R.C.S. Edin., R.A.M.C.*

I regret to announce the death of Lieutenant-Colonel Flood, R.A.M.C., which took place at Holywood, Belfast, on Sept. 5th, the cause of death being pneumonia. Lieutenant-Colonel Flood was born at Danesfort, Belcoo, co. Fermanagh, in 1858, being the youngest son of the late Dr. Flood. He was a student at Queen's College, Galway, and at the

Ledwich School, Dublin. He was a Licentiate of the Royal College of Physicians and a Fellow of the Royal College of Surgeons of Edinburgh. In 1880 he joined the Royal Army Medical Corps, with which he saw service in Egypt and with which he was connected at the time of his death, being stationed at Holywood Barracks. He was very popular with his fellow officers and with the men. He leaves a widow and four children to mourn his premature decease.

*The British Association.*

The British Association at their meeting at Bradford accepted an invitation presented through an influential deputation on Sept. 7th to hold its meeting in 1902 in Belfast, a city which the members visited last in 1874, when Professor Tyndall was President, and the recollection of which has not yet passed into "the infinite azure of the past."

*The Outbreak of Typhoid Fever in Belfast.*

The recent report made public by the secretary of the Water Commissioners replying to the officials of the Public Health Committee, has caused a great sensation in Belfast and was very freely discussed at a special meeting of the city corporation on Sept. 7th. It is announced that the officials of the Public Health Committee will reply to it at the earliest possible moment. The thoughtful citizen, however, is getting pretty tired of this constant attempt made by two public bodies each to throw on the other responsibility for the prevalence of typhoid fever. One thing is clear, the water-supply of Belfast at present is not a first-class one, but to say that the water is the sole cause of the outbreak of typhoid fever is probably absurd, and even if it were the case would this in any way excuse the abominable sanitary defects which exist all over Belfast?

*Hospital Saturday in Belfast.*

Sept. 8th was Hospital Saturday, when a sum of over £500 was collected.

*Belfast Lunatic Asylum.*

It was decided at a meeting of the committee of the Belfast Asylum held on Sept. 10th to form a committee to confer with the medical superintendent with the view of making arrangements for the isolation of consumptive patients, of whom there are 13 suspected cases in the institution.

*An Inquisitive Workhouse Master.*

It would appear that the master of the Glenties Workhouse (co. Donegal) entered the dispensary of the Glenties district, which is situated in the front block of the workhouse buildings to get, according to his own statement, some boric acid for his eyes, and finding in his search two comparatively small parcels of post-mortem specimens, went next day, August 4th, to Belfast to consult the medical inspector of the Local Government Board for Ireland (Dr. C. J. Clibborn) in reference to the presence of the "two skeletons in the dispensary." On the inspector visiting the place, Mr. John Kelly, L.R.C.S. Irel., the dispensary medical officer showed him the parcels which were pathological specimens retained by him with the permission of private patients owing to their scientific interest. The matter was reported to the Local Government Board for Ireland and naturally in a district where superstition is rife it created a great deal of talk. The whole matter came up for consideration at the weekly meeting of the Glenties Board of Guardians on Sept. 10th, when after a long discussion the clerk was instructed to inform the Local Government Board that the board of guardians expressed their disapproval of the master's action in entering the dispensary and absenting himself without leave. They did not believe that he entered the dispensary for the purpose of getting boric acid and they unanimously expressed condemnation of his action. The whole matter is clearly a "mare's nest," and had the master simply mentioned the circumstance to the dispensary medical officer a simple explanation would have been given and disturbance and excitement in the district avoided.

Sept. 12th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

*The Soi-disant Claim of Pharmacists to Gratuitous Medical Attendance.*

A CURIOUS little case has just come before one of the *juges de paix*. It concerned a pharmacist who refused to discharge his medical attendant's bill. In justification of his action the pharmacist put forward the plea that medical men never charged pharmacists. It is true that as a matter of fact a medical man who is in personal relation with a pharmacist may receive from the latter particular services. In such a case the medical man makes a return by giving medical advice and treatment free. But this is merely a personal matter between two people in friendly relation and creates no right for any pharmacist to get medical advice free or for any medical man to get medicines at a less cost than the general public simply because he happens to be a medical man. In the case which has just been before the courts the medical man was dead and it was his heirs who claimed the amount of the bill, details of which had been regularly entered in the books. The pharmacist argued that he had custom on his side if he had not law, and that decisions in favour of the custom had already been pronounced by various *juges de paix* in similar cases. The pharmacist lost his case and the *juge de paix* who availed himself of the opinion of an expert founded his judgment upon the following considerations. "Seeing that the alleged custom does not exist as universal between pharmacists and medical men, but that if a medical man who has personal relations with a pharmacist does not charge the latter for medical attendance this is only in exchange for services rendered and is purely voluntary and a matter of courtesy, no rule is thereby laid down which can prevent a medical man from charging a pharmacist with whom he has no habitual relations and who has not rendered him any services." It was admitted by D—— that Dr. B—— was not his usual medical attendant.

*The Adoption of an International Nomenclature for Causes of Death.*

Scarcely one month ago Dr. de Maurans drew attention to the difficulties which the diversities of medical terminology threw in the way of international scientific coöperation and he urged that it was the duty of the International Congresses to lay down some basis for a nomenclature which should be common to all countries. This appeal has been heard. The official delegates to the International Congress of Hygiene and Demography held in Paris from August 10th to 17th have decided that in order to make the work of comparison between the nosological statistics of different countries possible a uniform nomenclature should be adopted. The committee gave as an example the statistics adopted by the city of Paris, and all the delegates save one have agreed to recommend to their respective countries that the new nomenclature should come into force on Jan. 1st, 1901—that is to say, at the commencement of the twentieth century. It has already been agreed that French nomenclature shall be the one to be used in North and South America and in a great number of European countries.

*The Application to Man of the Regeneration of Confined Air by the Use of Peroxide of Sodium.*

M. A. Desgrez and M. V. Balthazard have laid before the Academy of Medicine[1] a method of regenerating confined air by the decomposition of peroxide of sodium by the use of cold water. They showed that the oxygen given off by the decomposition replaced that used in respiration, and simultaneously that the soda formed took up the carbon dioxide formed by the respiration, and finally that the toxins present in expired air were destroyed by the oxidising agent. Animals confined in a small space, but where the air was regenerated by this process, survived, while control animals in whose case no regeneration was practised died. Since then they have applied the process in the case of men and have made known their results. Their early experiments were made with a somewhat cumbrous apparatus and they were obliged to simplify it. A model which they showed can, however, be carried on the back and weighs about 12 kilogrammes.

## SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

*Bâle Sanatorium for Phthisical Patients.*

DR. F. EGGER reports on this sanatorium which is situated at Davos and which with its 86 beds suffices for the necessities of the canton of Bâle, as 300 patients can be received annually, the average length of stay being 108

[1] THE LANCET, Feb. 25th, 1899, p. 552.

days. He separates the 530 patients—mostly of the working-classes and indigent population—who were received during the three years 1897 to 1899 into three classes. 1. (*a*) Initial cases with apex infiltration only; and (*b*) more chronic cases with localised lesions. 2. Recent and chronic cases with lesions of not more than one lung, but in good general condition. 3. More advanced cases with fever and such of a progressive character or with other tuberculous complications. Of the 284 cases in Class 1 111 were discharged cured, 120 were considerably improved, 38 were improved, 10 were stationary, and five were aggravated. Of 144 cases in Class 2 one was cured, 68 were greatly improved, 60 were improved, nine were stationary, five were worse, and one had died. Of 102 cases in Class 3 21 were greatly improved, 44 were improved, 16 were stationary, 16 were worse, and five had succumbed to the disease. Dr. Egger next discusses after results, which are of greater importance, especially to the patient. This refers only to patients one to three years after dismissal. 58 cases in Class 1 (*a*), 71 cases in Class 1 (*b*), 37 cases in Class 2, and five cases in Class 3, or a total of 171 cases out of 272 that could be traced were fit for work and would probably continue so; 16 were working (after result doubtful), 12 were only partially occupied, 19 were not fit for work, and 54 had died. (27 could not be traced.) Dr. Egger earnestly pleads for patients being sent to Davos in the initial stage, and his statistics support him. He objects to the diagnostic use of tuberculin on the strength of Dr. Knopf's (New York) statement that a latent tuberculosis can be stirred up from its quiescent state and terminate fatally. Out of 148 patients who were weighed from one to three years after their discharge and after resuming their usual occupations, 42·6 per cent. had increased in weight since leaving the sanatorium, 32·4 per cent. weighed more than before admission, 10·8 per cent. weighed the same, and only 14·2 per cent. had decreased in weight. However, a convalescent home near Bâle for some of the discharged patients is very desirable and the idea will soon be realised.

Zürich, Sept. 10th.

## ROME.

(FROM OUR OWN CORRESPONDENT.)

*Consular Report for 1899.*

IN his report recently issued the British Consul at Rome gives the following figures to show the diminution which has been effected in the death-rate of the city during the last quarter of a century:—

| Year. | Mortality per 1000 inhabitants. |
|---|---|
| 1875 ... ... ... ... ... ... ... | 33·9 |
| 1887 ... ... ... ... ... ... ... | 22 8 |
| 1899 ... ... ... ... ... ... ... | 17·2 |

The death-rate for 1899 compares very favourably with that of other towns in Italy and on the continent, as may be seen by another table from the same report:—

| 1899. | Death-rate per 1000 inhabitants. | 1899. | Death-rate per 1000 inhabitants. |
|---|---|---|---|
| Rome ... ... ... | 17·2 | Budapest ... ... | 22·3 |
| Leghorn ... ... | 19·0 | Cologne ... ... | 23·1 |
| Venice ... ... ... | 22·2 | Munich... ... ... | 23·9 |
| Bologna ... ... | 24·1 | St. Petersburg ... | 24·7 |
| Paris ... ... ... | 20·1 | Madrid ... ... ... | 30·1 |

There were five births, 22 deaths, and five marriages of British subjects during the year.

*Progress of the Anti-malarial Campaign.*

The Red Cross Society reports that during the first period (July 1st to July 23rd) of the experiments now being carried out under its auspices in the Agro Romano 30 patients were conveyed to Rome or elsewhere by the seven ambulances engaged in the work. During the second period (July 24th to August 15th) 61 patients were so transported. The medical officers attached to the ambulances attended during the first period to 880 patients, of whom 528 were affected with malaria, and during the second period to 892 patients, of whom 801 were malarial. In spite of the notoriously unhealthy character of the localities in which the ambulances are stationed no single member of the staff, either among medical men or attendants, had contracted fever during these two periods. The immunity thus enjoyed by the members of the mission is ascribed to the precautions adopted by the municipality for preventing the entrance of mosquitoes to the rooms in which the men sleep and is to be regarded as a further confirmation of the correctness of the mosquito theory of malarial infection.

*The Sanatoria for Tuberculosis.*

A Government Commission has been appointed to examine the scheme for the establishment of the proposed "Sanatorio Umberto I. per la Tubercolosi" described in my last letter. It has for its president Professor Bizzozero of Turin, and includes amongst its nine members Professor Durante and Professor Ballori of Rome, Professor De Giovanni of Padua, and five engineers from Milan, Turin, Rome, Naples, and Pisa respectively. The Parliamentary Committee charged with the duty of submitting the project to the Government is a large one, consisting of 29 deputies, and is presided over by Professor Baccelli. At Leghorn the municipality have taken in hand the foundation of the sanatorium for that city; the local savings bank has contributed a sum of 45,000 lire (£1800), and several members of the promoting committee offer handsome subscriptions towards it. At Pisa the communal council have passed a resolution devoting a sum of 30 000 lire (£1200) to a like object and soliciting in its favour the support of the province and communes.

Sept. 11th.

# Obituary.

WILLIAM MARSHALL, M.D. ST. AND., L.F.P.S. GLASG.,
CONSULTING PHYSICIAN TO THE DUMFRIES AND GALLOWAY ROYAL INFIRMARY.

THE death is announced, on August 30th, of Dr. William Marshall of Dumfries at the age of nearly 80 years. Born in Caledon, county Tyrone, where his father, Mr. Huggins Marshall, was then resident, William Marshall received his medical education in Glasgow, taking the L.F.P.S. in 1845 and the M.D. at St. Andrews University in the same year, after which he went to the Southern States of America. Returning home in 1848 he was sent with 11 others to Dumfries to assist during the cholera epidemic of that year. On the cessation of the outbreak Dr. Marshall remained in the town as assistant to the late Dr. McCulloch and after a few years started practice on his own account. He was recognised as a skilful practitioner and his kind and genial manner secured for him a host of friends and an extensive connexion. Dr. Marshall took a keen interest in the affairs of Dumfries, served on its town council, and supported zealously schemes for improving the sanitary condition of the town, notably in regard to its water-supply. He was specially concerned in the welfare of the Dumfries and Galloway Royal Infirmary, on the medical staff of which he served up to about four years ago, when he retired and was appointed consulting physician. He was also medical officer to the Dumfries Parochial Board for over 40 years, being eventually assisted by his elder son who, unfortunately, predeceased him. Dr. Marshall was one of the first in the district to be connected with the Volunteer movement and served as surgeon for some eight years, taking part in the review by the Queen in 1860. He possessed all the wit and charm of manner which distinguish the natives of the Emerald Isle. He was a capital *raconteur*, and not even severe suffering would prevent him from making witty remarks and telling a good story. He took a close interest in all outdoor sports, especially coursing, bowling, and curling. He was fond of music and until a contraction of his little finger became pronounced he was no mean performer on the violin. He was an ardent Freemason and recently was an office-bearer in the provincial lodge. Dr. Marshall was twice married and has one surviving son now in New Zealand.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Gervais-Koyziewicz, Surgeon of the Bordeaux Hospitals.—Dr. Domingos Freire of Rio de Janeiro, whose work in the direction of searching for the cause of yellow fever and his attempts to render individuals immune to it are well known.—Dr. F. H. Frölich, Surgeon-General in the Saxon Army and a well-known author, at the age of 63 years.

# PRIZES AND SCHOLARSHIPS AT THE MEDICAL SCHOOLS.

THE following is a list of prizes, &c., awarded for the sessions of 1899–1900:—

*St. Bartholomew's Hospital.*—Lawrence Scholarship and Gold Medal: C. J. Thomas. Brackenbury Medical Scholarship: A. T. Pridham. Brackenbury Surgical Scholarship: C. E. West. Matthews Duncan Medal and Prize: R. H. Paramore (Prize). Senior Scholarship in Anatomy, Physiology, and Chemistry: N. E. Waterfield. Entrance Scholarships—Chemistry and Physics: not awarded; Biology and Physiology: not awarded; (Junior) H. D. Clementi-Smith and K. S. Wise, equal; Preliminary Scientific Exhibition: not awarded; Jeaffreson Exhibition: M. B. Reichwald; Shuter Scholarship: H. H. Dale; Kirkes Scholarship and Gold Medal: A. E. H. Thomas. Bentley Prize: E. E. Young. Hichens Prize: A. Hamilton. Wix Prize: N. E. Waterfield. Harvey Prize: A. Hamilton. Sir George Burrows Prize: C. E. West. Skynner Prize: F. C. Shrubsall. Practical Anatomy (Junior)—Treasurer's Prize: W. Hamilton; (2) E. F. Travers, (3) T. J. Faulder, (4) C. E. Denton, (5) S. M. Lawrence, (6) W. C. Pickering, (7) C. H. Fielding, (8) H. Beckton, (9) W. H. Barnett. Practical Anatomy (Senior)—Foster Prize: (1) W. A. Aldred and H. V. Wenham, equal; (2) T. H. Harker, (3) J. Burfield, (4) A. C. Brown and C. C. Robinson, equal; (5) A. Hamilton, (6) A. F. Forster, (7) G. B. Aubrey. Junior Scholarships in Anatomy and Biology (1900): (1) T. J. Faulder, (2) E. E. Maples. Junior Scholarships in Chemistry and Histology (1899): (1) C. C. Robinson, (2) W. A. Aldred.

*Charing Cross Hospital.*—Livingstone Scholar: P. Rees. Huxley Scholar: R. R. Huxtable. University Scholars: A. E. Taylor and H. F. Skrimshire. Epsom Scholar: C. H. F. Johnston. Llewellyn Prize (£25): H. S. Gabb. Governors' Clinical Gold Medal: C. H. Fennell. Golding Prize: Certificate and £10, P. Gully. Pereira Prize: Certificate and £5, A. G. Pitts. Anatomy (Senior): Prize, A. G. Payne; Certificate, F. J. Pierce. Anatomy (Junior): Prize, C. G. Riddett; Certificates, P. Rees, H. Smith, P. Gully, A. G. Finch, and H. B. Sawday (equal), L. P. Maitland, and C. H. F. Johnston. Biology: Prize, P. Gully; Certificates, H. H. R. Bayley, H. F. Strictland, and G. C. Pounds. Chemistry: Prize, P. Gully; Certificates, C. P. Tessier, C. L. Saies, A. G. Finch, H. H. R. Bayley, and G. C. Pounds. Physiology (Senior): Prize, G. C. M. Davies. Physiology (Junior): Prize, G. Sheppard; Certificates, L. P. Maitland, P. Rees, H. Smith, and A. G. Finch. Medicine (Senior): Prize, H. S. Gabb: Certificates, J. P. Candler, G. O. Lambert, and E. F. Ackery. Medicine (Junior): Prize, A. E. Taylor; Certificate, H. M. Skrimshire. Surgery (Senior): Prize, Mr. E. F. Ackery. Surgery (Junior): Prize, H. F. Skrimshire. Practical Medicine: Prize, A. G. Pitts and G. O. Lambert (equal); Certificates, C. J. A. Mercier and A. R. F. Hubbard. Practical Chemistry: Prize, S. G. Amoore; Certificates, V. N. Whitamore, J. L. O. Tilley, A. G. Finch, and G. F. Denning. Psychological Medicine: Prize, H. S. Gabb; Certificates, A. G. Pitts, J. D. Rolleston, G. O. Lambert, and E. F. Ackery. Practical Midwifery: Prize, B. R. Lloyd; Certificates, A. G. Pitts and A. E. Taylor (equal). Midwifery: Prize, H. S. Gabb; Certificate, A. C. Ingram. Pathology: Prize, G. O. Lambert; Certificates, B. G. Fiddian and H. S. Gabb (equal); B. R. Lloyd and C. J. A. Mercier (equal). Public Health: Prize, C. H. Fennell; Certificate, D. V. Muller. Therapeutics: Prize, J. D. Rolleston. Forensic Medicine and Toxicology: Prize, B. G. Fiddian. Materia Medica: Prize, C. L. Lakin; Certificate, R. H. Cooper.

*Guy's Hospital.*—Open Scholarships in Arts: Frank Thomas Herbert Wood, Roan School, Greenwich, £100; Herbert Stanley Knight, Bancroft's School, Woodford Wells, £50; and Herbert Andrew Watney, Trent College, Derbyshire, Certificate. Dental Students: Osborne Black, Foyle College, Londonderry, £30. Open Scholarships in Science: Henry Francis Bell Walker, Stockport Grammar School, and private study, £150; John Hunter Clatworthy, Guy's Hospital, £60; Gerald Russell, Guy's Hospital, Certificate; and Harry Hunter Carter, Guy's Hospital, Certificate. Scholarship for University Students: Paul Norman Blake Odgers, Lincoln College, Oxford, £50; Greer Edmund Malcomson, Owens College, Manchester, Certificate; and Frederick Henry Parker, Pembroke College, Cambridge, Certificate. Junior Proficiency Prizes: Percy Reginald Bolus, £20; Edwin Henry Britton Milsom, £12 10*s.*, and Neville Ivens Spriggs, £12 10*s.* (equal); Kenneth Black, Certificate; Reginald Larkin, Certificate; and Alexander Moxon Webber, Certificate. Michael Harris Prize for Anatomy: Alexander Moxon Webber, £10; Reginald Larkin, Certificate; and William Leigh Maule Day and Lionel Henry Moiser (equal Certificates). Wooldridge Memorial Prize for Physiology: Percy Reginald Bolus, £10; Neville Ivens Spriggs, Certificate: and Edwin Henry Britton Milsom, Certificate. Hilton Prize for Dissection (1899): Harold Tipping, £2 10*s.*, and Alfred Herbert Edwin Wall, £2 10*s.* (equal). Arthur Durham Prizes for Dissection—First Year's Students: Edward Crosby Peers, £5. Senior Students: Alexander Moxon Webber, £15; Geoffrey Carlisle, Certificate; and Frederick Rogerson, Certificate. Dental Prizes—First Year's Students: Gerald Hamilton Morris, £10; and Samuel William Iles, Certificate. Second Year's Students (1899): John Black, £15; and Francis Wilberforce Garman and Harold Maurice, equal Certificates. Practical Dentistry Prize: Gerald Hamilton Morris, £5, and Arthur Henry Clogg, £5 (equal). Senior Proficiency Prizes: Graham Scales Simpson, £20; and Edward Cohen (Certificate). Treasurer's Gold Medal for Clinical Surgery: Graham Scales Simpson. Beaney Prize in Pathology (1899): Caleb Thomas Hilton, £34; and Frank Shufflebotham (Certificate). Richard Bredin Prize for Clinical Study: Caleb Thomas Hilton, £25.

*King's College, London.*—Sambrooke Exhibitions: Eardley Lancelot Holland, Thomas Henry Jones, and John James. Medical Entrance Scholarship: Arthur James Wigmore. Warneford Scholarships: John Alexander Drake and Matthew Robert Cecil McWatters. Senior Scholarship: Arthur Edmunds. Second Year Scholarship: Harold Benjamin Day. Junior Scholarships: Thomas Henry Jones and Eardley Lancelot Holland. Rabbeth Scholarship: Frederick Champ McCombie. Leathes Prize: Harold Balme and Colin James Galbraith. Warneford First Prize: Harold Balme; Second Prize: Edward Augustine Bell. Barry Prize (Divinity): Arthur Donald Griffith. Tanner Prize: Edgar Winn Fox Dolman. Todd Prize: Arthur Edmunds. Hygiene Prize: James Duncan Clay. Pathological Anatomy Prize: Alfred Hocart Brehaut. Obstetric Medicine, Forensic Medicine, and Medicine Prizes: Archibald Douglas Reid. Surgery Prize: Frederick Charles Carle. Professor Rose's Surgery Prize: Hubert Liston Willcox. Anatomy, Physiology, Chemistry, and Materia Medica Prizes: Albert Angelo Myers.

*London Hospital.*—Price Scholarship in Science (£120): R. Milne. Price Scholarship in Anatomy and Physiology (£60): A. W. S. Fisher. Entrance Science Scholarships—£60 Scholarship: T. D. Smith; £35 Scholarship: G. A. Soltau (equal, scholarship divided). Buxton Scholarships in Arts—£30 Scholarship: J. A. Mulvany; £20 Scholarship: J. E. Hoar. Epsom Scholarship for Students of Epsom College: L. Warren. Clinical Medicine—£20 Scholarship: A. B. Soltau and J. H. Philbrick (equal, Scholarship divided); Honorary Certificate: H. P. Bradley. Clinical Surgery—£20 Scholarship: A. B. Soltau; Honorary Certificates: A. L. Matthews, G. F. Barham, and W. Steen. Clinical Obstetrics—£20 Scholarship: W. F. Ellis; Honorary Certificates: A. L. Matthews, F. Challans, I. Stusser, and H. Balean. Duckworth Nelson Prize (Biennial, £10): awarded in 1899. Andrew Clark Prize—(Biennial, £26): H. P. Bradley; Honorary Certificate: A. B. Soltau. Letheby Prizes—Senior (£20): M. Culpin; Honorary Certificate: J. A. Milne; Junior (£10) T. D. Smith. Honorary Certificates: R. Milne, A. G. Tresidder, and V. E. Ridewood. Hutchinson Prize—(Triennial, £35): next award in 1902. Anatomy and Physiology—£25 Scholarship: M. T. Williams. Honorary Certificates: H. B. W. Smith, H. R. Cran, and R. V. Dolbey. Anatomy and Biology—£20 Scholarship: R. Milne; Honorary Certificate: D. T. Smith. Minor Surgery Prizes—£15 Prize: C. D. Walsh; £10 Prizes: J. Avery and H. B. W. Smith; £5 Prizes: A. C. Dixon, N. W. Hill, H. W. B. Danaher, R. V. Dolbey, and N. C. Wallis. Honorary Certificates: F. H. Rotheram and F. Todd. Practical Anatomy—£6 Prize: R. L. Ridge; £4 Prize: E. S. Molyneux; Honorary Certificates: F. W. Jones, H. H. Bashford, and T. S. Dudding. Anderson Prizes—£2: A. Simey, C. E. Ham, and R. A. Eastmonde. £1: A. J. Couzens, A. W. S. Fisher, and W. B. Vaile. Honorary Certificates: C. V. Bulstrode, R. Burges, E. M. Clarke, L. C. Coode, H. P. Croby, E. F. Fisher, H. R. Jeremy, H. E. Ridewood, A. M. Simpson, J. E. Spicer, I. Stusser, and E. Weatherhead.

*Middlesex Hospital*.—Entrance Scholarships: (1) W. N. Kingsbury and (2) T. R. Felix. University Scholarship: L. Courtauld. Broderip Scholarship: (1) F. D. Blandy, and (2) W. P. Panckridge. The Governors' Prize: F. D. Blandy. Hetley Prize: F. D. Blandy. Lyell Medal: R. F. C. Ward. Leopold Hudson Prize: T. W. Scott. Second Year's Exhibition: P. G. Foulkes; W. Gillitt (*proximé accessit*). First Year's Exhibition: W. G. Taylor. Medicine and Surgery Prizes: J. S. Goodall. Surgery Certificate: N. Black. Practical Medicine Prize: E. R. Griffiths. Certificates: C. E. Lakin, H. R. Dutton, and T. W. Scott (equal), G. P. Duprey, and G. H. K. Young. Practical Surgery Prize: L. F. Lovell-Keays; Certificates: G. P. Duprey, D. Smith, E. R. Griffiths, S. Hastings, R. Phillips, and C. W. Rowntree. Forensic Medicine and Public Health Prize: R. A. Pitter; Certificate: C. E. Lakin. Mental Diseases Prize: C. E. Lakin. Pathology Prize: A. E. Pinniger; Certificate: S. Hastings. Midwifery Prize: D. J. Thomas; Certificate: H. B. Smith. Practical Midwifery Prize: G. E. Froggatt; Certificates: T. W. Scott, D. T. Jones, C. E. Blackstone, and F. B. Penfold. Pharmacology and Therapeutics Prize: D. J. Thomas; Certificates: T. Rose and J. W. Hele. Anatomy Prize: W. Gillitt; Certificates: F. G. Foulkes, I. D. Jones, and T. Rose. Dissections Prize: W. Gillitt; Certificates: J. W. Hele and I. D. Jones. Physiology Prize: F. C. Foulkes; Certificate: W. Gillitt. Histology Prize: W. C. Macaulay; Certificates: H. W. Perkins and W. C. Taylor. Chemistry Prize (winter session): C. H. B. Thompson; summer session: F. L. Dickson; Certificate: J. C. L. Hingston. Practical Pharmacy Prize: T. R. Felix; Certificates: F. L. Dickson and W. C. Macaulay.

*St. Mary's Hospital*.—Entrance Scholarships—in Natural Science of £144: J. N. Kilner; £78 15*s*.: C. J. Singer; £78 15*s*. (not awarded). Exhibition in Natural Science of £26 5*s*: U. Marks. University Scholarships of £57 15*s*.: A. H. Thomas and Gnoh Lean Tuck, B.A. Exhibitions of £26 5*s*.: B. H. Spilsbury, B.A., A. G. Bate, B.A., and H. M. Wilson, B.A. General Proficiency Scholarships of £20 each—for Proficiency in Anatomy, Physiology (including Histology), Biology, Chemistry, and Physics (not awarded); for Proficiency in Anatomy and Physiology (including Histology): M. F. Kelly; for Proficiency in Midwifery, Pathology, Medical Jurisprudence, and Materia Medica: H. J. Van-Praagh; for Proficiency in Medicine and Surgery (including Operative Surgery): W. H. Willcox, B.Sc. Special Prizes—Gold Medal in Clinical Medicine: W. H. Willcox, B.Sc.; Kerslake Scholarship in Pathology and Bacteriology: W. V. Shaw, B.A.; Meadows Memorial Prize in Obstetrics: H. J. Van-Praagh; Clinical Medicine: H. J. Van-Praagh and B. F. Hussey; Clinical Surgery: W. V. Shaw, B.A., and J. F. E. Bridger (equal); Ophthalmology: R. R. Cruise and R. Hobbs; Dermatology: W. Sass and H. T. Doble; Prosectors: W. L. M. Goldie and J. H. Burgess. Class Examinations, Summer Session, 1899—Hygiene Prize: B. F. Hussey; Certificate: J. Klein; Materia Medica Prize: W. J. Morrish; Obstetrics Prize: E. W. Holyoak; Certificate: A. Whitmore, B.A.; Medical Jurisprudence Prize: B. F. Hussey; Certificate: E. L. Jenkins; Psychological Medicine Prize: W. H. Willcox, B.Sc.; Practical Chemistry Prize: E. G. R. Lithgow; Certificate, H. E. Batten; Chemistry Prize: U. Marks; Certificate, G. E. Peachell. Winter Session, 1899–1900—Medicine Prize, not awarded; Certificates: J. Tattersall, E. R. Clarke, B.A., and J. C. Matthews, B.A.; Surgery Prize: W. H. Clayton-Greene, B.A.; Certificates: C. H. Brodribb and R. R. Cruise: Practical Surgery Prize: C. H. Brodribb; Certificates: W. H. Clayton-Greene, B.A., J. F. E. Bridger, and T. H. J. E. Hughes; Pathology Prize: J. C. Matthews, B.A.; Certificates: F. M. G. Tulloch and E. R. Clarke, B.A.; Physiology (Senior) Prize, not awarded; Certificate: E. L. Ash; Physiology (Junior) Prize: W. K. D. Breton; Certificates: G. E. Peachell and A. F. Cole; Histology Prize: J. H. Burgess; Certificate: E. L. Ash; Anatomy (Senior) Prize: W. L. M. Goldie; Certificates: A. C. Motta and J. H. Burgess; Anatomy (Junior) Prize: G. E. Peachell; Certificate: J. N. Kilner; Biology Prize: S. H. Kilroe; Certificates: E. C. Young and F. C. Lloyd.

*St. Thomas's Hospital*.—Winter Session, 1899–1900.—Entrance Science Scholarships—First Scholarship (£150) and Certificate of Honour: L. Bathurst; Scholarship (£60) and Certificate of Honour: L. Craske. University Scholarship—Scholarship (£50) and Certificate of Honour: A. C. Hudson. First Year's Students—William Tite Scholarship (£27 10*s*.) and Certificate of Honour: K. Takaki. Second Year's Students—Peacock Scholarship (£38 10*s*.) and Certificate of Honour: H. S. Bennett; Certificate: F. W. W. Smith. Third Year's Students—Musgrove Scholarship (second tenure) and Certificate of Honour: S.U. Ind. Fifth Year's Students—College Prize (£10): F. C. Eve (Medicine); College Prize (£10): W. H. O. Woods (Surgery); College Prize (£10): T. S. Taylor (Midwifery); Hadden Prize (£10): J. E. H. Sawyer (Pathology); College Prize (£10): J. L. Lock (Pharmacology); College Prize (£10): R. B. Kinloch (Forensic Medicine and Insanity); and College Prize (£10): W. B. Fry (Public Health). Practical Medicine—Mead Medal: R. B. Kinloch; Certificate of Honour: F. C. Eve. Surgery and Surgical Anatomy—Cheselden Medal: T. H. Edwards. Pathology and Morbid Anatomy—Bristowe Medal: C. L. Hawkins; Certificates of Honour: A. E. Martin and L. S. Dudgeon. Grainger Testimonial Prize (£15): F. C. Eve. For Reports of Surgical Cases—Solly Medal and Prize: J. E. H. Sawyer. For General Proficiency and Good Conduct—Treasurer's Gold Medal: F. B. Skerrett.

*University College, London*.—Entrance Scholarships: Bucknill Scholarship (£120): G. Hall. Intermediate Medical Course (£57 15*s*. each): J. A. Ferrière and E. Mapother. Final M.B. Course (£79 16*s*. each): C. S. Parker and T. L. Llewellyn. Atchison Scholarship (£55 per annum for two years): R. E. Lloyd. Bruce Medal: R. E. Lloyd. Physiology (Professor E. H. Starling, M.D., F.R.C.P., F.R.S.)—Senior Class: Gold Medal, A. M. H. Gray. Third Class: G. S. Hett. Junior Class: Silver Medal, R. A. Greeves. Certificates: (2* equal) J. A. Ferrière and G. Hall, (4*) R. S. Woods, and (5*) E. G. Perodeau. Second Class: A. G. C. Findlay. Third Class: N. S. Finzi, P. M. Roberts, C. S. White. Anatomy (Professor G. D. Thane, Sub-Dean)—Senior Class—1st Silver Medal: A. M. H. Gray; 2nd Silver Medal: G. S. Hett. Third Class: C. H. Berry and M. W. Stewart-Smith. Junior Class—Silver Medal: R. A. Greeves. Certificates: (2*) G. Hall and (3*) C. D. Holdsworth. Second Class: J. A. Ferrière, G. E. O. Williams, R. S. Woods. Third Class: W. Appleyard, A. J. Blaxland, H. Farncombe, and A. G. C. Findlay. Medicine, Professor F. T. Roberts, M.D., B.Sc.—Second Class: L. G. Hopkins, A. E. Jones, and R. E. Lloyd. Surgery (Professor A. E. Barker, F.R.C.S.)—Gold Medal: R. E. Lloyd; Silver Medal: L. G. Hopkins. Second Class: A. E. Jones. Pathology (Professor Sidney Martin, M.D., F.R.S.)—Morbid Histology and Bacteriology—Tuke Silver Medal: T. L. Llewellyn. Third Class: C. S. Parker. Practical Surgery (Bilton Pollard, B.S., F.R.C.S., and Raymond Johnson, B.S., F.R.C.S.)—Erichsen Prize: L. G. Hopkins. Certificates: (2*) S. H. Bown, (3*) O. L. Addison, and (4*) T. C. Savage. Second Class: S. Bree, R. E. Lloyd, H. W. Reynolds, and A. N. Stevens. Clinical Medicine (Professor Sydney Ringer, M.D., F.R.S.)—Senior Class: Fellowes Gold Medal: H. W. Reynolds; Fellowes Silver Medal, A. E. Jones; Certificate: (3*) T. C. Savage. Second Class: D. L. Davies, A. Emerson, L. G. Hopkins, R. E. Lloyd, and G. A. Upcott-Gill. Junior Class (Professor J. Rose Bradford, M.D., D.Sc., F.R.S.)—Fellowes Silver Medal: A. F. Horn; Certificates: (2*) G. E. Waugh, (3*) C. S. Parker, and (4*) J. E. Stratton. Second Class: J. B. Burt, W. T. Crawford, L. A. E. de Zilwa, T. L. Llewellyn, and W. Parsons. Third Class: J. C. Fleming and F. J. Lawson. Clinical Dental Surgery (Lecturer, P. S. Spokes, M.R.C.S.)—Silver Medal, L. G. Hopkins. Certificates (2* equal) A. E. Jones and R. E. Lloyd. Honours List, 1899–1900.—Entrance Scholarships: E. H. Bennett-Bailey (110 guineas), C. G. Browne (£50), H. C. Hocken (£40), L. White (£40), P. Farrant (£40), H. G. L. Haynes (£40), C. D. Fox (£40), and W. H. France (£30). "Chadwick" Prize (value 20 guineas): W. Payne (Prize) and F. W. W. Dawson (Certificate). "Bird" Prize and Medal (value £14): W. Payne. Medicine: F. W. W. Dawson (Prize). Surgery: W. Payne (Prize) and F. W. W. Dawson (Certificate. Clinical Surgery: W. Payne.

* Obtained the number of marks qualifying for a Prize.

*University College, Bristol*.—Medicine Prize: P. G. Stock; Certificate: S. J. Willcox. Surgery Prize: R. G. Johnson; Certificate: P. G. Stock. Public Health Prize: T. Aubrey; Certificates: J. R. Frost and A. G. G. Plumley (equal). Senior Anatomy Prizes: J. D. C. Calcott and J. E. Sparks (equal). Junior Anatomy Prize: A. R. Short. Physiology Prizes: J. D. C. Calcott and J. E. Sparks (equal). Practical Physiology and Histology Prize: J. E. Sparks; Certificate: F. Parlett. Biology Prize: G. B. Gill; Certificate: W. T. Webb. Chemistry Certificates: G. B. Gill and

H. E. Hopper. Midwifery Prize: R. G. Johnson. Medical Jurisprudence Certificate: T. Aubrey. Pathology and Morbid Anatomy Prize: T. Aubrey. Operative Surgery Certificate: T. Aubrey. Practical Medicine, Surgery, and Midwifery Certificate: R. G. Johnson. Materia Medica and Practical Pharmacy Prize: H. de Vine; Certificate, A. R. Short. Practical Chemistry Prize: G. B. Gill. *Bristol Royal Infirmary*—Second Entrance Scholarship (value 10 guineas): H. O. Gough and P. Moxey (equal). Clarke Prize (interest of £489), for third year's students: P. G. Stock. Suple Medical Prize (gold medal and seven guineas in money), for students of the fifth year: James Phillips. Suple Surgical Prize (gold medal and seven guineas in money), for students of the fourth year: J. R. Frost. Tibbits Memorial Prize (value nine guineas), for Proficiency in Practical Surgery: J. R. Frost and E. M. Pearse (equal). Pathological Prizes (value three guineas): J. R. Frost and James Phillips. Ophthalmic Prize (value three guineas): P. G. Stock. Special Certificates in Obstetric Medicine: F. A. Coates, J. R. Frost, H. Hemsted, W. B. Prowse, and P. G. Stock. Dental Prize (value three guineas): S. J. Willcox. Special Dental Prize: J. L. O. Tilley. *Bristol General Hospital.*—Lady Haberfield Entrance Scholarship (interest of £1000): H. de Vine. Sanders Scholarship (value £22 10*s.*), for Proficiency in Medicine, Surgery, and Obstetric Medicine: R. G. Johnson. Clarke Scholarship (value £15), for Proficiency in Surgery: R. G. Johnson.

*Queen Margaret College.*—Winter Session—Medal in Chemistry: Christian E. S. Smart. Medal in Anatomy: Gertrude D. Bostock, B.Sc. Medal in Physiology: Isabel D. Mitchell. Medal in Materia Medica: Gertrude D. Bostock. Medal in Pathology: Margaret E. Bryson. Medal in Surgery: Mary J. Pirret. Medal in Practice of Medicine: Elizabeth M. Sloan. Medal in Midwifery and Gynæcology: Elizabeth M. Sloan. Summer Session—Medals in Practical Physiology and Practical Pharmacy: Eliza J. Miller. Medal in Practical Pathology: Martha H. Scott. Medal in Medical Jurisprudence and Public Health: Gertrude D. Bostock. Prize in Ophthalmology: Martha H. Scott.

*Anderson's College Medical School.*—Winter Session, 1899-1900. Junior Anatomy—Kerr Bursar: David L. Provan, Wishaw. Certificates of Honour (in order of merit): David L. Provan, Wishaw; Reginald N. Macdonald, Buenos Ayres; Charles H. Osmond, Somerset; William Cameron Bower, Bradford; Percy J. Thomson, Glasgow; and John Miller, Glasgow. Senior Anatomy—Certificates of Honour (in order of merit): William Don, Glasgow; William Pritchard Airey, Liverpool; John M. Kelly, Kilmarnock; and Robert Wallace, Glasgow. Anatomy Prosectors: Reginald N. Macdonald, Buenos Ayres; and Charles H. Osmond, Somerset. Summer Session, 1900—Senior Anatomy—Certificates of Honour (in order of merit): John F. Webster, Paisley; Reginald N. Macdonald, Buenos Ayres; and James Eadie, Glasgow. Physiology (Professor W. Ernest Thomson, M.A., M.D.). Winter Session, 1899-1900—Medal and First-class Certificate of Honour: John F. Webster, Paisley. Special Prize and Certificate for Practical Work: Reginald N. Macdonald, Buenos Ayres. Practical Physiology—Summer Session, 1900—Medallist: Ian Campbell, Crieff. Certificates of Honour—First Class: Ian Campbell, Crieff, and C. H. Osmond, Somerset; Second Class: L. E. Jarrett, Kent. Materia Medica and Therapeutics (Professor R. Barclay Ness, M.A., M.B.)—Winter Session, 1899-1900—Medal: Henry Doig, Glasgow. Certificates of Honour (in order of merit)—First Class: Henry Doig, Glasgow; David Moodie, Galashiels; and Robert Roberts, Anglesea; Second Class: James H. Milne, Glasgow. Dental—Second Class (in alphabetical order): John Christie, Glasgow, and William Patterson, Glasgow. Practice of Medicine (Professor Samson Gemmell, M.D.).—Winter Session 1899-1900—Senior Division—First Prize: A. D. Thompson, Forfar, and Alexander Wilson, Glasgow (equal); Second Prize: George White, Glasgow. First Class Certificates (in order of merit): James Millar, Kilwinning; Hugh P. Wright, Glasgow; Edward P. Cathcart, Ayr; John Forrest, Glasgow; Jacob Mains, Liverpool; Charles E. Cuthbert, Glasgow; Thomas T. Bathgate, Bellshill; W. B. J. Pollock, Glasgow; and James Scott, Glasgow. Junior Division—First Prize: Samuel J. Cameron, Glasgow; Second Prize: Edward Gillespie, Govan; Third Prize: J. C. Ross, Sutherlandshire. First Class Certificates (in order of merit): William Robertson, Kilmarnock; Alexander Munro, Ross-shire; Andrew Stewart, Dalserf; William A. Milne, Glasgow, and John Morrison, India (equal); and Thomas Anderson, Newfoundland. Surgery (Professor T. Kennedy Dalziel, M.B.)—Winter Session, 1899-1900—Medal: Archibald Stevenson, Kilwinning. Certificates of Honour (in order of merit): First Class: Archibald Stevenson, Kilwinning; John Forrest, Glasgow; and Archibald Macmillan, Springburn; Second Class: William S. Cowin, Isle of Man; and Thomas Carruthers, Bridge of Weir. Midwifery and Diseases of Children (Professor John Edgar, M.A., B.Sc., M.B.)—Winter Session, 1899-1900—Medal: John Forrest, Glasgow. Certificates of Honour (in order of merit): First Class: John Forrest, Glasgow; Second Class: William S. Cowin, Isle of Man; Thomas R. Hunter, Sheffield; A. R. Moir, Glasgow; Thomas Anderson, Newfoundland; and Alexander Scoular, Carluke. Diseases of Women (Professor John Edgar, M.A., B.Sc., M.B.)—Summer Session, 1900—Medallist: Robert Ramsay, Glasgow. Certificates of Honour (in order of merit): First Class: Robert Ramsay, Glasgow; Alexander Scoular, Carluke; Reginald Nairn Dunlop, Glasgow; and Cecil R. Martin, Calcutta; Second Class: Richard H. Hunter, Sheffield. Medical Jurisprudence and Hygiene (Professor Carstairs Douglas, B.Sc., M.D.)—Summer Session, 1900—Medal: J. R. Smith, Greenock. Certificates of Honour (in order of merit): First Class: J. R. Smith, Greenock; A. Scoular, Carluke; J. B. Conner, Greenock; and C. R. Martin, Partick.

*London (Royal Free Hospital) School of Medicine for Women.*—Anatomy (Senior) (Examiner, Stanley Boyd, F.R.C.S.)—Prize: Miss Slater; Certificates: Miss Hill, Miss E. Watts, Miss Parson, Miss Francis, Miss Townsend, Miss Whitlock, Miss Chambers, and Miss Whittingham (equal), Miss Lamb, and Miss Iredell. Anatomy (Junior) (Examiner, Stanley Boyd, F.R.C.S.)—Prize: Miss Bolton; Certificates: Miss Kensington, Miss Fraser, and Miss Elgood. Practical Anatomy—First Prize: Miss Whitlock; Second Prize: Miss Slater. Physiology (Senior) (Examiner, Dr. Brodie)—Prize: Miss Slater; Certificates: Miss Chambers, Miss Elgood, Miss Iredell, Miss Thin, Miss Parson, Miss Sexton, Miss Watts, and Miss Whitlock; Physiology (Junior) (Examiner, Dr. Brodie)—Prize: Miss Bolton; Certificate: Miss Payne. Organic Chemistry (Examiner, Miss Evans, D.Sc.)—Prize: Miss Chambers; Certificates: Miss Hill, Miss Iredell, Miss Slater, Miss Watts, Miss Thin; Miss Kidd, and Miss Woodward (equal). Inorganic Chemistry (Examiner, Miss Evans, D.Sc.)—Prize: Miss Board. Biology (Examiner, G. P. Mudge, A.R.C.Sc.)—Prize: Miss Gibbon; Certificates: Miss Schiele and Miss Waller (equal), Miss O'Brien. Physics (for Preliminary Science Students) (Examiner, Miss E. A. Stoney)—Prize: Miss Hall; Certificate: Miss O'Brien. Physics (for L.S.A. students) (Examiner, Miss E. A. Stoney)—Prize: Miss Board and Miss Mann (equal); Certificates: Miss Kellgren and Miss Renouf. Medicine (Examiners, Miss Cock, M.D., and Dr. J. Walter Carr)—Prize: Mrs. Willey; Certificates: Miss E. M. Sharp, Miss H. G. Jones, and Miss Woodcock (equal). Midwifery (Examiner, Mrs. Scharlieb, M.D., M.S.)—First Evans Prize: Miss Shepheard; Second Evans Prize: Miss Scharlieb; Third Evans Prize: Miss Walters. Certificates: Miss Hickman, Miss Woodcock, Miss Fraser, Miss McDougall, and Miss K. Vaughan (equal), Mrs. Willey, Miss E. M. Sharp, Miss Gregg, Miss Chamberlain, Miss H. G. Jones, Miss Ivens, Miss A. E. Brown, Miss Mecklenburg, Miss Thorp, and Miss Burgess. Operative Midwifery (Examiner, Mrs. Stanley Boyd, M.D.)—Evans Prize of Five Guineas: Miss McDougall; Certificates: Mrs. Willey, Miss Hamilton, Miss Fraser, Miss Ivens, Miss Shepheard, and Miss S. Smith (equal). Entrance Scholarship for October, 1899, given by the Executive Council (value £30): Miss Sommer (Examiner, Mrs. Flemming, M.D.). Mackay Prizes, October, 1899: First Prize (value £20): Miss Maude Smith. Second Prize (value £20): Miss Hooper.

---

TYPHOID FEVER AT MERTHYR TYDVIL.—At the meeting of the Merthyr Tydvil Urban District Council held on Sept. 5th Dr. E. G. Simons, the medical officer of health, reported that since Jan. 1st, 1900, there had been 201 cases of enteric fever notified; this represented more than all the cases notified in the two preceding years. Dr. Simons added that Merthyr Tydvil had had five times as many cases per 1000 notified as the average of all other towns where notification was adopted.

# Medical News.

UNIVERSITY OF DURHAM.—At the First Examination for the degree of Bachelor in Medicine, held at the College of Medicine, Newcastle-upon-Tyne, in September, the following candidates satisfied the examiners:—

OLD REGULATIONS.

*Chemistry with Chemical Physics.*—Arthur Edward Clayton, L.R.C.P. and S., Edinburgh School of Medicine; John Spencer Hall, M.R.C.S., L.R.C.P., St. Thomas's Hospital; and James Sandison, M.R.C.S., L.R.C.P., London Hospital.

NEW REGULATIONS.

1. *Elementary Anatomy and Biology, Chemistry and Physics.*—First-class Honours: Thomas William Maddison, College of Medicine, Newcastle-upon-Tyne. Second-class Honours: Stanley Robson and Arthur Lewin Sheppard, College of Medicine, Newcastle-upon-Tyne. Pass List: George Nixon Biggs, St. Thomas's Hospital; Henry Mounsey Braithwaite, William Ernest Falconar, John Galloway, Norman Haliburton Hume, and Joseph Henry Lewars, College of Medicine, Newcastle-upon-Tyne; Aurelius Victor Maybury, Guy's Hospital; Ernest Martin, College of Medicine, Newcastle-upon-Tyne; Donald Murray Ross, University of New Zealand; and William Edward Stevenson, Samuel George Webb, and James Leslie Wilson, M.A., College of Medicine, Newcastle-upon-Tyne.
2. *Chemistry and Physics.*—Frederick Durnford Atkins, St. Thomas's Hospital; Llewelyn Alfred Henry Bulkeley and Arthur Budd, College of Medicine, Newcastle-upon-Tyne; Edmund Howard Barrett, M.R.C.S., L.R.C.P., St. Mary's Hospital; Herbert Christal and Hugh Boyd Cunningham, College of Medicine, Newcastle-upon-Tyne; Fred Thomas Holliway Davies, Mason College, Birmingham; Harold Edgar Featherstone, Albert James Gilbertson, Arthur Henry Hogg, George Errington Lloyd, Colin Francis Frederick McDowall, and Mary Raw, College of Medicine, Newcastle-upon-Tyne: Leslie Martin Rosten, St. Bartholomew's Hospital; Olga Schiele, London School of Medicine for Women; Frederick James Strachan, William Tait Sewell, and William Lister Tindle, College of Medicine, Newcastle-upon-Tyne; and Richard Le Geyt Worsley, M.R.C.S., L.R.C.P., L.S.A., St. George's Hospital.
3. *Elementary Anatomy and Biology.*—Cyril Claude Lavington, William Seymour, and William Frank Wilson, College of Medicine, Newcastle-upon-Tyne; and Ernest Young, St. Mary's Hospital.

VACCINATION PROSECUTIONS.—At the meeting of the Trowbridge board of guardians held on Sept. 5th it was decided that the vaccination officer should not prosecute vaccination defaulters unless authorised by the guardians.

THE LATE DR. S. GOURLEY OF WEST HARTLEPOOL.—The governors of the Hartlepool Hospital at their monthly meeting on Sept. 4th decided to place in the surgical ward a bronze medallion as a memorial of the late Mr. Samuel Gourley, M.D. Glasg., F.R.C.S. Edin., J.P. for the county of Durham. Dr. Gourley was for upwards of 30 years a member of the honorary medical staff of that institution. The medallion is the gift of his widow, Mrs. Gourley.

MILK-SUPPLY OF LLANELLY.—At the meeting of the Llanelly Sanitary Committee held on August 31st Mr. J. C. Hill, the newly-appointed veterinary inspector, reported that he had visited the majority of the rural retailers of milk and had not found any which met the requirements of the Local Government Board Order of 1885. All were deficient in either air-space, ventilation, light, flooring, or cleanliness. Within the urban area matters were not much better.

PRESENTATION TO A MEDICAL MAN.—At a recent meeting of the Sydney (Australia) City Council, the mayor of the city occupying the chair, the following resolution was unanimously carried: "That the retiring health officer, Mr. Gwynne-Hughes, be granted three months' leave on full pay, and that in accepting his resignation the council desires to place on record its high appreciation of his distinguished services to the council and to the citizens and that this expression of the council's wish be engrossed on vellum, signed by the mayor and town clerk, under seal, and conveyed to Mr. Gwynne-Hughes."

THE LATE MR. J. COUCH.—Mr. James Couch died at his residence, The Grove, Uplands, Swansea, on August 20th, in his seventy-fourth year. Mr. Couch, who was born at Swansea, received his medical education at University College Hospital, London, and took the qualifications of M.R.C.S. Eng. and L.S.A. in 1851 and 1866 respectively. He shortly afterwards commenced practice in Gower and then removed to Swansea where he for 34 years carried on an extensive practice. Mr. Couch was greatly respected in Swansea and much sympathy is felt there with his family. One of his sons is in practice at Swansea, and another, Mr. Llewelyn Couch, who was chief officer on the steamship *Mohegan*, only recently lost his life off the Manacles rock, Cornwall, while gallantly exerting himself to save the lives of the women and children.

## BOOKS, ETC., RECEIVED.

ALCAN, FELIX, Paris.
Le Phtisique et Son Traitement Hygiénique. Par E. P. Léon-Petit et Dr. Herard. 1895.

AMERICAN JOURNAL OF OPHTHALMOLOGY, St. Louis, Mo.
Original Contributions concerning the Glandular Structures appertaining to the Human Eye and its Appendages. By Adolf Alt, M.D., St. Louis. Illustrated. 1900.

BAILLIÈRE ET FILS, Paris.
La Pratique des Maladies des Yeux dans les Hôpitaux de Paris. Par P. Lefert. 1895.

BAILLIÈRE, TINDALL, AND COX, King William-street, Strand, London.
An Illustrated Dictionary of Medicine, Biology, and Allied Sciences. Fifth edition. By George M. Gould, A.M., M.D. 1900. Price 40*s.* net.

BOOT AND SON, 24, Old Bailey, London.
Anglo-Saxon Guide to the Paris Exhibition, 1900, with a complete List of the British Awards. New edition. 1900.

CHURCHILL, J. & A., Great Marlborough-street, London.
A Short Practice of Gynæcology. By H. Jellett, B.A., M.D. Dubl. Illustrated. 1900. Price 7*s.* 6*d.*
Southall's Organic Materia Medica. By J. Barclay, B.Sc. Lond., F.C.S. Sixth edition. 1900. Price 7*s.* 6*d.*
Ulceration of the Bladder, Simple, Tuberculous, and Malignant. By E. H. Fenwick, F.R.C.S. 1900. Price 5*s.*
A Manual of Midwifery. By A. L. Galabin, M.D. Cantab., F.R.C.P. Lond. Fifth edition. Illustrated. 1900. Price 15*s.*

CLARK, R. & R., Edinburgh.
The Climatic Conditions necessary for the Propagation and Spread of Plague. By Baldwin Latham, M.I.C.E., &c. Reprint. 1900.

DENT, J. M. AND CO., Bedford-street, Strand, London.
The Human Frame and the Laws of Health. By Drs. Rebmann and Seiler. Translated from the German by F. W. Keeble, M.A. 1900. Price 1*s.* net.
Ethnology. Translated from the German of Dr. Michael Haberlandt. By J. H. Loewe. 1900. Price 1*s.* net.

DIGBY, LONG, AND CO., Bouverie-street, Fleet-street, London.
The Latest Fruit is the Ripest, or Women's Work. By Fred. Jas. Gant, F.R.C.S. Second edition. 1898. Price 1*s.* 6*d.*

KIMPTON, H., High Holborn, London.
Essentials of Diagnosis, arranged in the Form of Questions and Answers. By S. Solis-Cohen, M.D., and A. A. Eshner, M.D. Second edition. Illustrated. 1900.
Diseases of Women: a Treatise on the Principles and Practice of Gynecology. By E. C. Dudley, A.M., M.D. Second edition. Illustrated. 1900. Price 21*s.* net.
A Manual of Clinical Diagnosis by Means of Microscopic and Chemical Methods. By C. E. Simon, M.D. Third edition. Illustrated. 1900. Price 18*s.* net.

LEADENHALL PRESS, 50, Leadenhall-street, London.
The Life of Sir Astley Cooper. By William H. Horrocks, F.R.C.S. 1900.

LEWIS, H. K., Gower-street, London.
A Handbook of the Diseases of the Eye and their Treatment. By H. R. Swanzy, A.M., M.B., F.R.C.S. Irel. Seventh edition. Illustrated. 1900. Price 12*s.* 6*d.*

# Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to* THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

BEALES, J. W. L., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the West Flegg Sanitary District of the East and West Flegg Incorporation, vice A. Crisp, deceased.

BENHAM, F. L., M.D. Lond., B.Sc., M.R.C.P., M.R.C.S., has been appointed a Public Vaccinator for South Australia.

BLACKER, ARTHUR BARRY, M.D., Durh., B.S., L.R.C.P. Lond., M.R.C.S., has been appointed Superintendent of the New X-ray Department at the Hospital for Consumption and Diseases of the Chest, Brompton.

BURKITT, G. O. E., L.R.C.P., L.R.C.S. Irel., D.P.H., has been appointed Honorary Surgeon to the Ear and Throat Department, the Perth Public Hospital, New South Wales.

CANN, T. M., M.R.C.S., has been re-appointed Medical Officer for the Workhouse by the Newhaven Board of Guardians.

CARY, ARTHUR JAMES, L.R.C.P., L.R.C.S., L.M. Irel., has been re-appointed Medical Officer for the Bleadon District by the Axbridge Board of Guardians.

EVANS, D. R. POWELL, L.R.C.P. Lond., M.R.C.S., L.S.A. Lond., has been appointed Medical Officer for the North Wimbledon District of the Kingston Union, vice O. W. Berry, resigned.

FINEMORE, J. H., L.R.C.P. Edin., L.S.A. Lond., has been appointed Medical Officer for Boonah, Queensland.

FOWLER, GEO., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Edin., has been appointed Assistant Resident Medical Officer to the Sheffield City Hospitals.

GAIRDNER, JAS., M.D. Edin., L.R.C.S. Edin., has been appointed Medical Officer by the Perth City Council, vice T. Crieff, resigned.

GOWLLAND, J. G. BLANTYRE, L.R.C.P., L.R.C.S. Edin., L.F.P. & S. Glasg., has been appointed Captain in the Army Medical Corps, Queensland Defence Force (Land).

HAWLEY, S. H., M.B. Durh., has been appointed Medical Officer for the First Sanitary District of the Walsall Union.

HIRST, W., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Assistant Resident Medical Officer for the City Hospitals by the Leeds City Council.

HOGG, C. A., Jun., M.B., C.M. Edin., has been appointed Senior Assistant Medical Officer in the Lunacy Department of the Hospital for the Insane, Gladesville, New South Wales.

HOGGAN, B. B., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Officer of Health for the Shire of Meredith, Victoria, Australia.

HOUSE, F. M., L.R.C.P. Lond., M.R.C.S., has been appointed Officer of Health to the Beverley Local Board of Health, West Australia.

JACKSON, H. W., M.B. Lond., L.R.C.P., M.R.C.S., D.P.H., has been appointed Medical Officer for the Middlesborough Central Sanitary District, vice A. Webster.

KIRK, T. D., M.D., M.Ch. Irel., has been appointed Medical Officer for the Forden Sanitary District of the Forden Union, vice T. Morgan, resigned.

MACDONALD, G. B. D., M.B., Ch.M. Aberd., has been appointed Officer of Health for the Shire of Waranga, Eastern Riding, Victoria, Australia.

MARSH, JAS., M.B., C.M. Edin., has been appointed Medical Officer of Health for the Atherton Urban District, vice J. T. Neech, resigned.

# Births, Marriages, and Deaths.

## BIRTHS.

BEALE.—On Sept. 8th, at Grosvenor-street, W., the wife of Peyton T. B. Beale, F.R.C.S., of a daughter.

BOWER.—On Sept. 7th, at Elton House, Gloucester, the wife of E. Dykes Bower, F.R.C.S. Ed., of a son.

DOBIE.—On Sept. 6th, at Hunter-street, Chester, the wife of W. Henry Dobie, M.B., M.R.C.S., of son.

MACAULAY.—On Sept. 2nd, at Milkwood-road, Herne-hill, S.E., the wife of Bryce Johnston Macaulay, L.R.C.P., L.R.C.S., of a son.

PEARSON.—On Sept. 8th, at Alicedale, Cape Colony, the wife of Maurice G. Pearson, M.B., B.Sc., F.R.C.S. Eng., of a son.

## MARRIAGES.

BIRD—BURRINGTON.—On Sept. 11th, at Wembdon, Bridgwater, by the Rev. George Trevor, vicar of Holy Trinity, Bridgwater, assisted by the Rev. J. M. Evans, vicar of the parish, George William Harvey Bird, M.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., second son of the late George Adam Bird of Glenthorn, Worcester, to Nellie, elder daughter of G. G. Burrington, of Westfield House, Bridgwater.

CROOKS—REID.—On Sept. 8th, at Weybridge parish church, James Crooks, M.D., of Faversham, Kent, to Grace Marion, second daughter of the late George Reid, of 79, Queen-street, Cheapside.

DAVIES—WOODFIELD.—August 29th, at St. Stephen's parish church, Redditch, Hugh Davies, F.R.C.S. Eng., M.B. Lond., B.S., Vale House, Greenwich, to Elizabeth Victoria, fifth daughter of William Woodfield, Elmsdale, Redditch.

GREENE—EVANS.—On Sept. 6th, at the parish church, Cheshunt, William Adams Greene, M.R.C.S., son of the late Henry Greene, of Brookville, Co. Clare, to Mabel Alice Evans, elder daughter of Nicholl Evans, M.D., J.P., of Cheshunt, Herts.

SEDGWICK—SCOTT.—On Sept. 5th, at the United Presbyterian Church, St. Vincent-street, Glasgow, Hubert Redmayne Sedgwick, M.A., M.B., B.C., of Kingston-on-Thames, to Euphemia Scott, daughter of the late James Wallace of Rutherglen.

SPON—ROBINSON.—On Sept. 5th, at St. Peter's Church, Drayton, Abingdon, Berks, Harry James Spon, M.R.C.S., L.R.C.P., D.P.H. Cantab., son of Francis Nicolas Spon, of Brockley, to Constance Mary, third daughter of the Rev. F. E. Robinson, M.A., Vicar of the parish.

WALKER—SHAW.—On Sept. 4th, at Jesmond parish church, Newcastle-on-Tyne, Frederick Septimus Walker, M.D., B.S., youngest son of the late Thomas Walker, J.P., of Staincliffe, Seaton Carew, to Florence Edith, youngest daughter of Benjamin Shaw, Singleton House, Newcastle-on-Tyne.

## DEATHS.

DAGG.—On Sept. 4th, at Park-crescent, Worthing, Trevor Augustus Dagg, M.R.C.S., L.R.C.P., third son of the late John Ross Dagg of Hatfield, aged 38 years.

HURTLEY.—On Sept. 3rd, 1900, at 25, Brunswick-place, Leeds, William Maw Hurtley, M.R.C.S. Eng., L.S.A., aged 44 years, eldest son of the late Thomas Hurtley.

MOORE.—On Sept. 6th, suddenly, Thomas Moore, F.R.C.S., of Lee-terrace, Blackheath, aged 62 years.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Short Comments, and Answers to Correspondents.

### THE SWANSEA HOSPITAL.

A SPECIAL meeting of the Board of Management of the Swansea Hospital was held on August 22nd, the chief business being the election of a chairman. Dr. H. A. Latimer, one of the consulting surgeons to the institution, was proposed and the nomination was duly seconded. Miss Dillwyn then moved as an amendment that another gentleman should be elected, on the ground that she was strongly opposed to the chairmanship being held by a medical man. She is further reported in the *Cambrian Daily Leader* as saying that "she thought they ought to consider the feeling of what she might call their outside constituents, who felt that there was already too much influence exercised in the management of the hospital by the medical profession." Mr. H. Goldberg seconded. The newspaper report is not very clear upon what those who were against a medical man being appointed said, but it is clear that some one made suggestions which were unfair, for towards the close of the meeting Mr. Ebenezer Davies is reported as saying that the remark that a medical man could not be expected to act fairly and honestly in the chair was an insult to an honourable profession. This same remark is also referred to by "A Friend of the Hospital," writing to the *Cambrian Daily Leader* of August 31st. Eventually Miss Dillwyn insisted on a division. The report does not say by how many votes her amendment was lost, but Dr. Latimer was eventually elected by 13 votes to 10. We are glad of this result, but we should like to understand how it is that ladies and gentlemen can allow themselves to make, or to assent to, charges of this description against the medical profession. Miss Dillwyn appears to think that a medical man cannot be trusted to adjudicate fairly in any matter where another medical man might be concerned. Objections might just as well be made to the appointment of a judge because some day he may have to try a member of the legal profession.

### A CONVALESCENT HOME FOR UPPER-CLASS CHILDREN.

*To the Editors of* THE LANCET.

SIRS,—I should be much obliged if you or any of your readers could tell me of a convalescent home for the children of gentlepeople. I have an idea that I at one time saw an advertisement of such an institution in THE LANCET. I am, Sirs, yours faithfully,

Leeds, Sept. 7th. ALFRED G. BARRS.

### SANITATION IN SCARBOROUGH.

*To the Editors of* THE LANCET.

SIRS,—Permit me to appeal to any medical man who may at the present time be visiting Scarborough and who may see this letter to observe the condition of the streets, particularly in regard to the sweepings that are allowed to lie and accumulate in all the thoroughfares. Although the town boasts so much of its sanitary arrangements the streets, even those where there is little traffic, smell strongly and refuse is allowed to lie for long intervals and helps to feed the boundaries of the pavements—in short, the gutters—with what ultimately becomes fine and filthy dust ready to be disturbed and blown about by any puff of wind. If some members of the medical profession would kindly note this discreditable and unhealthy condition that prevails in dry weather at the Queen of Northern Watering-places and make some reference to it in THE LANCET or direct to the officials in Scarborough they would perform a valuable public service.

I am, Sirs, yours faithfully,

Sept. 10th, 1900. Z.

### THE PLAGUE OR "TYPHUS BUBONICUS."

*To the Editors of* THE LANCET.

SIRS,—Searching for information on the above much dreaded disease I gather the following concise description from "Fagge's Medicine." The period of incubation is from two to seven days, followed by great malaise and depression. Intense pyrexia then sets in, which may be accompanied by violent delirium and rapidly assume a typhoid form. Death may occur at an early period, before there has been any symptoms characteristic of the malady. It may be preceded by hæmaturia, hæmoptysis, and black vomit. If life be prolonged to the second or third day there commonly appear one or more buboes in the groin, armpit, or neck. This formation is commonly attended by subsidence of the delirium and fever, profuse sweating, and the pulse falling to 90 or 100. The buboes break or are opened by a surgeon if they are tedious in healing. The prognosis is very fatal, seldom less than 60 per cent. of deaths. The treatment should consist of active stimulation and support. The buboes should be opened early. A second attack is comparatively rare. It is contagious and may be conveyed by articles of clothing—wool, silk, hair, books, &c. Warm and damp weather are favourable to it. It seems less apt to occur in persons over 50 years of age than in the young.

Were I called to undertake the treatment of cases of plague I should be inclined to administer the following, which I found useful in a very bad case of scarlet fever in Lazaretto in 1891. Solution of bichloride of mercury, two drachms; iodide of potassium, 10 grains; citrate of iron and ammonia, half a drachm; syrup, half an ounce; with water to one and a half ounces—one teaspoonful every two hours. Then when the temperature is down chlorate of potash and iron. The medication of these bubonic plague cases may be described as the use of the three B's—Brandy, Beef-tea, and Bichloride. The healing of the accompanying sluggish granulation might be expedited by the local application of equal parts of iodoform and oxide of zinc. The above is merely suggestive. The mode adopted by practitioners who have had experience in the east would be interesting and valuable.

I am, Sirs, yours faithfully,

Sept. 10th, 1900. INQUIRER.

## A SUBSTITUTE FOR BRANDY.

WE take the following note from the *League Journal*, a Glasgow temperance publication, of Sept. 8th. It forms part of an article headed "Our Women's Guild, Messages from Heart to Heart." The article, or perhaps we should say feature of the paper, is conducted by a Mrs. J. M. Oliver:—

> "Most members of 'Our Guild' will be glad to know of a very practical way of befriending the cause which lies so near, ay, and ofttimes presses so heavily, on our hearts. Some little time ago, when on a visit to a friend—a veteran temperance worker—she showed me the prescription for a 'Substitute for Brandy,' which was as follows:—
>
> SUBSTITUTE FOR BRANDY.
> In cases of fainting, severe pains, &c.
>
> EQUAL PARTS OF:—
> Strongest tincture of ginger,
> Sal Volatile, and
> Chloric ether.
>
> DOSE.—A *small* teaspoonful in about a tablespoonful of water.
>
> FOR CHILDREN.—Half the quantity.
>
> (*Any Chemist will make up a bottle of the mixture for 6d.*)
>
> This lady has had 2000 neat cards printed as above, which she distributes amongst those who are either in want of the prescription or who are able to reach others to influence them against resorting even in illness to alcoholic 'remedy' (?) which contains such incalculable possibilities for evil. I hope, nay, I *expect*, that every member of 'Our Guild' will forthwith cut out or copy this prescription, and then PASS IT ON.
>
> I took the prescription to a chemist of high standing and it is satisfactory to know that he gave it his unqualified approval. He said: 'It is a most excellent thing in *every way*.'"

We are sorry to dash Mrs. Oliver's hopes to the ground, but we should like to point out to her that brandy contains on an average about 50 per cent. of alcohol by volume. Now her prescription which is to influence others against resorting even in illness to alcoholic "remedy" is far more alcoholic than brandy; for tincture of ginger is practically pure alcohol with the essential portions of ginger dissolved in it; of nine pints and a half of sal volatile six pints are alcohol; and of 100 parts of chloric ether 95 are alcohol, so that her substitute contains quite 83 per cent. of alcohol by volume. Readers of "Mr. Ledbury" will remember Mr. Rawkin's favourite prescription, the Haustus Juniperi Comp., which the patient said was "blessed balm and their effects is peace." The composition was gin and tincture of cardamoms, but Mrs. Oliver's cordial would be even more efficacious.

## INSURANCE COMPANIES AND THEIR FEES.

*To the Editors of* THE LANCET.

SIRS,—A circular from an insurance company has just been issued to its medical examiners requesting them to subscribe to an agreement to a reduced scale of fees for examinations. Before this document be signed would it not be well for the examiners to confer on the matter?

I am, Sirs, yours faithfully,

Sept. 11th, 1900. ECLECTIC.

*** Yes.—ED. L.

## THE CLUB QUESTION IN LANCASTER.

THE medical men in Lancaster are at present engaged in an interesting contest with the members of various working men's clubs. In round numbers these have a membership of some 4000. At present the men pay 3*s*. 6*d*. per head per annum for medical attendance. This includes all medicines and surgical appliances. The work is divided amongst 12 practitioners. In June the latter, through the Lancaster Medical Book Club (a very old society, which has latterly been enlarged so as to include all members of the profession practising in the town), gave notice that after the end of the present year nothing less than 5*s*. per head per annum would be accepted for attendance on club patients. After some negotiations the clubs have offered 4*s*. "to finally settle the question so far as the present staffs are concerned." This offer was refused at a meeting of the Book Club held on Sept. 8th. The move is now with the workmen.

## "TIMES AND MANNERS."

IN the current number of the *Cornhill Magazine* Mr. A. D. Godley discourses in his usual pleasant manner upon the difference in manners between those of classic times and our own. Mr. Godley is at all events for the purpose of his verse *laudator temporis acti*. He points out how much happier from a medical point of view were the men of classic times as follows:—

> "Then should a too luxurious fare
> Sow sickness seeds (which was but seldom),
> A vow or inexpensive prayer
> At once effectively expelled 'em;
> Not yet the boons that science brings,
> No microbes yet could vex and plague you,
> At worst you died of common things—
> A fever or perhaps an ague.
>
> "How changed the modern's lot from yours!
> Daily do specialists affright his
> Inquiring mind with scores and scores
> Of things that end in death and-*itis*;
> Of ailments new with newer terms
> At Science feet we're always learning,
> With wholly unsuspected germs
> Awaiting us at every turning.
>
> "'Twas hard undoubtedly to be
> Beheaded by a tyrant's minions
> Because you chanced to disagree
> With his tyrannical opinions;
> Yet when I view the countless swarm
> Of troubles new that maim and kill us,
> Proscription seems a lesser harm
> Than medicine with a fresh bacillus!"

**COMMUNICATIONS not noticed in our present issue will receive attention in our next.**

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**MONDAY (17th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. A. Whitfield: Consultation. (Skin.)

**TUESDAY (18th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. J. Taylor: Consultation. (Medical.) 6 P.M. Dr. J. E. Squire: Class. Applied Anatomy. Demonstration I.

**WEDNESDAY (19th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. G. F. Still: Consultation. (Pædiatrics.)

**THURSDAY (20th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. Hutchinson: Consultation. (Surgical.)

**FRIDAY (21st).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. N. Maclehose: Consultation. (Eye.)

# EDITORIAL NOTICES.

**It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.**

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Lectures, original articles, and reports should be written on one side of the paper only,* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

# MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1900, which was completed with the issue of June 30th, and the Title-page to the Volume, were given in THE LANCET of July 7th.

### VOLUMES AND CASES.

VOLUMES for the first half of the year 1900 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

| FOR THE UNITED KINGDOM. | | TO THE COLONIES AND ABROAD. | |
|---|---|---|---|
| One Year ... ... ... | £1 12 6 | One Year ... ... ... | £1 14 8 |
| Six Months ... ... ... | 0 16 3 | Six Months ... ... ... | 0 17 4 |
| Three Months ... ... | 0 8 2 | Three Months ... ... | 0 8 8 |

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 3, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France,—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

# An Address

ON

# THE TREATMENT OF SOME COMMON DISEASES OF THE SKIN.

*Delivered before the South-Eastern Branch of the British Medical Association at Croydon on May 10th, 1900.*

BY PHINEAS S. ABRAHAM, M.D. DUB., B.SC. LOND., F.R.C.S. IREL.,

SURGEON TO THE HOSPITAL FOR DISEASES OF THE SKIN, BLACKFRIARS, AND DERMATOLOGIST TO THE WEST LONDON HOSPITAL.

GENTLEMEN,—When your chairman, Dr. Redfern, did me the honour to invite me to address you on this occasion it occurred to me that it might perhaps be more acceptable if I put together some rough notes of certain methods of treatment which I have found useful in some of the commoner diseases of the skin, rather than that I should inflict upon you an elaborate essay upon some special subject. I must first of all apologise for the very fragmentary nature of my communication, and secondly I must disclaim any idea of particular orginality in the measures that I am going to recommend. Many of the remedies that I shall mention are as old as the hills and I dare say are well known to you, and others are merely modifications of methods of treatment recommended by others. I was once present when an eminent specialist deprecated the admission of general practitioners into a certain special society on the ground that he did not see why specialists should give themselves away or give away their "tips," unless for a special fee. Fortunately, some of us still believe that we belong to a scientific profession and are sufficiently imbued with the Hippocratic spirit to be above such contemptible small-mindedness. At any rate, most of us specialists are always ready to impart all we know—little though it may be—to any brother practitioner who may consider it worth his while to listen to us either at the hospital or elsewhere.

I propose on this occasion to speak particularly upon the treatment of the following common diseases—eczema, psoriasis, impetigo, acne, and ringworm.

## ECZEMA.

That the numerous cases of cutaneous eruptions which are included under this name have more than one pathological cause most dermatologists are agreed. There can be no doubt, however, that the ubiquitous microbe is at the bottom of many of them, and it is to my mind more than probable that there is more than one microbe the growth and development of which in the skin will produce the inflammation, irritation, exudation, and exfoliation which are more or less characteristic of "eczema."

As with other microbic infections, moreover, another factor is necessary for the production of the disease: the micro-organisms will not flourish if the soil or cultivating medium—i.e., the tissues and juices thereof—be not suitable. Some of the modern dermatologists, especially on the continent, are, I fancy, rather inclined to ignore this latter factor and to depend too much upon purely external applications in the treatment of eczema. On the other hand, there can be no doubt that the older practitioners relied too much on internal medication in this and in many other diseases of the skin. I feel sure that in most cases the best results are obtained by simultaneous external and internal remedies Our aim should be to get the whole system—all the organs of the body—in a thoroughly healthy condition as well as to destroy the microbes or prevent their growth, and we must see to the digestion, to constipation, to the kidneys, to the circulation, and even to the nervous system—to everything, in fact, which may directly or indirectly influence the condition of the tissues and fluids of the skin.

I frequently give with benefit an iron and magnesia mixture—e.g., the mistura ferri aperiens of most hospital pharmacopœias—with a little nux vomica as a digestive tonic, or sometimes an alkaline bitter mixture with an aperient if necessary, and if able I regulate the diet as far as possible. As a rule I recommend simple, plainly-cooked food, the avoidance of much sugar, tea, strong coffee, pastry, cheese, beer, acid and sweet wines, or much alcohol in any form. Externally, the applications will vary with the form of the eczema, its acuteness, extent, position, &c. In acute inflamed cases, antisepsis, protection, and reduction of inflammation and exudation are to be aimed at, and either powders, pastes, liniments, ointments, or zinc gelatins may be employed. Many cases do well with what we at Blackfriars call the "unguentum hydrargyri cum plumbo," which contains 10 grains of acetate of lead, 10 grains of calomel, 20 grains of oxide of zinc, 20 grains of ointment of nitrate of mercury, and one ounce of vaseline. But occasionally an eczematous skin will not stand an ordinary ointment, and a modification of Lassar's paste may then be tried—e.g., three drachms each of zinc oxide and starch, 10 grains of salicylic acid, and one ounce of vaseline, or a calamine liniment containing one drachm of carbonate of zinc and half an ounce each of olive oil and limewater. When the weeping and inflammation are excessive a powder thickly dusted on is sometimes effective—e.g., half an ounce of starch, two drachms of oxide of zinc, and one drachm of powdered borax or boric acid. Many cases of acute eczema which have resisted other applications have yielded in my hands to the zinc-gelatin treatment (of Pick and Unna)—viz., half an ounce of gelatin, three drachms of oxide of zinc, one ounce of water, and half an ounce of glycerine, and I generally add 10 minims of ichthyol. The mass melted in a glue-pot and painted over forms an elastic, protective, and soothing covering. In all cases, immediately before applying any of the above, I order the parts affected to be well bathed with a very dilute antiseptic lotion. In preference I use a lotion containing half a drachm of creolin to a pint of soft boiled water, because it is effective as an antipruritic as well as being an antiseptic and—an element of importance in hospital practice—because it is inexpensive. Other weak antiseptic lotions are no doubt equally as good.

In dry eczemas and where there is but little inflammation, tarry ointments are usually very efficacious. Our favourite one at Blackfriars is the so-called "unguentum petrolei compositum." This contains half a drachm of alcoholic solution of coal tar, 10 grains of ammoniated mercury, and an ounce of vaseline. Creolin is sometimes with benefit substituted for the alcoholic solution of coal tar and I dare say that the liquor picis carbonis would also do.

As with the acute eczemas I always advise bathing the parts affected with a weak tarry lotion before applying the ointment night and morning, or even, if the eruption be extensive, a tepid bath containing from half a drachm to one drachm of creolin or other tar product to about six gallons of water. Soap is generally detrimental in eczemas, especially in the acute form, and I frequently recommend a muslin bag filled with bran to be used as a substitute. A warm sitz bath night and morning with rather more creolin in it—say one drachm to two gallons—I have found very useful in obstinate cases of eczema of the perineum and anus. In these cases, too, I have sometimes found the addition to the tar ointment of 10 grains of sulphur or 25 grains of ichthyol to be of good effect. This is applied immediately after the bath.

In eczemas of the limbs I keep the ointment bandaged on, and I am sure that careful bandaging of the legs from the foot to the knee is an important adjunct to the treatment, especially when varicose veins are also present, as they often are. There is one matter that I should like to point out in the treatment of eczema. It is a mistake to use strong ointments—a fact that, I believe, was first recognised by the elder Startin, the founder of Blackfriars Hospital for Diseases of the Skin, and which has not yet been grasped by the editors of the British Pharmacopœia, for the officinal ointments therein set down are mostly too strong in skin cases.

## PSORIASIS.

Although I regard the constitutional element in psoriasis of even more etiological importance than in eczema, seeing as we do among its other features its tendency to occur in several members of the same family, and in gouty and rheumatic subjects, I have come to the conclusion that external treatment is, comparatively even, of much greater use in this disease. As with eczema we ought to consider the state of the internal organs as well as any "diathesis" which may be indicated. I believe that the older practitioners were often right in giving alkalies and diuretics in these cases, but I have long become convinced that there is

no particular drug administered internally which can fairly be regarded as a specific for psoriasis. As for arsenic, I consider that its vaunted specific efficacy in the treatment of this disease is little short of a medical myth. I could produce notes of numerous cases in which its persistent exhibition for years has produced no effect either in removing the efflorescence, or in preventing its recurrence after its removal by external treatment. If, as perhaps happens occasionally, the patches disappear during a prolonged course of the drug, it has only been, according to my view, either after the patient has been made very ill, the nutrition of all the tissues having suffered—the skin with its patches of psoriasis along with the rest—or from the effect of concomitant measures. We frequently, indeed, see the efflorescence of psoriasis temporarily vanish during some other intermediate severe affection—gastritis, fevers, influenza—and I have even seen the spots go when a patient has meanwhile contracted syphilis.

Thyroid gland is another much vaunted drug which I have also discarded in the treatment of psoriasis. Some years ago I tried it extensively in the disease, and came to the conclusion that although in a few cases it undoubtedly caused the exfoliation and disappearance of the spots, in the majority it had no effect, and, indeed, frequently made the patients very ill without doing much good to the psoriasis. Even in those cases in which the results were good the rapidity of cure was by no means greater than with the ordinary external methods of treatment, nor was there any less tendency to recurrence. The external application of chrysarobin undoubtedly removes the efflorescence quicker than anything else. As an ointment, however, it has its drawbacks—ruining the patient's clothes, and producing severe and disagreeable erythema in tender parts and inflammation of the eyes if accidentally carried thereto. I use it now always in the form of a solution, to be rubbed in only on the patches which are situated on the extensor surfaces where the skin is less tender—e.g., 40 grains of chrysarobin, 10 grains of salicylic acid, and one ounce of solution of gutta-percha (in chloroform), this forms a film which, when dry, does not stain the linen. As it peels off it is to be replaced every day or two—generally until an erythematous blush appears around. A more or less saturated solution of chrysarobin in benzine, rubbed into the patch, and then when dry painted over with collodion or the liquor gutta-percha is also very effective. For other parts of the body I usually order a strong tar or creolin ointment—e.g., one drachm of creolin, 10 grains of ammoniated mercury, and an ounce of vaseline, often also with the addition of from 10 to 20 grains of salicylic acid. If possible I make the patients soak themselves for a quarter of an hour or 20 minutes every night in a warm bath containing creolin and then thoroughly inunct the patches with the ointment.

For psoriasis of the scalp, the most efficacious treatment in my experience is an ointment containing a drachm of ammoniated mercury and three and a half drachms each of soft soap and vaseline to be well rubbed in every night. By these measures thoroughly carried out the most inveterate cases can, I believe, be "cured" in a few weeks; and I am not aware that the affection then shows more tendency to recur than after any other method of treatment. Indeed, I know several old patients who were so treated who have had no return of their psoriasis for many years.

### IMPETIGO.

Everyone who visits the out-patient department of the West London Hospital is surprised at the enormous number of cases of impetigo that we see there and I have no good explanation of the fact that the disease is so prevalent in Hammersmith and the neighbourhood. In most skin clinics the cases of eczema are by far the most numerous; at Hammersmith the impetigo cases certainly predominate. Fortunately it is a disease easily cured and by the good old-fashioned remedy—ammoniated mercury ointment.

I do not approve of the crusts being removed by poulticing. Warm oil or a weak, warm antiseptic lotion ought to be sufficient. I generally order a weak creolin lotion for this purpose, the ointment to be applied immediately afterwards and re-applied night and morning. If pediculi are present, as is usually the case in the heads of our London School Board children, I recommend a thorough nightly washing with soft soap and hot water immediately before applying the ointment. If this treatment be kept up for some weeks the young pediculi are dealt with as they come forth from the nits and the pediculosis is soon eradicated.

### ACNE.

This is another common affection which in my experience can be cured with certainty and in a comparatively short time by a judicious combination of internal and external remedies. I believe that unless the skin is in a more or less unhealthy state the pus and comedo-producing organisms do not perform their nefarious function. The majority of acne patients will give some indication of dyspeptic trouble, constipation, &c., and the rosaceous cases particularly of flushings of the face, &c., and not infrequently they give a history of their faces being worse at the menstrual period. Most of them I find to be benefited by the tonic and aperient iron and magnesia mixture between meals, others by an alkaline bismuth mixture before food. In all cases I recommend the application to the spots every night of the compound sulphur ointment of Blackfriars which contains 30 grains of sulphur, 10 grains of ammoniated mercury, 10 grains of sulphide of mercury, and an ounce of vaseline, slightly varying the quantities in particular cases and adding oxide of zinc if there be much inflammation. Occasionally the old sulphur and lime-water lotion does well, but I find as a rule that the above ointment does better. Before its application I make the patients bathe the face with hot water and a 10 per cent. ichthyol soap well lathered on. This is to be done again in the morning and very often I tell them to keep the lather on for as long as possible. But a still more important part of the treatment, in my opinion, is the cautious application to each pimple of the tiniest driplet of pure carbolic acid, just liquefied with a little water, as recommended many years ago by Dr. Walter Smith of Dublin. As a rule, one application aborts and cures the pustule. The rapid efficacy of this application is particularly apparent in those very bad cases of recent alcoholic acne. In indurated cases where subcutaneous abscesses have formed and where the pustules are large and deep I puncture them, and with a small blunt-pointed hypodermic syringe needle, with the orifice apical. I thoroughly wash out the cavity with some antiseptic lotion—1 in 1000 sublimate, 1 in 20 carbolic, izal, or chinosol. I do not think it matters much which—in fact, I treat it as one would treat antiseptically an ordinary surgical abscess. I think it always well to remove as many comedones as possible in acne cases, and for this I use the comedo extractor which has been made for me by several London instrument makers.

### RINGWORM.

As we all know, many cases of ringworm of the scalp can be easily cured by the application of iodine tincture and liniment, Costa's paste, turpentine, or even common ink. When, however, the fungus gets deep down into the hair follicles it is not so easy to get at, and the case even in the most experienced hands may last for years. During the past 15 years I think I have experimented with most of the methods, and the number is legion, that have been proposed for the treatment of ringworm. I am now advising the following measures in the majority of cases. The scalp to be shaved every fortnight and calico skull caps to be worn day and night, an ointment consisting of one drachm each of pure carbolic acid and salicylic acid to the ounce of vaseline to be well rubbed in with a stiff brush night and morning over the patches, and the rest of the scalp slightly smeared over with the same ointment. Twice a week I have the scalp lathered with hot water and a soapy mixture containing two ounces of soft soap, two drachms of glycerine of carbolic acid, and two drachms of glycerine of boric acid, to be followed immediately by an application of the ointment. Once or twice a week, if possible, I use immediately after the washing my special pump which forces in by the atmospheric pressure any parasiticide liquid which you may wish to use. The area of scalp beneath the bell simply becomes impregnated with the fluid, making the soil very unpleasant at least for the undesirable trichophyton. I generally employ pure creasote and sometimes equal parts of ozonic ether and guaiacol which penetrates readily. Before using this machine it is as well to remove as much fat as possible from the follicles by swabbing the patch with ether. Many cases that have resisted other methods of treatment for years have in my hands yielded to this.

### CONCLUSION.

I think, gentlemen, that I have now wearied you enough, but before concluding I should like to express my opinion

that we are in this country in a great degree handicapped in the treatment of diseases of the skin from the fact that we cannot always have the various necessary measures thoroughly carried out. It may be all very well for the hospital patients and for very wealthy people who have the time to devote and who can afford to go to the West End nursing homes. In a large number of cases, however, the initial prescription and the occasional visit to the skilled practitioner are deemed sufficient; the circumstances of the patient's home rarely lend themselves to thorough inunction, suitable baths, &c., and, indeed, are seldom adequate, and the result often is that the case "hangs fire." The continental patient suffering from a disease of the skin is, on the other hand, better off. He goes to an experienced special practitioner who admits him into his private hospital at a cost varying according to his means, is seen and dressed every day by the practitioner himself or by his assistants, with frequent modifications of treatment as indicated, and I am obliged to admit is often cured quicker and more satisfactorily than he would be in this country. I have myself more than once—an admission which I regret to have to make—felt constrained to send patients who were above the hospital class to Aix la Chapelle, to Hamburg, and to other places abroad, because I conscientiously knew that their cases would be more thoroughly dealt with and at less expense than in a London nursing home. I have only now to thank you for listening to these very desultory remarks. I hope, however, that some of the measures which I have mentioned may prove of use to some of you.

# THE ETIOLOGY OF RHEUMATIC FEVER.

BY FREDERICK J. POYNTON, M.D., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, AND CASUALTY PHYSICIAN TO ST. MARY'S HOSPITAL;
AND
ALEXANDER PAINE, M.D. LOND.,
ASSISTANT BACTERIOLOGIST TO ST. MARY'S HOSPITAL.

THE etiology of rheumatic fever has proved to be a problem of such complexity that it is necessary to state at the very outset of this paper the scope and object of the research. The various results that had been already obtained by investigators were in themselves our first difficulty, for they necessitated the employment of widely different methods to enable us to cover the ground already traversed. Our first intention was to obtain, if possible, some definite facts from which as a basis we might make further advances, and the discovery and isolation of micro-organisms in the form of diplococci in eight successive cases of rheumatic fever afforded us this opportunity. When we had obtained these diplococci in pure culture Mr. H. G. Plimmer undertook a series of inoculations into animals and the results that followed provided us with further data. Finally, microscopic investigations of the human and animal tissues have been another source from which we have obtained facts which we believe to be of considerable importance. The methods that have been used and the conclusions that have been obtained from these three sources are detailed in this paper, together with a brief historical survey of the work of others upon this subject.

There are many points of interest that are suggested by these results; but the most important fact deducible from our researches, as detailed below, is *that this diplococcus which we have isolated is a cause of rheumatic fever*. It is to this conclusion that our results seem irresistibly to lead. We are not, however, in the face of the results of others, in a position to state that these diplococci are invariably present in rheumatic fever, nor are we able to claim that they are the only cause of this disease.

## AN OUTLINE OF THE HISTORY OF THE BACTERIOLOGY OF RHEUMATIC FEVER.

Before giving an outline of our results a historical survey of the subject is appended sufficient to indicate the various views that are, and have been, held, and to do justice to others who have made investigations upon this question. This outline cannot claim to be exhaustive, but it does, we hope, give due credit to those who have already expended much labour in attempting to discover the true cause of rheumatic fever. In 1892 Fraenkel [1] called attention to a paper by P. Guttmann upon the etiology of rheumatism and its complications. Guttmann described a case of very acute rheumatism with exudative pericarditis complicated by abscesses in the kidneys and muscles from which the staphylococcus pyogenes flavus was isolated. This micro-organism was obtained from the pericardial exudation and the abscesses but not from the joints. Guttmann expressly stated that this was not a case of true rheumatism, nor did he consider this organism, if it were the cause of the rheumatism in this case, to be the sole cause of rheumatic fever. Leyden also concurred with this opinion. In the same year Sahli [2] discovered the staphylococcus pyogenes citreus in the synovial membrane of the joints in a case of rheumatic fever and also in the pericardial exudation. He considered rheumatic fever to be due to a staphylococcus infection but left it an open question as to whether or not the condition was due to an attenuation of the organism. Netter [3] also isolated a streptococcus from a case clinically resembling rheumatic fever but following acute suppurative otitis media. Lanz [4] in 1893 published a paper upon experimental results connected with suppurative polyarthritis. From the pus of an abscess of the brain operated on by Kocher he isolated a bacillus. This on intravenous injection into rabbits caused death in 23 days. Suppurative polyarthritis resulted and the bacillus was again isolated from the joints. To this organism he gave the name of bacillus pyogenes fœtidus liquefaciens. In 1894 Maragliano [5] obtained diplococci and staphylococci from a case which commenced clinically as rheumatic fever and ended as a septicæmia. This writer also insisted upon the relationship between rheumatic fever and suppurative affections. At this time Chvostek [6] and Singer [7] published papers upon the micro-organisms found in the urine of patients suffering from rheumatic fever. Singer found as the result of the examination of the urine in 17 cases that the staphylococcus pyogenes aureus was frequently present, and when present was to be found in considerable numbers, but became less as the disease declined. He associated this occurrence with the rheumatic process. Chvostek, though recognising the importance of Singer's investigation, doubted the validity of his conclusions. Dana [8] in 1894 isolated a diplococcus from a case of chorea following rheumatism. The organism was found in the meninges of the brain and spinal cord. Charrin [9] found streptococci in cases of rheumatic fever. Sacaze [10] made the interesting suggestion that some external wound, often insignificant, might be the site of infection in rheumatic fever. In 1896 Lubarsch, [11] in a paper upon the streptococcus group and the diseases caused by them, alludes to an exhaustive paper by Buss of Bremen upon the relation of angina faucium to rheumatic fever. Buss [12] in this paper came to the conclusion that the throat and intestines are in many instances the sites of the entrance of the rheumatic infection.

The clinical importance of the angina faucium that occurs in rheumatism had long been recognised. It was mentioned by Trousseau [13] in his "Clinical Medicine" and Dr. Kingston Fowler [14] in 1880 published an account of 20 cases of acute rheumatism ushered in by tonsillitis; Dr. Cheadle [15] further insisted upon this clinical fact in 1888 in the Harveian Lectures upon the rheumatic state in childhood.

Achalme [16] introduced a new field for investigation by a series of papers upon the bacteriology of rheumatic fever dating from 1891. He discovered a bacillus in the blood of patients who succumbed to rheumatic fever and by his subsequent researches confirmed this observation. His results

are of such importance that some space must be devoted to an account of them. The bacillus resembled that of anthrax both in size and in the blunt ends, but varied considerably in size though not in thickness in different media. It occurred in the blood in scanty numbers and was grown anaerobically, not aerobically. A mixture of milk and beef-tea was the medium used, but it grew well upon alkaline bouillon made from horses' flesh. The anaerobic tubes were not opened for from eight to ten days. Solid media were not well adapted for studying the properties of this bacillus. When growing in alkaline bouillon gas bubbles and a turbid deposit appeared within 12 hours. The bacillus stained well with all the aniline dyes but best with faintly alkaline methylene blue. In 1897 Achalme[17] published a detailed account of his researches upon this bacillus with clinical histories of nine cases in which it had been found. The results of injections into animals were also given. Sanious exudation at the sites of inoculation was a prominent feature and in the most severe cases death occurred from septicæmia. A true picture of rheumatic fever, as it occurs in man, did not appear to result in animals thus infected. The results that Achalme obtained have naturally aroused considerable interest, and it is remarkable that an organism of such a size and one that stains so well should have been overlooked by those who have investigated the tissues in rheumatic fever.

Thiroloix,[18] following Achalme's investigation of this bacillus, fully confirmed his results in a series of papers. In addition, in five cases of rheumatism he obtained this bacillus and inoculations into rabbits gave the entire picture of rheumatic fever. Again, he obtained the organism from the blood and pleural effusion in one case of rheumatic fever, and this produced in guinea-pigs sanious exudations and in rabbits a heart but not a joint inflammation. In two later cases he obtained the latter also. Triboulet[19] in a case of rheumatic fever found a bacillus resembling that described by Achalme. But later Triboulet and Coyon[20] found a diplococcus in five cases. In two of these the diplococci were associated with Achalme's bacillus, and they argue that severe and complicated cases are due to Achalme's bacillus together with the associated diplococci, whereas the simple cases of rheumatism are due to the diplococci alone. Riva[21] in 1897 isolated a specific micro-organism from eight cases of rheumatic fever. The organism varied much in shape in different media and occurred in both coccal and bacillary forms. He made use of a complicated medium slightly acid in reaction, an essential constituent of which was the synovia from the joints of horses. In 1898 Apert and Triboulet[22] obtained some remarkable results by the inoculation of a rabbit with a diplococcus isolated from the blood of a patient suffering from rheumatic fever. 20 days afterwards they found thickening of the mitral valve with hypertrophy and dilatation of the chambers of the heart and excess of clear fluid in the pericardium. There was also pleurisy but no peritonitis. None of the joints were affected. This diplococcus was identical in character with that found in 11 other cases of rheumatic fever. In spite of the absence of any joint lesions Triboulet considered this organism to be specific. Injected under the skin Apert found the diplococcus produced a local induration. Bettencourt[23] in 1898 supported the researches of Achalme and Thiroloix. Gustav Singer[24] in a monograph gave the results of an extensive investigation of many cases of rheumatic fever and was led to the conclusion that acute rheumatism is not a specific disease but owes its origin to streptococcal and staphylococcal infection. In 1899 Kronenberg,[25] in a paper upon angina faucium in acute rheumatic fever, expressed doubts that rheumatism is a disease *sui generis*, but he thought rather that it was a peculiar reaction of the joints and other tissues to a series of bacterial influences—as, for example, the gonococcal, the streptococcal, and the allied infections. In 1899 Westphal, Wassermann, and Malkoff published a paper, "Ueber den Infectiösen Charakter und den Zusammenhang von Acutem Gelenkrheumatismus und Chorea"[26] Westphal narrated the history of the case from which the material was obtained. It was a severe case of chorea that followed acute rheumatism, occurring in January, 1899. Violent delirium with hyperpyrexia and collapse resulted in death on Feb. 24th. The necropsy a few hours later showed minute vegetations upon the mitral valve and parenchymatous nephritis; there was no suppuration. Cultures were made from the heart's blood, pericardial fluid, mitral valve, spleen, and brain. Wassermann, after alluding to the researches of Löffler, Michaelis, Eberth, Litten, and von Leyden, described the bacteriological results. A diplococcus resembling morphologically that found by Von Leyden in rheumatic valvulitis was isolated and in 80 rabbits produced fever and multiple arthritis. This organism appeared as a diplococcus in the tissues but grew in culture as a streptococcus. The number of micro-organisms in the tissues of the patient was very small. It required a higher degree of alkalinity than that of the ordinary media, upon which it refused to grow. The incubation period was from three to ten days. All the tissues of the joint were inflamed and in the fluid of those which had been affected longest there was a considerable number of leucocytes. In addition there was exudation in the tendon sheaths and bursæ. The micro-organism was found in the arthritic exudation and cultures from the animals reproduced the disease in other animals. Litten[27] at the same date isolated from a malignant form of rheumatic endocarditis (non-suppurative) a very minute streptococcus which was fatal to mice and guinea-pigs but rapidly lost virulence upon culture. In a footnote to his paper he is of opinion that Westphal and Wassermann have probably found the true excitant of acute rheumatism but suggests that there may possibly be more than one. It appears to us that this diplococcus must resemble, if not be identical with, that investigated by Triboulet in 1897.

This brief survey is sufficient to show how complicated and uncertain the present position of the bacteriology of rheumatic fever still remains. In the following short analysis of the various hypotheses we hope to make clear that view of the subject which seemed to us the most probable and to indicate the direction in which our researches tended. There may be some who still decline to regard rheumatic fever as a microbic disease, but we have started upon the assumption that it is an infection, being led to this conclusion by the results of clinical and pathological experience and teaching. The broad clinical view of rheumatism which has been taken by such authorities as Dr. W. B. Cheadle, Dr. Thomas Barlow, Dr. D. B. Lees, and Dr. A. Garrod in this country appears to us to support this hypothesis very strongly.

*View No. 1.*—Allowing that the cause of rheumatic fever is microbic, one view that has met with considerable support maintains that there is no specific micro-organism, but that rheumatism is but a form of septicæmia which owes its origin to staphylococcal and streptococcal infection. The close analogy between the rheumatic processes and those of pyæmia and the frequent discovery of staphylococci and streptococci in cases of rheumatic fever have naturally led to this view. It is undoubtedly a very important one and involves bacteriological and clinical problems of the greatest difficulty. It raises the question of what is really the definition of the specificity of an organism and deals with what is still an unknown quantity—viz., the extent of variability that is possible in a micro-organism and its results under varying conditions of virulence and resistance. We have fallen back upon the teaching of clinical medicine and pathology as our guide in this matter Rheumatic fever as we meet with it in England is a common disease with, on the whole, very definite characteristics. However virulent the disease it may be practically asserted from the clinical standpoint that suppuration does not occur. Many cases die in the course of a year with acute cardiac inflammation, yet the heart and other viscera are not in a condition of suppuration. We were inclined to expect that an organism the cause of rheumatic fever if isolated and inoculated into suitable animals would produce in them a condition resembling the

rheumatic fever of man in the absence of multiple foci of suppuration. That this limit may be overstepped both in man and animals under exceptional, and perhaps as yet unknown, circumstances seemed to us very probable, but the general and average result that we expected was a condition in which the absence of suppuration would be a prominent feature.

*View No. 2.*—Another view maintains that the cause of rheumatism is a specific diplococcus. It is to this view that we inclined, though we would repeat once more that the definition of what is meant exactly by "specific" involves many difficult problems concerned with the virulence of the infection and nature of resistance.

*View No. 3.*—A third view maintains that the cause is a specific bacillus. This view is a decidedly simpler one, if it were proved to be true. If the bacillus, as, for example, that described by Achalme, be found to be invariably present in rheumatic fever it is easily distinguishable from the staphylococci and streptococci that are found so frequently associated in rheumatism, and its morphological characters alone would be of the greatest assistance in establishing the truth of its claim.

*View No. 4.*—A fourth view raises the question of a mixed infection of bacilli and cocci, an analogy to which is readily supplied by diphtheria. To us this view appeared one of great difficulty and withal unsatisfactory. There can be no reasonable doubt in the face of the numerous investigations that have been made that cocci of some form or other are frequently present in rheumatic fever and hence the origin of such a view as the one under consideration. Nor can there be reasonable doubt that cocci are capable of producing polyarthritis, valvulitis, pericarditis, pyrexia, sweating, infarction, and other manifestations closely resembling those of rheumatic fever. If, then, both the bacilli and cocci are needful to produce rheumatic fever the association must be a mysterious one. If the cocci are the cause of the symptoms it is possible that they are restrained from causing suppuration by the presence of the bacilli. If the bacilli are the cause of the symptoms it is possible that they produce them only when associated with these cocci, though this is difficult to realise when it is remembered that these cocci may themselves produce almost similar lesions.

*View No. 5.*—This last view holds that rheumatic fever is not a disease *sui generis* but a particular reaction of the tissues to varied infections. We thought that the remarkable constancy of the clinical symptoms of rheumatic fever, as met with certainly in England, were much against its being a condition that would result from many and varied infections.

Not only is there this diversity of opinion regarding the organism, but opinions differ also as to the explanation of the way in which the symptoms are caused. Does the micro organism remain localised to one spot—for example, the tonsils—and pour its toxins into the system, giving rise in this way to carditis, arthritis, nodules, and other local lesions? or is it widely distributed and present in the local lesions? We inclined to the belief that the organism was to be found in the local lesions, though perhaps only with great difficulty. The probability of its occurrence at these sites seemed to us to be indicated by the analogy of pyæmia.

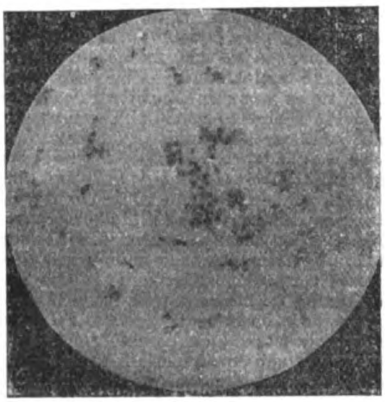
To summarise our point of view at the start of this investigation we thought it most probable that the organism would always be present in cases of rheumatic fever; that it would be capable of isolation; that it would produce the symptoms of rheumatic fever in a suitable animal; and that it would probably exhibit some definite peculiarities upon culture. We also thought that it would be present in the local lesions and that the infection would be a simple and not a mixed one. The analogy that there appears to be between rheumatic fever and septic infections pointed to the infection being coccal rather than bacillary. We were, however, naturally influenced by the positive results of Achalme and his corroborators, and their results appeared to us so definite that we gave especial attention to the discovery of this bacillus in our earlier cases.

### THE OUTLINE OF THE INVESTIGATION.

After this brief consideration of these various theories we give in outline the results of our investigation, then in detail the methods, cases, and bacteriological investigations, and finally a short summary of the facts which have been established, with some concluding remarks.

In January, 1899, we undertook the study of the bacteriology of rheumatism with the intention of confirming, if possible, the results obtained by Achalme. For some long time we were influenced by this intention, but finally abandoned the attempt, having failed to obtain a bacillus morphologically resembling anthrax either in culture or in the tissues. On the other hand, we obtained later in eight successive cases a diplococcus which grew in liquid media in streptococcal chains. This organism did not thrive upon ordinary agar or serum agar, and though we were able to grow it eventually upon blood agar it appeared to grow best in a liquid medium of milk and bouillon rendered slightly acid with lactic acid. Upon three occasions we isolated the organism in pure culture from the blood of patients during life who were suffering from acute rheumatic pericarditis. It was also obtained from the pericardial fluid after death and from the valves and lastly from the throat of a rheumatic patient. In our first two cases we did not investigate the characteristics of the diplococcus and in one recent case it was associated with numerous small bacilli. In one case a sarcina was present as a contamination. In five of the eight cases it was in pure culture. When we became acquainted with the researches of Wassermann, Westphal, and Malkoff, it seemed clear that this was the organism they had described, and we feel no doubt that it is identical although there have been certain differences in the results that we have obtained. As stated above, we succeeded best in cultivating it in an acid medium and have not had success with a strongly alkaline medium, as recommended by Wassermann, though we are in doubt as to the exact degree of alkalinity that Professor Wassermann found to be most suitable, about which point he made no definite statement of which we are aware. It is of considerable interest that we succeeded in growing the diplococcus on two occasions in the pericardial exudation and noticed in one of these instances an increase in flakiness of the fluid. On both these occasions the pericardial fluid was distinctly acid, so that there is this proof that the organism will grow in an acid medium. The demonstration of these diplococci in films from the pericardial fluid after incubation is very definite, and we have also found them in scanty numbers in films from recent vegetations, from unincubated pericardial fluid, from blood from the heart wall, and from the throat. Their demonstration in the tissues is by no means easy. We have, however, demonstrated them unmistakably in the tissue of a rheumatic nodule and in the valves, pericardium, and tonsil. Mr. H. G. Plimmer undertook a series of inoculations for us from the pure cultures that had been obtained and made intravenous inoculations into rabbits with results of which the following is an outline (Fig. 1).

FIG. 1.

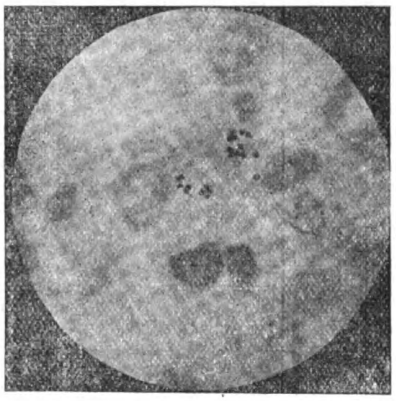


Micro-photograph of the diplococci from a culture upon blood-agar. The micro-organisms are arranged in small groups. The individual coccus is extremely minute, averaging 0·5 $\mu$. × 2100 times.

The pericardial fluid from Case 4, that of a boy who had died from an exacerbation of rheumatism, gave the first positive result. Three days after inoculation the animal limped upon the left fore leg, the left shoulder-joint was swollen, and the animal had lost flesh. Later the right hip-joint and right shoulder-joint became affected, wasting continued, and the rabbit died 10 days after inoculation. The post-mortem examination showed excess of clear fluid

in the right shoulder-joint and right hip-joint with reddening of the cartilages. The left shoulder-joint contained an opaque fluid which microscopically contained numerous endothelial cells and a few leucocytes. The heart appeared larger than natural, there was an excess of clear fluid in the pericardium, but apparently no evidence of pericarditis or endocarditis. The liver was dark red. In the lungs there were patches of broncho-pneumonia. There was no sign of abscess formation in any of the viscera. The clear fluid from the joints, taken with every precaution, was inoculated into milk tubes. Films were also made and a diplococcus was demonstrated and cultivated from this clear fluid. It was also demonstrated in the mitral valve (Fig. 2). Thus it will be seen that in

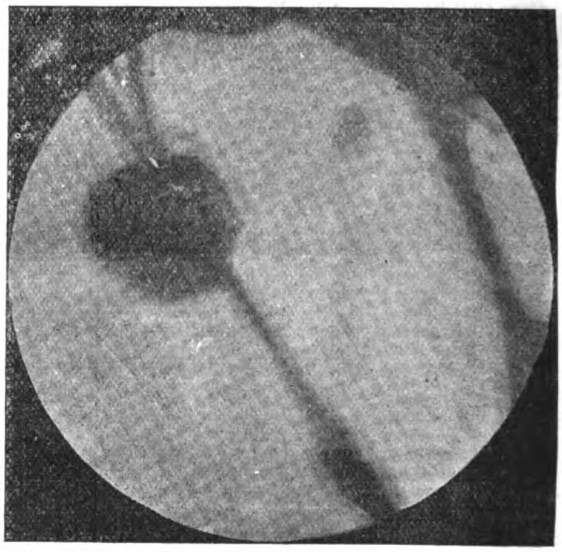
FIG. 2.



Micro-photograph showing the diplococci in the tissues. From a section through the mitral valve of a rabbit with early valvulitis. The valve showed the earliest evidences of a morbid change. The micro-organisms lay beneath the endocardium in the substance of the valve. The connective tissue cells of the valve had commenced to proliferate, giving rise to a slight projection upon the surface. The arrangement of the diplococci in small groups is somewhat characteristic. × 2100 times.

some respects our results in this case corresponded exactly with those of Wassermann. A polyarthritis had resulted and the joint first affected contained a fluid in which there were fibrin and some excess of leucocytes, the cartilages of the affected joints were redder than normal, and in none of the viscera were there any foci of suppuration. In one respect there was a difference and this was an important one: we had demonstrated the organism in the mitral valve. A second rabbit was inoculated from a culture of the joint fluid. The cultivations upon six blood agar tubes were injected intravenously into this rabbit with the following results. Upon the third day the right knee-joint swelled and the animal had lost 160 grammes in weight, then followed in succession the other knee-joint and the left shoulder-joint, and finally all the larger joints became implicated. The identity of the course of the disease with that in the first case was remarkable and certain further results developed. 17 days after the inoculation a systolic murmur was detected at the base of the heart somewhat superficial in character and the heart was acting with great rapidity. This murmur was detected for two days and then was lost and at the same time the heart sounds became faint. We diagnosed pericarditis with subsequent effusion. The next day the animal died. During the last week of the illness all the joint swellings had disappeared except that of the right knee. The necropsy showed an excess of clear fluid in the pericardium and a fibrinous coagulum in the sac with some roughening of the visceral layer over the large vessels. The right knee was full of an opaque fluid which, as in the first case, contained the diplococci, endothelial cells, and leucocytes. There was some excess of fluid in the other joints but this was clear. Upon the mitral valve there were two small white opacities resembling an early granulation. The liver was dark red and contained some small white areas which were quite firm and slightly raised. The spleen and kidneys were pale but otherwise natural. The tonsils were natural. Microscopic examination of the mitral valve did not confirm the suspicion of valvulitis. The opaque patches in the liver proved to be localised areas of coagulation necrosis. There was no trace of suppuration in the viscera. The myocardium showed well-marked fatty changes in the fibres comparable to the changes demonstrated by one of us (F. J. P.) in the human heart as occurring frequently in acute rheumatic carditis. The culture of the organism was repeated as before and the cultivations upon three tubes injected into a third rabbit, but with a negative result. The cultivations upon six tubes injected into a fourth rabbit resulted as follows. Four days after the inoculation the right knee-joint swelled and subsequently the right carpal joint and left knee-joint also and there was general wasting. Upon the tenth day we detected a soft murmur which next day we localised as mitral; this disappeared, but on the fourteenth day there was a murmur upon the right side which we diagnosed to be tricuspid in origin. The confirmation of these diagnoses being a matter of great importance upon the same day that the tricuspid murmur was detected the animal was killed. The necropsy showed that two joints contained an opaque fluid comparable to that found in the preceding cases and one a considerable quantity of clear fluid. There was excess of clear fluid in the pericardium (Fig. 3). The mitral valve showed

FIG. 3



Micro-photograph of a chorda tendinea, showing local swelling, the result of the diplococcus infection. A part of the mitral valve from a rabbit that had died from acute carditis was stained in bulk and stretched upon a slide together with its attached chordæ tendineæ. The upper limit of the photograph shows the lower margin of the valve. The chorda upon the left shows two swellings, an upper larger one close to the valve and a lower smaller one at its junction with the musculus papillaris. These swellings are caused by a connective tissue proliferation analogous to that in the valve substance and are the early expression of that change which in rheumatic fever results eventually in the deformity of the chorda tendinea seen in mitral stenosis.

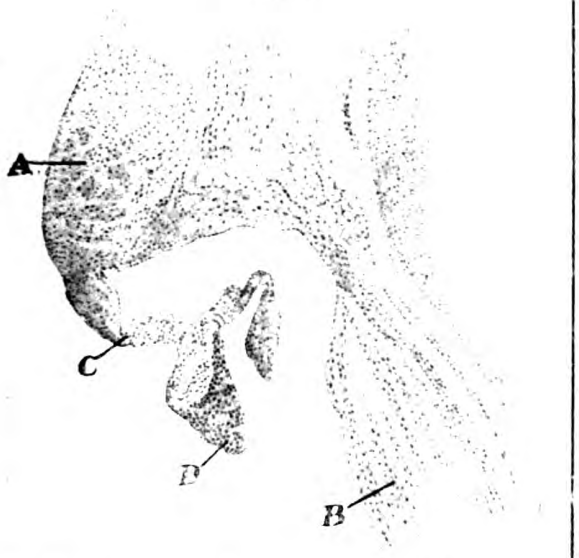
a condition macroscopically comparable to that of an early rheumatic valvulitis, and the tricuspid valve showed also, in the very earliest stage, a row of granulations along the border. The condition of the liver resembled that found in Case 2 and the kidneys also showed some white slightly raised areas quite firm on section. The tonsils were unaffected. The microscopic examination disclosed points of the greatest interest. In the parietal layer of the pericardium, stretched out and stained, we found the diplococci following the course of the blood-vessels in the perivascular lymphatic spaces. We also demonstrated them in the mitral valve and—what by the light of subsequent events was especially noteworthy—we discovered them in the kidneys in great numbers. There were no suppurative foci in the viscera (Figs. 4 and 5).

The organisms were once more isolated and injected intravenously into a rabbit. This rabbit developed polyarthritis, pericarditis, pleurisy, and pneumonia, with slight valvulitis.

The animal was killed at the height of the disease and the especial point of interest in the necropsy was the macroscopic appearance of the thoracic viscera. There were plastic pericarditis and mediastinitis, with plastic pleurisy over those parts of the lungs that are contiguous to the pericardium. The liver had the mottled appearance that is seen in man as a result of severe and acute rheumatic carditis. During the illness the rabbit had passed urine which was acid and contained numerous urates, granular casts, and diplococci. From the contents of the bladder we isolated and cultivated the diplococcus by the usual methods. There was also exudation into the tendon sheaths around the affected joints and the connective tissue near the larger joints had the gelatinous appearance of the nodule in man. We demonstrated the diplococci in the valves, pericardium, joint exudate, liver, kidneys, connective tissues around the joints, and in large numbers in the lungs and pleuræ. It is, we think, impossible not to recognise in this case the extraordinary similarity to the most severe types of rheumatic fever in childhood.

Another case in which some remarkable results occurred was the second of those in which we obtained a pure culture

FIG. 4.



THE MITRAL VALVE OF A RABBIT, TO SHOW THE COMMENCEMENT OF A VEGETATION (LOW POWER).

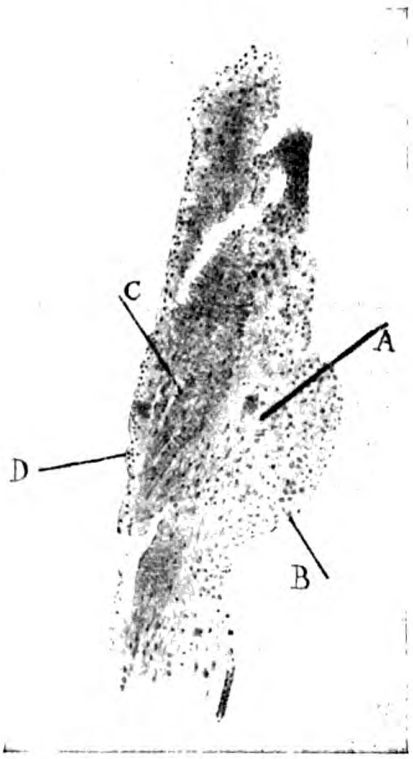
*A section through the auriculo-ventricular junction and mitral valve of a rabbit.*—In the process of embedding the valve has become somewhat bent upon itself, but it will be readily seen that the cellular proliferation (D) is upon the auricular surface. Under this magnification the organisms are not visible, but they are present at the margin of, and within, the cell proliferation.

*Explanation of the plate.*—A, The auricle. B, The ventricle. C, The mitral valve. D, The area of cell proliferation. Stain carbol-thionin.

of the diplococcus from the blood of a living patient suffering from rheumatic pericarditis. The organism was grown upon the acid medium and transferred to blood agar. Intravenous inoculation of a rabbit produced the following symptoms. Four days after inoculation the rabbit had begun to waste and limped upon the right hind leg, and the knee-joint became swollen. This continued for a week, the animal still wasting, but then it improved so much that the limp disappeared. The heart all this time acted very rapidly but there was no murmur. Five weeks after this there was a relapse and both the hind legs became very weak and the animal very emaciated. There did not appear to be any joint swelling at this time. This condition continued for about three weeks and then gradually passed off, and no cardiac murmur was detected at any time. Was this a paralytic phenomenon? It was a natural suggestion that it might be chorea, but, if so, there was not the slightest twitching, only this great weakness of both lower extremities that gradually passed away.

A third case which produced an experimental result was that of Case 6. The case was one of severe rheumatic carditis with early pericarditis. Associated with the diplococci there were some short bacilli and the growth in the pericardial fluid was accompanied by an offensive odour. An inoculation of the two organisms into a rabbit proved negative. An inoculation of the diplococci only into another rabbit also proved negative. We were surprised at this result and three weeks later a third attempt was made, though we felt very doubtful that any result would be obtained because of the difficulty of maintaining the virulence of the organism. This rabbit remained apparently well, but three weeks afterwards we found the temperature raised and a definite systolic murmur at the apex. There was no arthritic change, but the murmur remained constant for a week and was more definite than any that we had previously heard. The animal was then killed and the tricuspid and mitral valves were found to be

FIG. 5.



A transverse section of a cusp of the pulmonary valve, from a case of rheumatic carditis. The case, No. 7 in the series, was a characteristic example of rheumatic fever in childhood. After death the pericardium was found completely adherent and there were recent mitral aortic and pulmonary valvulitis. The pulmonary valve showed numerous minute projections upon the ventricular surface. The figure shows that the condition of the morbid change is still one of connective tissue cell proliferation and that the endocardium is intact. The diplococci were present in scanty numbers in the valve, but cannot be seen under this magnification. A, The commencing vegetation. B, The endocardium upon the ventricular surface. C, The connective tissue basis of the valve. D, The endocardium upon the arterial surface. Stain, carbol-thionin.

inflamed. There was also a moderate quantity of clear fluid in the abdominal cavity. We demonstrated the organisms in the valves and in the parietal pericardium, throughout which there was a definite cellular exudation.

The next case (Case 7) gave a negative result, but at this we were not surprised, for the pericardium was totally adherent, and though we obtained the diplococci from the granulations of the mitral valve they were in scanty numbers and the growth was not a vigorous one. No detectable clinical result followed the inoculation of a rabbit in the usual manner.

The last case (Case 8) was that of an adult, aged 32 years, who came to St. Mary's Hospital suffering from an acute

"sore throat." The throat was red and had the appearance of a rheumatic angina. There were muscular pains and a history of a previous attack of rheumatic fever. The heart was extensively diseased, both mitral and aortic valves were incompetent, and the action was excited and the præcordial dulness greatly increased in extent. The condition of the heart completely bore out the history of previous rheumatism. A culture was made from the throat in the milk medium and the diplococcus discovered among other organisms. This was isolated by means of blood agar plates and a pure culture injected intravenously into a rabbit. Three days after inoculation there was dyspnœa and the heart was acting with great rapidity. Two days after this a loud mitral murmur developed and the respirations were now extremely rapid. The rabbit died the same night somewhat unexpectedly. The necropsy showed great dilatation of the heart and a large vegetation upon the mitral valve with an adherent antemortem blood-clot filling the left auricle. We demonstrated the diplococci in the granulation, pericardium, and pleural exudation, and isolated them from the blood and cerebrospinal fluid.

It will be seen from this outline that on four different occasions very definite results have been obtained with rabbits. The results have been supported by demonstration of the diplococci both in the human and animal tissues. In addition to demonstrating the diplococci in the tissues in most of these eight cases we have found diplococci in the heart valves or pericardium in eight other examples of undoubted rheumatic fever, and in the pia mater and brain from a case of chorea with extremely violent movements, which proved fatal with but a slight valvular lesion and no pericarditis.

### THE OUTLINE OF THE METHODS OF BACTERIOLOGICAL INVESTIGATION.

1. *The materials for examination.*—The materials selected in the human subject for bacteriological examination were: (*a*) the pericardial exudation; (*b*) the blood from the heart; (*c*) the granulations from the valves; (*d*) the blood from the living subject during an attack of acute rheumatic pericarditis; and (*e*) the exudation from the inflamed tonsils. The material in the fatal cases was obtained as soon as possible after death and the necropsy was conducted with strict precautions for the prevention of contamination, all the instruments being carefully sterilised. The pericardium was exposed very completely by removing portions of the ribs as well as the costal cartilages upon the left side. The surface was seared with hot irons and any fluid present was drawn up in sterilised pipettes. The point of the pipette was broken off inside the pericardial cavity, the fluid withdrawn, and the pipette at once sealed. The surface of the right auricle was cauterised and the blood withdrawn in a similar manner. Finally, a sterilised suture was passed through the cardiac muscle at the apex and the heart pulled over to expose the left ventricle; then the posterior surface was thoroughly cauterised and rapidly opened with a sterilised knife, the walls were held apart by forceps, the blood-clot was removed, and the mitral valve was exposed and curetted.

2. *The culture media.*—Both liquid and solid media were used. The fluid media were incubated aerobically and anaerobically. The temperature of incubation was 37° C. The following media were used:—(*a*) Fluid.—(1) Bouillon and milk, acidified with lactic acid; (2) pork broth made with Chapoteaut's peptone and rendered strongly alkaline (in imitation of Wassermann's medium); (3) bouillon of various degrees of acidity and alkalinity; (4) ascitic fluid; and (5) cow's milk and human milk. (*b*) Solid media.—Agar, serum agar, blood agar, glucose agar, glycerine agar, and egg albumen. The organism grew best anaerobically in an acid medium. It also grew aerobically in the same medium and in blood smeared upon slightly alkaline agar. The anaerobic cultures were made in Pasteur's pipettes, which were exhausted by an air-pump and hermetically sealed. Films were invariably made from the culture used for experimental purposes before the inoculation.

The following is a detailed account of the eight cases of rheumatic fever with the investigations made from them.

CASE 1.—A girl, aged 17 years, was admitted into St. Mary's Hospital on Jan. 16th, 1899, suffering from purpura and rheumatic morbus cordis. This was the second attack of rheumatic fever and in addition five years before there had been an attack of chorea. This case was published in detail in THE LANCET of Oct. 28th, 1899, p. 1163. After a prolonged illness the patient succumbed to severe morbus cordis. A severe attack of pericarditis had developed while in the hospital and death occurred on April 15th. At the necropsy, which was made 24 hours after death, the pericardium was found to be adherent, the adhesions breaking down quite easily. The heart was enlarged and both hypertrophied and dilated. There was mitral, aortic, and tricuspid valvulitis. The other viscera showed the changes usually found in association with severe morbus cordis. There was one small infarct in the spleen. Under microscopical examination the cardiac muscle showed extreme fatty change. Bacteriology.—With Mr. H. G. Plimmer upon two occasions we made cultivations from the blood of the patient during life, taking advantage of a venesection that had been done for right heart-failure on each occasion. Both times we obtained from the tubes of the milk medium diplococci arranged in chains. The medium was treated aerobically and anaerobically. The milk tubes were the only media used.

*Note.*—At this time we were intent upon Achalme's researches and did not pursue the investigation of the cocci. In one of the anaerobic tubes we found a bacillus but were unable to isolate it, and after considerable investigation we came to the conclusion that it was a contamination.

CASE 2.—A patient, aged 19 years, was admitted into St. Mary's Hospital on Dec. 4th, 1899, suffering from pains in the joints and morbus cordis. This was the fourth attack of rheumatic fever. On admission there was advanced cardiac disease. Pericarditis rapidly developed and the patient died three days after admission. The necropsy, which was made 14 hours after death, showed recent pericarditis with turbid fluid in the pericardial sac, moderate stenosis of the mitral valve, and recent vegetations upon the aortic valve. Under microscopical examination the cardiac muscle showed much fatty change. Diplococci were demonstrated in the granulations of the mitral valve. Bacteriology.—The fluid from the pericardium was inoculated into the medium of milk acidified with lactic acid and aerobic and anaerobic cultures made. At this time we were still engaged in investigating Achalme's bacillus and following his directions the anaerobic tubes were left for 10 days. In both the aerobic and anaerobic tubes diplococci growing in a streptococcal arrangement were discovered. These organisms did not grow upon ordinary agar tubes. No inoculations were made into animals.

*Note.*—The strepto-diplococci were not thoroughly investigated, but it was found that an ordinary agar medium was not suited to them.

CASE 3.—A woman, aged 20 years, was admitted into St. Mary's Hospital, moribund, suffering from severe rheumatic pericarditis and mitral disease. The patient died the same day. The investigation was incomplete. Through a puncture in the pericardium we withdrew some sanious pericardial fluid in a sterilised pipette. Various media were used and from a bouillon tube and the milk medium we obtained diplococci contaminated with sarcinæ.

*Note.*—In this case the diplococci grew in chains in the acid milk medium in a manner precisely similar to that noted in the two preceding cases. Upon ordinary media these organisms failed to grow.

CASE 4.—A patient, aged nine years, was admitted into the Hospital for Sick Children, Great Ormond-street, on Oct. 11th, 1899, suffering from dropsy and morbus cordis. There was no definite history of rheumatism and no history of scarlet fever. Upon admission the heart was found to be enlarged and there was evidence of organic mitral disease. There were dropsy, albuminuria, and ascites. The illness was prolonged and the condition for some time stationary, but in March active rheumatism developed and nodules appeared; this was rapidly followed by cardiac failure and death on March 20th, 1900. At the necropsy, which was held 36 hours after death, the pericardium was found to contain some recent plastic exudation and excess of clear fluid. The valvular disease was slight but the heart was much dilated and hypertrophied. The lungs were œdematous, the liver was "nutmeg" in appearance, and the kidneys and spleen were firm. Under microscopical examination the cardiac muscle showed granular and fatty changes and films from the pericardial fluid and heart wall showed diplococci. Diplococci were also found in the mitral valve. Bacteriology.—(1) Three Pasteur pipettes of the pericardial fluid were incubated aerobically at 37° C. for three days; and (2) blood-agar tubes were inoculated with

the pericardial exudation and curetted granulations from the mitral and aortic valves. The diplococcus was found in every tube in pure culture. On blood agar they grew in discrete and easily detachable colonies. The pericardial fluid had increased in opacity and flakiness. The reaction of the pericardial fluid was distinctly acid and there was no offensive odour. Subcultures were made upon the milk medium, but on this occasion they did not grow well. Two tubes of the pericardial fluid were injected intravenously into a rabbit.

*Rabbit No. 1.*—Three days after the injection the animal was wasting and the left shoulder-joint was swollen. Nine days afterwards the right hip and shoulder had become swollen. On the tenth day from the date of inoculation the rabbit died from broncho-pneumonia. At the necropsy the heart appeared enlarged, but there was no definite valvulitis or pericarditis visible. There was a definite excess of clear fluid in the pericardial sac. The cartilages of the affected joints were reddened but there was no ulceration of their surfaces. The right shoulder-joint and right hip-joint contained an excess of clear fluid. The left shoulder-joint contained an opaque fluid and films afterwards showed that the fluid contained many endothelial cells from proliferation of the cells lining the synovial membrane of the joint together with a scanty number of leucocytes. The liver was dark red and engorged with blood. The spleen was firm and the kidneys were apparently natural. There were no traces of abscess formation anywhere. The lungs were solid in patches from broncho-pneumonia. There was no peritonitis. Under microscopical examination the strepto-diplococcus was demonstrated in the joint fluid and the mitral valve which was stained in bulk. The liver was engorged with blood. The heart showed no fatty change. The spleen and kidneys showed nothing distinctive. Bacteriology.—The clear fluid from the right shoulder joint and heart blood were used for inoculation of anaerobic tubes of the milk medium and 48 hours afterwards these tubes were found to contain the organism growing vigorously in chains. From these tubes six blood agar cultures were made aerobically. The six blood agar tubes were used for the inoculation of the second rabbit.

*Rabbit No. 2.*—Three days after inoculation the right knee-joint became stiff and the animal had lost 160 grammes in weight; four days afterwards the left shoulder became swollen; five days afterwards both the knee-joints became affected, and the right was more swollen; 14 days afterwards the animal was much wasted, the heart was rapid and feeble, and the animal was short of breath. The joints still remained swollen. 17 days after we detected a basal systolic murmur over the position of the large vessels; the next day this became fainter and then disappeared. With this disappearance the heart sounds became muffled at the base and we diagnosed as the most probable explanation a pericarditis with effusion. 20 days after inoculation the animal died. The swelling of all the joints except the right knee had gradually disappeared some days before death. At the necropsy the heart was enlarged and there was excess of clear fluid in the pericardium and also a viscid coagulum. The visceral layer of the pericardium showed slight roughening over the base of the heart. There was no definite valvulitis. The liver was dark red and mottled with white spots of varying size. The spleen was firm. The kidneys showed no definite changes. There was no trace of suppuration in any of the viscera. The affected joints were reddened and except in the case of the right knee contained a very slight excess of clear fluid. The right knee was distended with an opaque fluid which, as in the case of the first rabbit, contained many endothelial cells and also mononuclear and polynuclear leucocytes. The cartilages of the joints were unaffected. The tonsils were not inflamed. There was no peritonitis. Under microscopical examination: (1) in films from the joint the diplococcus was demonstrated in considerable numbers; (2) the heart muscle showed definite fatty change in many fibres; (3) the white patches in the liver proved to be liver cells undergoing necrosis; (4) the pericardial fluid clotted rapidly in the pipette after withdrawal, the clot in the pericardial sac and in the pipette showing a delicate fibrino-cellular structure; (5) the kidneys and spleen showed no change of note; and (6) there was no peritonitis. There were no foci of suppuration in the viscera. Bacteriology.—Cultures were made from the heart blood and right knee-joint in the milk medium and in both series of tubes the diplococcus was found growing vigorously in pure culture.

*Rabbit No. 3.*—A third rabbit was inoculated with the cultivations upon three blood agar tubes but with a negative result.

*Rabbit No. 4.*—A fourth rabbit was inoculated with the contents of six blood agar tubes and symptoms once more commenced to appear on the third day and developed as follows. On the third day after inoculation the right tarsal joint became swollen and tender. On the sixth day afterwards there was wasting and the left knee-joint was swollen. On the seventh day afterwards the right carpal joint swelled. The heart's action was excited and we suspected a mitral murmur. The next day this murmur was definite and then became less audible. On the tenth day after inoculation we suspected a tricuspid murmur and the animal was killed to verify these conclusions. For some days previously there had been very marked dyspnœa. At the necropsy the right carpal and tarsal joints were distended with an opaque fluid; the left knee-joint contained clear fluid. The cartilages were reddened but otherwise unaltered. The pericardium contained an excess of clear fluid. The heart was dilated. There was no visible pericardial roughening. The mitral valve showed definite granulations, the appearance exactly resembling an early rheumatic endocarditis. The tricuspid valve showed a still earlier stage. The aortic and pulmonary valves were unaffected. The liver was dark red and mottled with firm white areas, some of them slightly raised above the surface. The spleen was pale but firm. The kidneys were both pale and contained a few white areas, firm and slightly raised above the surface. The tonsils were unaffected. In none of the viscera were there any foci of suppuration. There was no peritonitis. Under microscopical examination (1) in the parietal layer of the pericardium, stretched out and stained in bulk, the diplococci were clearly seen in great numbers along the course of the vessels, lying apparently in the perivascular lymphatic spaces; (2) the mitral valve showed on section an early granulation on the auricular surface, consisting of a proliferation of the connective tissue cells of that part of the valve. The delicate endothelial layer of the endocardium passed over this granulation, and in the granulation and in the deeper part of the endocardium diplococci were visible. They could be seen also in the endocardium lining the auricle and ventricle and causing in places cell proliferation. They were also present in considerable numbers in the retiform tissue at the base of the valve, that is, in the position of the valve ring; (3) the joint fluid showed numerous diplococci and endothelial cells, also eosinophiles and some polynuclear leucocytes; (4) the liver showed numerous areas of coagulation necrosis; (5) the kidneys showed areas of coagulation necrosis, especially in the region of the convoluted tubules and numerous diplococci in these areas; (6) the heart muscle showed well-marked fatty and other degenerative changes; and (7) there was no peritonitis. Bacteriology.—The diplococci were obtained in pure culture from the joints and heart blood. This case made clear several important facts: (1) the early and definite affection of the heart which we had suspected previously to be a result of the infection became now a certainty; (2) the post-mortem appearances of the heart and the microscopic changes were analogous to those found in rheumatic fever; (3) again there was no suppuration in the viscera; and (4) the kidneys showed that the diplococci were present in great numbers. Inoculations were next made from the cultivations upon six blood agar tubes obtained from the foregoing case and were injected into a rabbit in the usual way.

*Rabbit No. 5.*—The rabbit developed the following symptoms. Four days after the inoculations the right carpal joint was swollen and the heart was rapid and excited. Other joint swellings followed. The cardiac rhythm became triple and later the action irregular. There were marked dyspnœa and a mitral murmur. Seven days after we heard a pericardial friction sound and diagnosed also pneumonia over the fronts of both lungs. Upon the previous day a great quantity of thick white urine was passed. On the eighth day the rabbit was killed, with the diagnosis of pericarditis, valvulitis, pneumonia, and polyarthritis. At the necropsy the appearance of the thoracic organs was such as is seen in severe rheumatic fever. There were pleurisy with plastic exudation and pneumonia over those parts of the lung that covered the heart. There were also mediastinitis and recent plastic pericarditis with some effusion of clear fluid in the pericardial sac. The heart was greatly dilated and the muscle was pale. The mitral valve showed early valvulitis. The liver was enlarged and mottled red

and white, just such an appearance as is seen in acute rheumatism. There were no white firm areas as in former cases. The spleen was enlarged and was softer than in previous cases. Both kidneys were pale. The joints contained an opalescent fluid and the connective tissue around them had the gelatinous appearance suggestive of a nodule formation. The tendon sheaths around the right tarsal joints contained an opaque fluid. There was no peritonitis. The tonsils were not affected. The bladder was much distended and thick white urine was withdrawn by a pipette. This fluid on adding acetic acid cleared rapidly. The urine under the microscope showed numerous dumb-bell shaped crystals of uric acid, diplococci, and granular casts. There was no suppuration in the viscera. The heart muscle was at once teased and examined microscopically. Numerous clear granules were seen in the fibres, which stained faintly with osmic acid. Under microscopical examination the diplococci were demonstrated in the mitral and tricuspid valves and in the pericardium; also in the joints, connective tissue around the joints, kidneys, and liver. In the lungs and pleuræ they were present in very great numbers, especially towards the surface. Bacteriology.—The inoculations were made in the usual way and a free growth obtained upon blood agar. The organisms were in this case isolated from the bladder.

*Note.*—This case presented the most striking resemblance to severe rheumatic fever both clinically and in the pathological results. The condition of the thoracic viscera was just as is seen in the virulent pleuro-pericarditis of rheumatic fever in childhood. The diplococci in this case were demonstrated in the lungs and liver.

CASE 5.—A youth, aged 16 years, was admitted into St. Mary's Hospital on March 20th, 1900, suffering from rheumatic pericarditis. This was the second attack of rheumatic fever and in addition he had suffered from chorea at the age of 15 years. The illness had commenced a fortnight previously to admission with a sore throat and pain in the right knee, followed by shivering, and pain in the chest. On admission there were general pericardial friction and mitral, and a suspicion of aortic, valvulitis. The heart was much dilated and right heart failure was threatened. On this account he was venesected. This patient made an excellent recovery from the pericarditis, but left the hospital in May with evidence of organic valvular disease. Bacteriology.—On March 24th the patient was venesected and due precautions were taken to obtain the blood free from contamination. Three different media were used: (1) the milk medium (acid); (2) the pork medium (strongly alkaline); and (3) the bouillon medium (alkaline). Anaerobic tubes were made of these media. In one anaerobic milk-tube the strepto-diplococci were growing vigorously. The remaining tubes were sterile. From the anaerobic milk-tube sub-cultures were made and a blood agar tube was inoculated upon which discrete colonies of the diplococci made their appearance. Sub-cultures were made and the remainder injected intravenously into a rabbit.

*Rabbit No. 6.*—Four days after inoculation the rabbit limped, the right knee-joint was swollen, and it had lost flesh. 11 days afterwards it was still limping and was thinner. 21 days afterwards, though the heart was very rapid, the limp had disappeared and a slight improvement set in. Five weeks afterwards there was a relapse and both hind legs became affected, and the animal could not support the weight upon them. It was now very thin. The heart sounds were very feeble and rapid but there was no murmur. This affection of the hind limbs seemed to be a paralytic phenomenon and no swelling of the joints was apparent. There was no twitching. This symptom also passed away in about three weeks and the animal could use both hind legs again in a normal manner.

CASE 6.—A girl, aged thirteen and a half years, was admitted into St. Mary's Hospital on March 25th, 1900, suffering from active rheumatism and morbus cordis. In January, 1900, the first attack of rheumatism occurred. The present illness had lasted three weeks. On admission the child was very ill. There were numerous nodules, the heart was dilated, there was organic mitral disease, and there was general pericarditis. She grew rapidly worse and died on the 30th. The necropsy, which was made eight hours after death, showed recent lymph upon the visceral pericardium and turbid fluid in the sac. There were recent granulations upon the mitral valve and some thickening of the cusps of the aortic valve. The liver showed an early nutmeg change. The spleen was firm and dark. The kidneys were pale. The pericardial fluid was definitely acid in reaction. On microscopical examination the heart showed very marked fatty change in the muscle fibres and diplococci were demonstrated in the granulations of the mitral valve. Bacteriology.—Films made of the pericardial fluid after incubation showed diplococci and a short bacillus. A cusp of an aortic valve and a piece of the mitral valve were stained and examined in bulk but no organisms were found. A section of the mitral valve showed the cocci in the granulations. The following cultures were made: (*a*) the pericardial fluid was incubated in pipettes; (*b*) the lymph was introduced into (1) blood agar, (2) the milk medium (acid), and (3) the pork medium (alkaline); and (*c*) fragments curetted from the mitral granulations were also placed in the same media. The heart blood was also introduced into other tubes of the same media. Anaerobic tubes were made of the milk medium (acid). The results were as follows. Two of the pipettes of pericardial fluid were sterile, one contained the diplococci, but with them numerous small bacilli, and the odour of the fluid was offensive. The blood agar was sterile. The tube of the heart blood was sterile. A blood agar tube was made from the pericardial fluid. The following inoculations into animals were made. 1. Five minims of the pericardial fluid containing the diplococci and bacilli were injected intravenously but the result was negative. 2. Later the contents of six blood agar tubes from a sub-culture were inoculated but the result was again negative. Later a third attempt was made. The culture upon blood agar was growing, but not vigorously, and a sub-culture was accordingly made in the acid medium and then this re-transferred to six blood agar tubes.

*Rabbit No. 7.*—A rabbit was inoculated but no apparent result followed until three weeks after the inoculation, when a definite systolic murmur was detected at the apex and the temperature in the rectum was found to be 102·8° F. No joint lesion developed and after detecting the murmur each day for a week the animal was killed. The necropsy showed definite tricuspid and mitral valvulitis and a definite excess of clear fluid in the peritoneal cavity. The organism was demonstrated in the valves and parietal pericardium in which there was definite cellular exudation.

*Note.*—This case corresponded clinically to the well-known rheumatic condition of organic valvular disease occurring without arthritis.

The pyrexia in the rabbits in these cases was moderate, the range being from 101° to 103·4° F. The temperature was taken in the rectum. In the more severe cases the fever was continuous though with some oscillation.

CASE 7.—A boy, aged nine years, was admitted into the Hospital for Sick Children, Great Ormond-street, on Feb. 26th, 1900, suffering from rheumatic fever from which his mother also had suffered. On admission there were pericarditis and arthritis. The illness was prolonged and after a partial improvement a relapse of carditis occurred and terminated fatally on April 30th. At the necropsy, which was made 30 hours after death, the tonsils were found to be large and inflamed. There was consolidation of areas of both lungs. The heart was large and the muscle pale and soft. The pericardium was generally adherent, the adhesions breaking down easily. There were recent granulations upon the mitral and aortic valves and the pulmonary valve showed very early inflammation. The liver, kidneys, and spleen showed the usual changes. At the microscopical examination the important fact was the demonstration of the diplococci in the tissue of a rheumatic nodule. The nodule was of about the size of a small pea and was situated over the left olecranon. The diplococci were in small clumps in the fibrous tissue. We are not aware that they have been demonstrated before in these structures which are looked upon as extremely characteristic of rheumatic fever. Bacteriology.—The recent granulations on the mitral and aortic valves were curetted and the heart blood taken in a sterilised pipette. Films from the mitral granulations showed a few diplococci. The milk medium and blood agar tubes were used. The milk medium was treated anaerobically, and from the curetted granulations of the mitral valve a growth of strepto-diplococcus was obtained but it was not abundant. The usual blood agar tubes were made but the growth was poor. Intravenous inoculation in a rabbit (No. 8) proved negative.

CASE 8.—A man, aged 28 years, came into St. Mary's Hospital on June 7th, 1900, suffering from a "sore throat." The illness had commenced with general malaise and pains in the

limbs and joints. There was a history of a definite attack of rheumatic fever four years before. The throat was injected and the tonsils were in a condition of acute catarrh. The heart was much enlarged and both mitral and aortic valves were incompetent. The enlargement of the heart, the character of the murmurs, and the pulse all pointed to a previous attack of rheumatic carditis and confirmed the history of previous rheumatism. We diagnosed from the history, the appearance of the throat, and the excited action of the heart that the condition was one of rheumatic tonsillitis. A culture was made upon the acid milk medium and the tube incubated aerobically. Minute diplococci were found in a film in association with other micro-organisms. Bacteriology.—24 hours after the culture had been made a film showed that a diplococcus was growing in association with other micro-organisms and blood agar tubes were inoculated from the milk culture. On the 12th blood agar plates were made from these tubes and a diplococcus isolated and transferred to blood agar tubes. The diplococcus resembled morphologically and in its growth that found in the seven preceding cases. On the 14th the contents of six blood agar tubes were injected intravenously into a rabbit.

*Rabbit No. 9.*—On June 15th the respirations were rapid and the action of the heart was excited. On June 16th the heart sounds were loud and the action was very rapid. On June 18th there was suspicion of a systolic apical murmur and of pleurisy. On June 19th a very loud systolic apical murmur was discovered and both pleurisy and pericarditis were suspected. The rabbit died in the night somewhat unexpectedly. At the necropsy the heart was found to be greatly dilated and there was some excess of fluid in the pericardial sac. The mitral valve showed a large vegetation upon the anterior flap and to this a large ante-mortem clot occupying much of the left auricle was firmly adherent. The posterior flap was reddened. The aortic valves were reddened and the aorta close to the valve showed a small patch of aortitis. The tricuspid valve was reddened. The pulmonary valve was apparently normal. There was recent fibrinous exudation in the pleuræ. The lungs were engorged and solid in small areas, close beneath the pleuræ. There was no trace of suppuration in any of the viscera. Under microscopical examination the diplococci were demonstrated in the vegetation of the mitral valve, in the pericardium, and pleural exudation. Bacteriology.—Cultivations were made anaerobically in the acid medium from (*a*) the blood and (*b*) the cerebro-spinal fluid from the lateral ventricles. In both instances the diplococci were obtained in pure culture.

*Note.*—This case by the light of the former one is of extreme interest. 1. It demonstrated conclusively that these diplococci when present in the throat of a man the subject of rheumatic fever will, if isolated during an attack of angina faucium, cause valvulitis and pericarditis, both non-suppurative, when inoculated intravenously into a rabbit. 2. The presence of the micro-organism in the cerebro-spinal fluid is very suggestive when the close association of chorea and rheumatic fever is considered from this point of view.

*(To be continued.)*

## SOME POINTS ABOUT POST-DIPHTHERITIC PARALYSES.

BY BERNARD E. MYERS, M.D.[EDIN., L.R.C.P. LOND.

FOR being able to publish the following details concerning post-diphtheritic paralyses I have to thank Dr. R. A. Birdwood of the Park Hospital, Hither Green, through whose courtesy I was permitted to have free access to the case-books, wards, and laboratories of the above hospital. I hope that the facts herein contained will be found lucid and concise. The figures are based upon all the cases of diphtheria admitted into the Park Hospital during 1899, and I start first with general facts and then enter upon a few points of special interest.

Without further comment I will start with the general facts for the year 1899, which were as follows. During 1899 there were 1316 cases of diphtheria in the wards. In the one year there were 275 cases of post-diphtheritic paralysis or paresis, so that in about one case of diphtheria out of every five cases the patients suffered from paralysis or paresis. There were 147 cases in males and 128 in females. Considering that the number of males and females admitted with diphtheria in 1899 were almost exactly the same, the above shows that the males (53·5 per cent.) suffered more from paralysis after diphtheria than the females (46·5 per cent.). Of those who suffered from paralysis there were 80 deaths (29 per cent.), 44 occurring in males (55 per cent.) and 36 in females (45 per cent.).

TABLE I.—*Incidence of Paralysis and Paresis in Age-periods and Sex for the Year 1899.*

| Ages. | Males. | Females. | Total. |
|---|---|---|---|
| Under 1 year | 2 | 3 | 5 |
| 1 to 2 years | 7 | 9 | 16 |
| 2 „ 3 „ | 9 | 8 | 17 |
| 3 „ 4 „ | 22 | 15 | 37 |
| 4 „ 5 „ | 19 | 10 | 29 |
| 5 „ 6 „ | 15 | 25 | 40 |
| 6 „ 7 „ | 19 | 16 | 35 |
| 7 „ 8 „ | 17 | 16 | 33 |
| 8 „ 9 „ | 7 | 9 | 16 |
| 9 „ 10 „ | 8 | 6 | 14 |
| 10 „ 11 „ | 8 | 4 | 12 |
| 11 „ 12 „ | 3 | 2 | 5 |
| Over 12 „* | 11 | 5 | 16 |
| Totals... ... | 147 | 128 | 275 |

* Including those in their thirteenth year. The ages of these patients were as follows: two were 12 years of age, four were 13 years, four were 14 years, three were 15 years, one was 16 years, one was 20 years, and one was 35 years.

TABLE II. *The 275 Cases taken in Five-yearly Periods.*

| Age-periods. | Males. | Females. | Total. |
|---|---|---|---|
| Under 5 years.* | 59 | 45 | 104 |
| 5 to 10 years.* | 66 | 72 | 138 |
| Over 10 years. | 22 | 11 | 33 |
| Totals... ... | 147 | 128 | 275 |

* In the age-period from three to eight years the numbers were: males, 92; females, 82; total, 174.

Thus out of 275 cases of paralysis and paresis for all ages we find that there were 174 cases that occurred between the ages of three and eight years, equalling 63·2 per cent. of the total number. Again, we see that there were 40 cases between the fifth and sixth year of age, equalling 14·5 per cent. of the fatal cases for all ages, which in the above table is in excess of any other period of life. The females suffered most severely in the five to six years period, whilst the males fared worst in the three to four years period, but this latter does not prove such to be the case absolutely without stating the number of each sex admitted from three to four years of age and from five to six years of age respectively.

### CARDIAC PARALYSIS.

By cardiac paralysis, or as it has sometimes been called "vagus paralysis," I mean to infer those cases which are clinically characterised by (1) heart failure, (2) vomiting, (3) blueness of the skin and the mucous membranes, and (4) generally coldness of the extremities in the final stages. As regards the circulatory system the following conditions are met with, those first mentioned being the most common ones: dilated heart; weak action of the heart; irregular, intermittent, or tachycardiac heart; the heart sounds are approximated; the first sound is faint, short, with systolic murmur, or is heard reduplicated at the mitral and the tricuspid areas; the galloping rhythmic heart; the brady-cardiac heart; and the heart with pulmonary systolic murmur. Generally several of the above conditions are associated together. Thus it is very frequent to find in the heart in a cardiac case at some period dilatation, weak action, irregularity, intermittency, tachycardia, approximation of the first and second sounds, and a short faint first sound often with a systolic murmur. When galloping rhythm is observed it is generally near the end. The pulse is generally very

fast, it is frequently irregular, is often hardly felt (especially when death is approaching), and frequently it is intermittent. As a rule all the above conditions are noticed in cardiac cases in some stage or other. There are occasionally hæmorrhages in these cardiac cases. They may be subcutaneous and are generally small in extent or there is sometimes epistaxis, &c. In some cases there is collapse and very sudden death. The temperature is first 2° or 3° up and then subnormal. In the respiratory system breathing may be laboured and there is occasionally sighing respiratory action. Œdema of the lungs is not infrequent. With regard to the urinary system albuminuria is almost invariably present; not infrequently there is suppression of the urine, and occasionally there is hæmaturia. The general nervous symptoms are: convulsions, drowsinesss, delirium (occasionally), and restlessness (frequently).

The above-mentioned facts enumerate the chief symptoms and signs in cases of cardiac paralysis, though of course there are others, but these perhaps are the ones worthy of mention. Some of the facts, especially those relating to the urinary system, are also what one might get in a case of diphtheria without the paralysis.

During the year there were 30 deaths in the various forms of paralysis after diphtheria and 64 of these cases were due to cardiac paralysis, so that only 16 deaths were due to other causes, whilst 80 per cent. of the deaths were the result of cardiac paralysis. Of all forms of paralysis 23 per cent. were of the cardiac variety, and of the 64 cases of cardiac paralysis 33 were in males and 31 in females.

TABLE III.—*Season in Cardiac Paralysis and the Approximate Proportion of Cardiac Cases to the Total Number of Diphtheritic Cases Admitted Each Month.*

| — | January. | February. | March. | April. | May. | June. | July. | August. | September. | October. | November. | December. |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Number of patients admitted with diphtheria in various months... ... | 71 | 113 | 67 | 48 | 73 | 113 | 148 | 115 | 111 | 158 | 159 | 135 |
| Number of cases in each month ... ... | 5 | 6 | 4 | 2 | 3 | 1 | 9 | 4 | 4 | 11 | 10 | 5 |
| Approximate proportion of cardiac cases | 1 to 14 | 1 to 19 | 1 to 17 | 1 to 24 | 1 to 26 | 1 to 113 | 1 to 16 | 1 to 29 | 1 to 28 | 1 to 14 | 1 to 16 | 1 to 27 |

*Age-periods of cardiac paralysis.*—Under the age of one year there was one case, from one to two years there were four cases, from two to three years 10 cases, from three to four years seven cases, from four to five years seven cases, from five to six years six cases, from six to seven years 12 cases, from seven to eight years six cases, from eight to nine years six cases, from nine to 10 years there was one case, from 10 to 11 years there were two cases, and from 13 to 14 years two cases. Here we find the great proportion of cases occurring between the ages of two and nine years inclusively, the majority being in the six to seven years age-period. After nine years of age there is a great falling off in these cases.

*The number of days after the beginning of an attack of diphtheria that the symptoms and signs of cardiac paralysis were first noted.*—In one instance the symptoms came on upon the second day of illness, while in one other case it seems to have been on the thirty-sixth day. These marked the two extremes. Of the 64 cases the average date upon which the symptoms appeared was the seventh day.

*Duration of cardiac paralysis.*—The extremes were one day and 14 days, though, perhaps, some doubt may be expressed as to the latter period. The average duration of life after cardiac paralysis was first clinically noted was four days.

*The temperature in cardiac paralysis.*—A fact which strikes one forcibly after looking over some 100 odd charts is that there seems to be one particular kind of chart which occurs in most cases of cardiac paralysis, especially seen in those cases which run their course in from six to nine days. For instance, a patient, aged six years, came in on the fourth day of the disease with a temperature of nearly 101°F., which fell to 100° on the fifth day, then on the sixth day there was a drop to 97°, and though the temperature nearly rose to normal again for a short time it kept near the 97° till the ninth day of illness, when it was below 97° and death occurred. The cardiac symptoms in this case came on upon the sixth day of the disease.

*Greatly swollen cervical glands in the early stages of cardiac paralysis.*—Large numbers of these cases show early great swelling of the cervical glands, generally bilateral. It certainly does not occur in all cases for there is a fair proportion without and, indeed, many cases show only the slightest enlargement. Still, cases of diphtheria with greatly enlarged cervical glands in the early stages require urgent attention and frequently turn out to be cardiac cases. The amount of membrane seen in these cases is not of much diagnostic importance, for though cardiac cases often have much membrane there is just as frequently very little, and again we often see many cases which are non-cardiac with great masses of membrane.

## DIAPHRAGMATIC PARESIS AND PARALYSIS.

There were 21 cases of this form of paralysis during the year, which compared with the total cases of all forms of paralysis and paresis during the same period, 275, gives the result that 7·6 per cent. of cases were diaphragmatic. It may be here mentioned that as diaphragmatic paralysis rarely occurs without some other paralysis or paresis these cases, with only one or two exceptions, contained various other parts affected in the same patient, as will be seen directly.

*Deaths from diaphragmatic paralysis.*—Of 21 cases of the above paralysis 11 terminated fatally and in 10 the patients recovered, so that practically half of the patients succumbed, and compared to the total deaths for the year from all forms of paralysis we find that 13·7 per cent. were due to diaphragmatic paralysis. In the 21 cases 13 were males and eight were females. The age distribution in these cases was as follows. Under the age of one year there were no cases, from one to two years there were two cases, from two to three years three cases, from three to four years six cases, from four to five years two cases, from five to six years five cases, from six to seven years no cases, from seven to eight years there was one case, from eight to nine years one case, from nine to 10 years there were no cases, and from 10 to 11 years there was one case. Most of the cases occurred between the ages of two and six years. As to the day of disease upon which diaphragmatic signs were first noticed clinically the two extremes were 11 and 50 days respectively, while the average time was 37 days. The duration of fatal cases after paralysis first set in was three days for the minimum time, while one case was put down at 65 days; but this case is not counted in the average, as when the first signs were noticed they were doubtful and probably the diaphragm did not suffer till some little time later. The average duration was from six to seven days.

The following are brief particulars of the various forms of paralysis or paresis which were associated with diaphragmatic paralysis and the day of onset in each case, counting from the initial symptoms of diphtheria to the first time the paralysis, &c., was noted.

*The palate and the diaphragm.*—Case 1.—The patient was a male, aged four years. The palate, 50 days; and the diaphragm, 50 days. Case 2.—A female, aged three years. The palate, 24 days; and the diaphragm, 27 days. Case 3.—A male, aged five years. The palate, 11 days; and the diaphragm, 11 days. Case 4.—A male, aged three and a half years. The palate, 35 days; and the diaphragm, 46 days. The point of interest is that the palate was always affected either before or at the same time as the diaphragm.

*The palate, the internal rectus, the muscles of deglutition, and the diaphragm.*—Case 1.—A male, aged three years. The palate, 31 days; the muscles of deglutition, 32 days the internal rectus, 33 days; and the diaphragm, 36 days. Case 2.—A male, aged one and a half years. The palate, 25 days; the muscles of deglutition, 37 days; the internal rectus, 41 days; and the diaphragm, 61 days. It will be noticed that the same order was maintained in each case.

*The palate, ocular, and the diaphragm.*—Case 1.—A female, aged four years. The palate, 20 days; ocular, 20 days; and the diaphragm, 39 days. Case 2.—A male, aged one and a half years. The palate, 22 days; ocular, 48 days, and the diabpragm, 46 days. Here the palate was amongst

the first to suffer, but the ocular affection varied. The above are returned as "ocular" because the particular muscles of the eye are not stated.

*The larynx, the palate, the external rectus, and the diaphragm.*—Case 1.—A female, aged five years. The external rectus, 31 days; the palate, 36 days; the larynx, 37 days, and the diaphragm, 40 days.

*The muscles of deglutition, the internal rectus, the ciliary muscle, and the diaphragm.*—Case 1.—A male, aged two and a half years. The muscles of deglutition, 29 days; the diaphragm, 34 days; the right internal rectus, 35 days; and the ciliary, 36 days.

*The right external rectus, the flexors of the neck, and the diaphragm.*—Case 1.—The diaphragm on the thirty-eighth day.

*The palate, the external rectus, and the diaphragm.*—Case 1.—A male, aged seven years. The palate, 20 days; the external rectus, 17 days; the diaphragm, 43 days. Case 2.—A male, aged five years. The palate, 24 days; the external rectus, 39 days; and the diaphragm, 47 days. Case 3.—The palate, 29 days; the external rectus, 45 days; and the diaphragm, 39 days. The variable position of the external rectus is seen, though the palate generally suffered first and the diaphragm generally last.

### PARESIS AND PARALYSIS OF THE PALATE.

There were 110 cases where the palate alone was affected, which equalled 40 per cent. of the total number of cases of various kinds of paralysis and paresis for the year. With regard to sex there were 61 cases in males and 49 in females. The minimum age was one and a half years, the maximum 35 years, whilst the average age was seven years. As to the day of onset the minimum time was the eighth day of diphtheria, the maximum the fifty-fifth day, and the average the twenty-seventh day. The following list shows fairly well how often the palate is affected either alone or with other parts:—

| | | |
|---|---|---|
| The palate alone | ... ... ... ... ... | 110 cases. |
| ,, with the ciliary muscles | ... | 5 ,, |
| ,, ,, external rectus | ... | 27 ,, |
| ,, ,, ocular muscles | ... | 3 ,, |
| ,, ,, right facial | ... ... | 1 case. |
| ,, ,, ciliary muscles and pupils | ... ... ... | 2 cases. |
| ,, ,, larynx | ... ... ... | 1 case. |
| ,, ,, diaphragm | ... ... | 17 cases. |
| Total of times palate suffered | ... ... ... | 166 cases. |

So that of 275 patients suffering from paralysis, &c., in 166 of these patients the palate was affected either alone or with others parts, which equals 60 per cent. of all the cases.

TABLE IV.—*Distribution of Paralysis and Paresis in the Various Months.*

| Month. | Cardiac. | Diaphragmatic. | All other forms. | Number of patients admitted to hospital. |
|---|---|---|---|---|
| January ... ... ... ... | 5 | 2 | 16 | 71 |
| February ... ... ... ... | 6 | 1 | 15 | 113 |
| March ... ... ... ... | 4 | 1 | 16 | 67 |
| April... ... ... ... ... | 2 | 2 | 13 | 48 |
| May ... ... ... ... ... | 3 | 0 | 17 | 78 |
| June ... ... ... ... ... | 1 | 0 | 10 | 113 |
| July ... ... ... ... ... | 9 | 3 | 18 | 148 |
| August ... ... ... ... | 4 | 3 | 33 | 115 |
| September ... ... ... | 4 | 4 | 22 | 111 |
| October ... ... ... ... | 11 | 1 | 7 | 158 |
| November ... ... ... | 10 | 1 | 11 | 159 |
| December... ... ... ... | 5 | 3 | 12 | 135 |
| | 64 | 21 | 190 | 1316 |
| | | 275 | | |

The cardiac and diaphragmatic cases have been discussed before. Under the heading "All other forms" every kind of paralysis and paresis barring the above two are included, but the majority of the cases in this list were those of palate paresis. The number of cases of paralysis can be compared in each month with the number of patients admitted with diphtheria. Noticeable points under the heading "All other forms" are the great number of cases in August (33) and the comparatively small number in October (seven); and it will be seen on looking at the table that just the opposite conditions obtain in cardiac paralysis, where there were rather few cases in August (four) and the greatest number in October (11.) November is somewhat similar to October.

Goldhurst-terrace, West Hampstead.

SOME NOTES ON THE

## USE OF MERCUROL: A NEW REMEDY IN URETHRITIS.

BY RAMON GUITERAS, M.D.,

PROFESSOR OF GENITO-URINARY SURGERY IN THE POST-GRADUATE MEDICAL COLLEGE OF NEW YORK; LECTURER ON GENITO-URINARY SURGERY IN THE UNIVERSITY OF THE CITY OF NEW YORK, ETC.

DURING the last few years several so-called specifics for the treatment of urethritis have been placed on the market, the most prominent of which have been "argonin" and "protargol," both silver derivatives. Argonin, I believe, has lost its popularity somewhat on account of the difficulty some find in preparing a solution from it, and also on account of its liability to decompose. These difficulties were not considered against it until protargol was placed upon the market, which many think to be a superior preparation. Both of these compounds have been used by me in my private practice and clinics with good results.

Some months ago a new remedy was introduced, called "mercurol," which has been given a thorough trial in my clinic, and from the clinic history book of the cases treated by this remedy I have drawn certain conclusions which I present in this paper. Let us first consider what mercurol is before treating of its clinical results.

Mercurol is a chemical compound of nucleinic acid with mercury, the nucleinic acid being obtained from yeast. This organic combination, in the form of a brownish-white powder, is soluble in water but insoluble in alcohol. It does not precipitate albuminous liquids and is not precipitated by alkalies. All that the manufacturers claim for mercurol is that the action of the mercury is rendered more effective and less irritating than it would be outside of this combination. It is not claimed that the nucleinic acid exerts any remedial action, but only that it facilitates the action of the mercury. Briefly, the effect claimed for the nucleinic acid admixture is to render it possible to administer mercury in much larger doses than otherwise would be possible and that without pain or disagreeable symptoms to the patient.

During four months this remedy has been used quite extensively in my clinic at the Post-Graduate Medical School, and 150 cases in all have been treated by this drug, although the statistics that I quote have been taken only from patients who have come in during the last three months before writing this paper. The reason of this is because during the first month in which it was used we did not know what was the preferable strength to prescribe and also because it is our custom in introducing any new remedy to begin with what we consider the minimum strength. In using mercurol we began with a quarter of 1 per cent. and gradually increased it to, in some cases, as high as 5 per cent. By this means it was found that whereas the solutions of smaller percentage had little more effect than water, the stronger solutions were so irritating that the patients usually complained of them at first. We therefore concluded that the average strength that could be best borne by the patient was 10 grains to the ounce, or approximately 2 per cent. Since arriving at this conclusion we have had 100 cases on our books the records of which have been carefully kept. It cannot be said positively that all these cases are true cases of gonorrhœa, as only 33 of them were examined for the gonococcus, and of this number in only 30 was it found to be present. In the remaining 67 no bacteriological examination was made, or, if so, no mention was made of it, and the diagnosis was a clinical one. It is probable, however, that nearly all of these cases were cases of the disease in question, as the experienced eye is usually able to distinguish it. One of the above cases was extremely interesting

as no gonococcus could be found in the urethral discharge, although gonococci were present in that of some venereal ulcers situated on the glans. In prescribing the mercurol solution in these cases a 2 per cent. solution was ordered and the patients were directed to inject themselves with it by means of a small urethral syringe after urinating three times a day and to hold in the injection each time for five minutes.

How mercurol acts is still a question. As it is a germicide we would expect it to kill the gonococcus, but we do not as yet know the action of all germicides. It was supposed for a long time that urethral irrigations of a permanganate of potassium solution cured the disease by killing the gonococcus, but investigations later showed that this was not the case, but that they gave rise to a sub-mucous œdema which was an unfavourable culture ground for the bacteria and they ceased to multiply. The clinical reports of our cases, however, show that frequently in two days after beginning the use of mercurol the gonococci could no longer be found in the discharge, while in some cases they continued to be present for more than a month. In other cases the gonococci disappeared in a few days and then returned and continued in the discharge for some time longer, until shortly before it had ceased, or else the patient left the clinic and consequently could not be kept under observation. In one of the cases reported, for instance, the gonococcus disappeared in five days and returned four days later, after which it continued to be present for three weeks, when the patient left the clinic uncured.

In reading over the report of these 100 cases as summed up in the clinic history book I find the following: practically cured in three weeks, 22; cured in four weeks, 28; cases extending over four weeks, 17; cases leaving the clinic after one or two visits, 18; and cases under treatment at the present date, 15. Such a report can only be considered an "off-hand" one and not one of scientific importance. In fact, it is extremely difficult to make good statistics in this line of cases when the patients are all ambulants, as they do not look upon their sickness as anything more than a slight malady of trivial importance. In consequence of this they do not come steadily and do not attend to themselves properly. They often keep away from the clinic for weeks, only returning when the discharge is troublesome, and when it has diminished they often go on a "spree" and indulge in excesses which may bring it back again, as a discharge which has been absent for several days will frequently return after one drink of beer, wine, or spirits. These patients, also, at times leave the city for a few days or weeks, and consequently their treatment is interrupted. For this and many other reasons no sequence of cases is of great value, but rather selected ones, and the selection should be of those that have been under observation from nearly the beginning of the attack to the end, or at least for a more or less protracted period. It would, therefore, make our report of more value to those interested in the treatment of these cases if we were to cut it down. For of what interest is it to know that certain cases have been under treatment for over four weeks, or that they left the clinic after one or two visits, or are still under treatment, as it does not signify that they were cured or ever would have been.

The expression "practically" cured is also an indefinite one, although sometimes we have to take refuge behind it even at the present day. We can now say positively whether a case is cured or not, for in a case of cure the patient should be free from any disagreeable symptoms, should have no discharge, no flakes in the urine coming from the urethra, and no pus or flakes containing gonococci in the urine after massaging the prostate and seminal vesicles. In olden days physicians considered a patient cured when there was no longer any discharge to be noticed, and probably if this method of determination had been carried out in our clinics the percentage of cures would have been greater, and probably 50 per cent. of those coming regularly would have been considered cured in perhaps an average of four weeks; but the result of the treatment of those cases is now more exactly known, and statistics that were formulated before the days of the recognition of the gonococcus and the *tripperfaden* should no longer be quoted. Some of the cases considered cured or practically cured in the report had at the date of the last visit some of the following notes: (1) slight moisture at the meatus, first and second specimens of urine clear, no shreds; (2) slight moisture, urine clear, few shreds; and (3) no moisture, some shreds, urine clear. The first of these would be considered a cure if no pus or gonococci could be found in a smear of the moisture; the second would be considered a cure if no gonococci could be found in the moisture or shreds; and the third would be considered a cure if the shreds did not come from the urethra but from some inflamed surface above it, and there were no gonococci in the shreds. We all know that there can be a urethral moisture dependent purely upon functional trouble, such as spermatorrhœa and prostatorrhœa, and not upon any inflammatory condition, but the microscope can easily differentiate between them. If the urine is thick after the discharge has ceased the urethritis may be confined to the posterior urethra, and flow back into the bladder rather than forward. Such a return of the discharge would probably quickly follow the discontinuation of treatment and the centrifuged urine would probably show gonococci in its sediment. Therefore, in order to draw conclusions of some value we should only consider the cases that have been under treatment for three or more weeks, and leave out all those that made but one or two visits. If these two groups, consisting of 33 cases, be subtracted, and two more because there were no gonococci found present, we would have 65 cases to consider. Ten of these were cured positively in four weeks, that is to say, there was no discharge, the urine was clear and contained no shreds; 15 more cases were cured in six weeks; 20 more were practically cured in four weeks, that is to say, they had no discharge although there were a few shreds still in the urine or some cloudiness. The remaining 20, who were irregular in their attendance, came occasionally to the clinic during a period of from four to eight weeks, and finally wandered away with still some discharge and shreds present. This would make a list of 65 cases in which the results were as follows: Cases cured in four weeks, 10, or 15 per cent.; cases cured in six weeks and under, 15, or 23 per cent.; cases practically cured as there was no discharge though there were some shreds in the urine at the end of from four to eight weeks, 20, or 30 per cent.; cases not cured in from four to eight weeks, 20, or 30 per cent. It would not be fair, then, in considering the use of mercurol in urethritis to draw too hasty conclusions, but to study more carefully this compound in different strengths and mixed in different ways.

It has been noticed that solution of mercurol decomposes in from three to four days, and it therefore will be interesting to ascertain of what value it will be after decomposition has taken place.[1] Is the fluid, then, anything more than ordinary water? or does the precipitate contain particles of mercury which might irritate the urethral mucous membrane? The answer to these questions I cannot give, and will leave them as subjects for further investigation. I will state, however, that in some cases a 1 per cent. solution gave rise to a considerable burning sensation, while in others a 2 per cent. and stronger solution did not. It is probable that this depended a great deal upon the freshness of the solution, or it might have depended upon the part of the bottle from which it was taken—that from near the top being mild, while that from the bottom might have been stronger due to its containing particles of mercury.

One of the most valuable observations that I have made in the reading of this report is the fact that only two cases have suffered from complications, one having developed gonorrhœal rheumatism and the other epididymitis. This in itself would tend to argue much in favour of the use of mercurol, for where is there any other solution or mixture that has been employed in the treatment of these diseases which does not show a greater percentage of complications? When we consider that many writers claim that in 20 per cent. of all cases of urethritis epididymitis occurs, the rate of 1 per cent. which is reported in these cases certainly would seem to argue much in its favour as a harmless yet efficient injection. Another interesting feature is that in only one of the 100 cases was there any marked posterior urethritis, in which case there were the ordinary symptoms of frequency of urination, tenesmus, &c., which did not occur in the other 99. It is probable that in most cases of urethritis—that is, in from 80 per cent. to 90 per cent.—the disease travels down to the posterior urethra, but that in no more than 20 per cent. of them are there any disagreeably acute symptoms, while in this group of 100 cases only 1 per cent. have proved troublesome. Therefore, it would seem that mercurol probably quickly destroys the gonococcus, lessens the severity of the inflammation, and tends to prevent the development of

[1] Since writing this paragraph I have been informed by the manufacturers of mercurol that this difficulty has been obviated, and that the solutions are now more stable.

complications, but does not possess the power of entirely stopping the discharge in all cases; and it would therefore seem that after the discharge has developed into a moisture and gonococci are no longer found in it, or in urethral shreds in the urine, that it might be better to change from a mercurol solution to a mild astringent one.

In conclusion, it might be well to say from a comparative study of the different methods of treating gonorrhœa that it would seem that mercurol is an advance on the old methods of treatment by balsamics and astringent injections.

New York.

## BERI-BERI.

BY CECIL BULLMORE, L.R.C.P. & S. EDIN., L.F.P.S. GLASG.,
SURGEON TO THE FALMOUTH HOSPITAL.

FOR several years past it has been my lot in the course of ordinary professional work to have rather exceptional opportunities of observing and treating this somewhat obscure disease, and in view of the now not infrequent discussion as to its etiology, symptoms, and real character the following notes may be of some interest and possible value. When met with in Falmouth the disease is, as a rule, in an advanced state, and since we have generally only the comparatively uneducated observations of a captain or mate, or even fellow-seamen, on which to rely it is difficult to get a correct knowledge of its early history. On analysis of the facts that have come under my notice one of these two following conclusions is apparent—viz., (1) the beri-beri which reaches us is not the same as the beri-beri of the Malay Peninsula and elsewhere; and (2) beri-beri is not epidemic. Personally I incline to the former belief. I intend discussing the disease as it comes to us generally on vessels that have had a lengthy voyage and have passed through the tropics. Traders in the colder climates are far more liable to scurvy than to beri-beri, though, as is well known, the crews of American whalers are by no means free from attack. I have gathered that from 45 to 70 days out is the time when the disease first shows itself; the statement of captains that it seldom appears in the tropics but soon after leaving them is probably of no moment and only points to its slow onset. Another fact in support of an insidious attack is the statement that the manifestation of the disease is almost coincident with the appearance of the rice insect which is first seen in from 50 to 70 days.

Many theories have been advanced and all of them seem plausible enough till tested by the light of practical experience. Cornellisen and Sugensya go so far as to assert that the cause is a septic organism affecting clothes and woodwork. Now, during all the years that cases of beri-beri have been landed at the port of Falmouth no preventative means have ever been taken to check its spread. The patients have been admitted into the general wards of that most worthy institution the Royal Cornwall Sailors' Home, and not a single fresh case has occurred from infection. Then, again, ships that have landed sufferers have been known to go for years without a recurrence of the disease. For example, in 1896 a Norwegian barque was in at Falmouth with some of the crew down with beri-beri. She called again in December, 1899. She had been quite free from beri-beri in the long interval. Beyond the removal of the sick and the cleansing of the water-tanks nothing had been done on the occasion of her first call. Strange to say she was 120 days home on her second voyage from the same port whence three years before she had arrived with the disease.

To take another example, the German barque *Spica*, from Punta Arenas, put in here on Nov. 13th, 1897, with one case on board. I learnt from the patient who was landed here that he shipped at Punta Arenas where he had been in hospital to be treated for this very disease. He had lived and slept in the forecastle with the other sailors, all of whom were perfectly well on arrival here. I could give similar instances, but have, I think, sufficiently discounted the infection theory. Anderson attributes the cause to bad hygiene. This seems scarcely probable, as with very few exceptions it will be seen from the chart appended that the ships upon which cases of beri-beri have occurred were in a good sanitary condition although the ventilation might have been improved. The bilge-water, galleys, forecastle, and water-tanks were all in a satisfactory state, even when the majority of the crew were stricken down. I am certainly disposed to think that bad sanitation facilitates an outbreak of the disease by lowering the general health, but I do not think it causes it.

The captain of the Norwegian barque *Lotus*, 150 days home from San Juan del Sur, records that when in 33·34 south latitude the vessel was becalmed in a black fog; 14 days afterwards beri-beri appeared. In such a latitude the fog might have been of a malarial nature, and the incident might be quoted in evidence of Simmons's and Schebe's theory, but the several captains I have questioned merely look on this as a coincidence and can give no similar experience.

Ogata and Lacerdas suggest bad rice. To this supposition I do not attach much importance because (1) very little rice is eaten; (2) the captains invariably assert that the rice is perfectly good; (3) on examination I have always found it excellent on ships where beri-beri has broken out; and (4) out of 51 ships arriving here during 1899 with rice cargoes only four had cases of beri-beri on board. Pekelharing, Ogata, and Taylor all advance the theory that the anæmia is due to a micro-organism giving rise to a poison acting like muscarine and so causing acidity and disordered action of the sweat glands. Great authorities as these three undoubtedly are they nevertheless fail to find the same micro-organism. The first-named attributes the disorder to a diplococcus, Ogata to a bacillus, and Taylor to a spirillus. Other well-known authorities have failed to find any micro-organism at all.

In face of these different results of independent investigation it is hard to discriminate. Pekelharing says that diplococci are associated with the soil and overcrowded dwellings. Taylor maintains that spirilli are found in the soil, bad fish, and bad rice. These, though, compare unfavourably with the miasma theory of Simmons and Schebe. Let us take it for granted that the three authorities mentioned have found three separate micro-organisms which will produce the same effect, and also that the said organisms work in crowded dwellings and contaminated soil, and it obviously follows from the foregoing remarks that the incubation period is from 45 to 70 days. Now in comparison with enteric fever (from 5 to 21 days), malaria (from 5 to 21 days), and yellow fever (from 1 to 18 days), such a lengthy period seems unlikely. Then, again, how can this case be accounted for? A man brought home by the German barque *Spica* developed the disease on the voyage out from London before he could possibly have contracted it at any port of call. Unfortunately I could get no authentic information as to the food and sanitation of the vessel except that lime-juice was served out five days after leaving London.

As I have given my reason for doubting the theories of others it is right that I should suggest a cause myself. On British ships each man is supplied with one gill of vinegar a week, or half an ounce per day, and in the tropics lime-juice is also issued at the captain's discretion, failing the presence of a medical officer. Each man must have six ounces per week, making one and a half ounces of acidity per diem. Now when we consider what the effect of the tropical weather must have on tinned and salted meats, fruit, and vegetables, it makes me shudder to think of the decomposition and the manufacture of ptomaine which must go on—that is to say, during prolonged voyages of sailing ships through the tropics—and what a chance any alkaloids must have of asserting themselves in the disarranged stomachs of sailors who have been cooped up in a limited space on none too good a diet, who have had to drink tanked and often impure water, and whose bodies have been carefully prepared for fermentation and other disorders with vinegar and lime-juice. Let it not be thought that I am overstating the case. I am not. I merely give facts.

Now supposing our own toxic products are not ample enough to allow of this—which, by the way, is quite contrary to Sir T. Lauder Brunton's teaching—we might argue that the toxic alkaloids, such as muscarine, neurine, and neuridine, that one would be likely to absorb from such a diet as the ordinary sailor has might gain the upper hand. Pekelharing says it is due to a diplococcus acting like muscarine. Why not muscarine or one of its allies? We are well aware that acids taken in continued doses will disarrange the natural gastric secretion and cause fermentation leading to the production of gases and other noxious products as well as acids such as acetic, butyric, and lactic. Having established this fact we then come to consider the point of auto-infection. We are now comparatively alive to the important

results produced by the absorption from the intestinal canal of poisonous matters introduced from without, and we ought to be equally ready to appreciate the absorption by the intestinal canal of substances generated within, either by fermentation or imperfect digestion. It has been proved by recorded observations that sulphuretted hydrogen may be produced in the digestive tract, and Dremarquay has shown that it is very quickly absorbed into the blood. We are also aware that sulphuretted hydrogen will seize upon, and combine with, the oxygen, leaving the reduced hæmoglobin to be dissolved out of the corpuscles and diffused through the degenerated blood, both these conditions if carried to any extent being incompatible with life. Again, the citric acid of the lemon and the diluted acetic acid are known to have a peculiar deoxidising effect on the blood by converting the blood in part into a carbonate at the expense of the hæmoglobin. Thus $2K_3C_6H_5O_7 + O_{15}$ (from hæmoglobin) $= 3K_2CO_3 + 9CO_2 + 5H_2O$. Having reached this stage common sense must open our eyes to the fact that the lessening of the resistance to auto-infection is increased to a most dangerous extent. By this I mean the elimination of the toxic products by the excretory organs and the destruction of the said products by oxygenation, which consists in a continuous combustion of the leucomaines and the other animal alkaloids by the oxygenation of the blood in whose current they are consumed and burned.

As regards the symptoms, there is but little chance of gaining any definite or reliable information of the early history of the disease because the stories of the patient and his captain seldom agree. During the first week or few days the sufferer complains of a general malaise, loss of appetite, headache, &c. There is little, if any, rise of temperature. One case of 100° F. and one of 99° F. have been recorded by captains who kept a chart. I have myself taken the temperature in between 60 and 70 cases, all in a somewhat advanced stage, and I have come to the conclusion that a rise of temperature is an exception and not the rule. The malaise is generally followed by a strange loss of power in the lower limbs and complained of at first as a stiffness. This loss of power slowly increases, so that the men have to hobble about as best they can with the aid of ropes, deckhouses, hatches, &c. About this time, too, in about 50 per cent. of the cases a numbness of the lower extremities is often felt and a tickling or pricking sensation is complained of. These symptoms are generally followed by an œdema of the dorsum of the foot or ankle which spreads slowly up the limbs to the trunk. I once saw a patient who was simply water-logged. He would "pit" anywhere below the neck, but his face and head were quite natural. In the majority of cases the feet and legs are attacked first, but I have seen anasarca of the scrotum, abdomen, and chest with no œdema whatever in the legs. Many cases even have no œdema at all and are evidently the dry beri-beri of some authorities who state that the patients

A CHART ILLUSTRATING FEATURES IN CASES OF BERI-BERI ON BOARD 20 SHIPS.

suffer severely from neuritis. When the œdema subsides the true state of the neurotic mischief becomes manifest; the legs are most sensitive to tactile impression, and have a dull, aching pain which the sailors bitterly complain of.

To tabulate further and general symptoms for the sake of brevity and conciseness, the tongue is generally clean, pale, flabby, and frequently tooth-indented; the gums are pale, not spongy or swollen; the voice is natural; the breath is offensive, as from an ordinary disturbed stomach; the bowels are as a rule freely open (in a few instances they are irregular); and the urine in amount is normal and its colour is bright. I have tested 20 samples and found albumin in two of them. A colleague of mine had one bad case of albuminuria to treat. With regard to the sweat glands, Pekelharing speaks of the disorder of these glands. I believe they are active in the early stages as I have had many complaints of cold sweats suffered then. The pulse is full, strong, and slightly quickened, ranging from 90 to 120. The respiration is quickened, but inspiration and expiration are usually properly proportionate. There is palpitation of the heart and epigastric pulsation is felt. The commonest forms of cardiac lesion in my experience have been dilatation of the left ventricle and mitral regurgitation, though I have heard murmurs over most of the orifices and bruit of the carotids. The pupils react normally. I have not come across a case having Argyll-Robertson's pupil. The smell is normal. The sphincters are unaffected. The deeper reflexes in well-marked cases are lost but I have got distinct knee jerk and ankle clonus in mild cases. The extensor muscles quickly atrophy. Foot-drop is common and gives the patient a characteristic gait; he lifts his knees high and seems to drop his foot down anywhere and with no apparent control. I have not seen more than one well-marked instance of wrist-drop and but a few slight ones. I cannot say if Romberg's sign is present or not, but closing the eyes and turning will ensure a fall, probably from weakness.

In conclusion, I do not for a moment believe that beri-beri, as we know it, is infectious or contagious; in fact, I do not consider that what we in England call beri-beri *is* beri-beri—at least, not such as is met with in foreign countries. I put forward a theory that the disease that reaches us is due to an alkaloidal poison fanned into flame by the disarranged digestion of sailors who are kept on improper diet, and in that case by properly dieting the vessels and supplying the captains with iron and digitalis tabloids the disease in all probability would be reduced to a considerable extent if not stamped out. The necessity for the proper dieting of persons on board vessels is of course no original suggestion of mine; it has answered admirably in the Japanese navy and I see no reason why the British sailor should not have a similar fortunate experience.

Falmouth.

## MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

### A FATAL CASE OF POISONING BY PARALDEHYDE.

BY LOVELL DRAGE, M D. OXON., M.R.C.S. ENG.

AS I believe that there is no case on record of death from poisoning by paraldehyde I send the following for publication in THE LANCET, having held an inquest upon the body of a woman who died from this cause.

The history of the patient was that she was 46 years of age and had suffered for some years from chronic emphysema, chronic bronchitis, and heart disease. She had been in the habit of using drugs of various kinds to excess. She had recently returned home from abroad, and on the day when a nurse took up her duties there was in the house a three-ounce bottle of paraldehyde besides another bottle containing six ounces of the drug. According to the nurse's statement, she asked the medical man in attendance how much of this drug was to be administered, and the order was two teaspoonfuls in a wine-glassful of water thrice during the night. However, in the course of the 24 hours five doses of two drachms each were administered. The patient had a constant craving for the drug. At the beginning of the next 24 hours one teaspoonful was given and this was repeated in about four hours' time and again after another four hours had elapsed. Roughly speaking, from midnight to midnight 10 drachms of the drug were used and in the next nine hours three drachms. I am inclined to think that possibly nearly twice as much was really given, but this is only a guess. The symptoms noted by the nurse were restlessness and some degree of delirium and constant craving for the drug.

About two hours after the nurse had given the last dose the patient possessed herself of another bottle of the drug containing at least six ounces. The bottle had a label pasted on it; on the label was printed the name of a respectable firm of drapers in London and the name of a man who was presumably a qualified chemist. Nothing but the word "Paraldehyde" was written on the label. The nurse estimated the quantity of the drug consumed by the patient at about two ounces. After the patient had taken this the nurse found on returning to the room that her condition was serious and she sent for a medical man. The practitioner who was in attendance and who had seen the patient on the arrival of the nurse was not at home, and his assistant, who came to the inquest, attended instead. This gentleman noted the following symptoms: unconsciousness, profuse perspiration, rather deep cyanosis, intermittent pulse, and shallow breathing, about normal in time. He administered strychnine hypodermically and some improvement in the patient's condition took place, but death occurred about three hours after the lethal dose was taken. Unfortunately, the nurse's statements, except as to the condition of the patient, were for the most part uncorroborated. According to this statement 13 drachms of the drug were administered in the course of 33 hours; at all events, enough was administered to produce the mental condition associated with the action of the drug before the patient herself took the fatal dose which was possibly less than the amount estimated.

Binz, in his work on Pharmacology, mentions that according to the German Pharmacopœia 85 drops are the maximum single dose and 170 drops the maximum quantity to be given in 24 hours. Having used the drug in my own practice to a considerable extent these doses are, in my opinion, correct, and I venture to call the serious attention of the members of the medical profession to the deplorable condition of affairs illustrated by the facts of this case. It must be common knowledge that drugs of all degrees of potency can be obtained by the ignorant in unlimited quantities from all sorts of sources. Nurses not infrequently bring them when they come into the houses of sickness and recommend them to the patients whom they come to nurse. The habit of taking drugs, especially those which act on one or other part of the nervous system, is on the increase, and I ask in all seriousness, Are the members of the medical profession sufficiently careful in their methods of prescribing, and especially with reference to the ordering, of proprietary remedies and drugs in the form of compressed lozenges and other articles of that genus? The fact is, so many lethal drugs, or drugs that may be lethal if not prescribed with adequate precaution, are introduced and advertised as harmless that it behoves us to proceed warily.

Hatfield.

### A CASE OF PHOSPHORUS POISONING.

BY WILLIAM E. NEWEY, M.R.C.S. ENG., L.S.A.

THE following case may prove useful and interesting some of the readers of THE LANCET. On August 11th I was called to see a man who was suffering from vomiting and intense burning pain in the stomach and bowels. His history was that on the 7th, when "in drink," he had swallowed three-pennyworth of rat-killer. Immediately after swallowing it he complained of violent pain in the stomach and sickness. He was given salt and hot water, after which he was very sick and vomited freely and expressed himself relieved. On the next day he was a little better, although he felt far from well; he, however, dressed himself and walked about. On the 11th he was taken much worse and I was sent for. When I saw him his temperature was normal, he was quite conscious and coherent, and his pulse was 90. He complained of thirst, constant vomiting, and great pain in the stomach and abdomen. An examination of the vomit proved it to consist wholly of altered blood of a very dark colour. His stools also were dark and pitchy in character. He was given the usual remedies, but they were of no avail,

and he quietly sank and died on the following Tuesday, the 14th, having lived exactly a week after swallowing the poison. The vomiting of dark-coloured blood continued up to the time of his death.

A post-mortem examination was made 24 hours after death. The weather was very warm but there were no signs of putrefaction. Very slight rigor mortis, if any, was perceptible. The body presented a most curious and interesting appearance. The whole of the neck in its entire circumference, back, and sides bore the appearance of having been stained in a deep solution of Prussian blue, the colour being most intense and brilliant; it was not mottled but uniformly stained. The arms and legs showed an icteric tinge; their superficial veins looked as though they had been injected with a solution of Prussian blue paint and were most beautifully mapped out. On opening the body the chief points noticed were as follows. The stomach contained half a pint of liquid blood; it was deeply coloured blue; it showed softenings and ulcerations in patches, and it was thickened in other parts. The whole of the intestines showed signs of an irritant poison; they were deeply pigmented with the colour, and the contents were dark and pitchy. The transverse colon was intensely inflamed and the fat of the great omentum showed bright extravasations of blood and was most striking in appearance. The heart, liver, and kidneys showed signs of commencing fatty degeneration. The lungs and the liver were deeply coloured blue. The brain was rather anæmic, soft, and almost diffluent in parts.

Dudley.

## MULTIPLE WARTS CURED BY REVACCINATION.

BY J. DIBBLE STAPLE, M.R.C.S. ENG., L.S.A.,
PUBLIC VACCINATOR FOR THE ASHLEY DISTRICT OF THE BRISTOL UNION

THE relatives of a girl, aged 15 years, consulted me in reference to a number of warts which she had on both of her hands. She had herself counted 94 on the right hand. Her parents had tried several "popular" remedies but with no satisfactory result. Having recently read in one of the medical journals that a number of warts had been cured in a patient who had been revaccinated, I determined, with the consent of the relatives, to give this treatment a trial. I revaccinated the patient on June 1st. The operation was successful, but no effect was produced upon the warts until seven weeks after, when, to use the description of the patient, the warts gradually "disappeared," leaving temporary white spots, and when I saw the patient on August 30th she had no trace of them.

Bristol.

VACCINATION IN MERTHYR TYDVIL.—At the meeting of the Merthyr Tydvil board of guardians held on Sept. 1st it was reported that for the last six months of 1899, in the various districts of the union, there had been 2182 births. Of these children 1484 were successfully vaccinated, three were insusceptible, 437 died unvaccinated, and 117 were medically postponed. There were 12 cases of conscientious objection, and 85 remained unaccounted for. The cases unaccounted for occurred in Merthyr and Gelligaer, and the clerk was instructed to write to the vaccination officers of these respective districts calling their attention to the large proportion of these cases.

FOREIGN UNIVERSITY INTELLIGENCE.—*Athens:* A chair of Hygiene and Bacteriology has been created to which Dr. Savas, a military staff surgeon, has been appointed.—*Berlin:* Dr. Emil Grunmach has been promoted to an Extraordinary Professorship of Medicine.—*Bologna:* Dr. Nicola Giannettasio has been recognised as *privat-docent* of Clinical Surgery and Operative Medicine.—*Greifswald:* Dr. Hugo Lüthje of Marburg has been recognised as *privat-docent* of Internal Medicine.—*Halle:* Dr. Fritz Haasler, *privat-docent*, has been granted the title of Professor.—*Heidelberg:* Dr. Fürbringer of Jena has been appointed to succeed Professor Gegenbaur in the chair of Anatomy.—*Munich:* Dr. Moritz Hofmann has been appointed to the chair of Forensic Medicine.—*Rome:* Dr. Lorenzo Bonomo has been recognised as *privat-docent* of Medical Pathology, and Dr. Mario Ponticaccia as *privat-docent* of Pediatry.—*Strasburg:* Dr. Edwin Faust has been recognised as *privat-docent* of Pharmacology.—*Utrecht:* Dr. Ziehen of Jena has been appointed to the chair of Psychiatry.

## WESTMINSTER HOSPITAL.

### TWO CASES OF GANGRENE OF THE LUNG TREATED BY PARTIAL EXCISION.

(Under the care of Dr. W. MURRELL and Mr. WALTER SPENCER.)

THE rarity of gangrene of the lung is indicated by the statistics of Waller[1] who in 2663 post-mortem examinations, including 895 cases of pulmonary disease, found only two of gangrene—i.e., less than 0·1 per cent. of the whole number; but Boudet[2] in 511 post-mortem examinations found nine cases of gangrene. The value of operation in pulmonary gangrene is undoubted. Reclus[3] says that in cases treated by operation the mortality is only 25 per cent., while in cases treated medicinally it is 75 per cent.

CASE 1.—A labourer, aged 32 years, was admitted into the Westminster Hospital on June 13th, 1900, complaining of pain in the right side which was increased by coughing. He stated that he had been perfectly well until three months previously when he contracted a cough which was attended with much expectoration. He had lost flesh and his appetite was bad. On admission it was found that there was dulness all over both backs with scattered moist sounds. At the right base posteriorly the dulness was more intense and the respiratory sounds were absent although friction could be detected here and there. The heart sounds were normal. The temperature ranged from 99° F. in the morning to 101° in the evening. The expectoration was of a peculiarly offensive character and the odour, in spite of the free use of antiseptic inhalations, could be detected in the corridors outside the ward. There was no doubt that the base of the right lung was gangrenous. The patient continued to lose flesh, was unable to take nourishment, and was in a critical condition. On the 28th the temperature ranged from 98·2° in the morning to 101·4° in the evening. The pulse was 112, feeble, and easily compressed and the respirations were 36. The expectoration, which could be separated into the typical three layers, contained streptococci and sarcinæ but no tubercle bacilli. The specific gravity of the urine was 1020; it was acid and contained neither sugar nor albumin. On June 29th Mr. Walter Spencer resected the seventh rib on the affected side and removed a large quantity of fœtid pus with portions of gangrenous lung. The pulse on the evening of the operation was 118 and the respirations were 56. The following night the temperature was 100°, the pulse was 134, and the respirations were 49. The patient rallied for a time, but died on July 3rd.

*Necropsy.*—At the post-mortem examination the following appearances were found. There were adhesions in both pleural cavities, but most extensively on the right side. On the right side behind the pleura was gangrenous and sloughy over a space as large as a man's hand. The upper lobe of the right lung was normal throughout but œdematous. The middle and lower lobes were coherent and in the lower part of the latter there was a gangrenous focus of the size of a Tangerine orange. Around, the lung was semi-solid with a tendency to break down. The left lower lobe showed a small cavity in the upper part of a distinctly pyæmic character. There was no evidence of tuberculosis in the lungs. Around the cavity in the left lung the pulmonary tissue was intensely œdematous and looked as if it were in a state of grey hepatisation, but it still contained air as indicated by the fact that some portions did not sink in water. The larynx, trachea, and bronchi were full of blood-stained mucus. There

[2] Archiv Générales, 1843, vol. iii.
[3] Revue de Thérapeutique Médico-Chirurgicale, Nov. 1st, 1836.

was no dilatation of the bronchial tubes. The bronchial glands were considerably enlarged.

CASE 2.—A married woman, aged 28 years, was admitted into the Westminster Hospital on June 2nd, 1900, suffering from pneumonia involving the base of the right lung. Her family history was not good; her father, sisters, and one brother had died from chest complaints which were probably tuberculous in origin, although the evidence on this point was inconclusive. She was taken ill suddenly on May 25th; there was no rigor, but there was acute pain on the right side which confined her to bed. On admission her temperature was 101·4° F. and on the following evening it was 102·8°. The expectoration was glutinous and rusty and it contained no tubercle bacilli. On examination it was found that there was deficient movement over the whole of the right side. There was a patch of dulness over the fifth and sixth ribs laterally and posteriorly; the dulness extended from the base of the lung to as high as the angle of the scapula. Vocal fremitus was absent and no respiratory sounds could be detected at the base, but in the upper part of the lung there were abundant moist râles. There were no friction sounds and the heart was not displaced. The left lung was apparently normal. No tubercle bacilli were found in the sputum. The urine had a specific gravity of 1026, was acid, and contained some albumin, but no sugar. The patient had no crisis and the temperature usually reached 103° in the evening. On June 18th it was noticed that dulness at the base of the right lung as high as the angle of the scapula still continued. Over this area vocal fremitus was absent and the breath-sounds were only faintly audible. Whilst the patient was being percussed she had a violent fit of coughing and expectorated a considerable quantity of thick yellow matter having a distinctly gangrenous odour. On the 24th, there being no improvement in her physical signs, the needle of a hypodermic syringe was inserted and some yellow offensive pus was withdrawn. On June 26th, under nitrous oxide gas and ether, Mr. Walter Spencer removed a portion of the eighth rib in the post-scapular line on the affected side. A cavity was opened which involved the base of the lung and communicated with a bronchus full of pus and gangrenous sloughs. The sloughs were drawn out, iodoform emulsion was injected, and an iodoform plug was inserted. In the evening the temperature was 100°, on the following day it was 100·4°, and on the third day 101·2°. The wound gradually healed and the discharge became less, but the progress towards recovery was slow. On July 26th tubercle bacilli were found in the expectoration in small numbers. There was a sinus about four inches in length and half an inch in diameter. This should have been opened up, but the patient declined a second operation and was sent to a convalescent home.

*Remarks by* Dr. MURRELL.—Cases of gangrene of the lung are not common. I have looked through the records of the hospital for a period of ten years and find that during that time 10,000 medical and about the same number of surgical patients have been treated in the wards. I have consulted the records of 1400 post-mortem examinations made during the last seven years. Out of this large number of cases I find only one of gangrene of the lung. I do not attach much importance to these figures, for there may have been many other cases tabulated under the name of the primary disease. Still the fact remains that gangrene of the lung is not a common disease. Some people would go even further and say that it is not entitled to be regarded as a disease at all, seeing that it never occurs as a primary affection. It may follow in the wake of acute lobar pneumonia and less commonly of phthisis. It may be lighted up by the fœtid contents of a bronchiectatic cavity or it may be due to embolism or thrombosis of the pulmonary artery. It may follow aspiration pneumonia and is sometimes the result of the inspiration of septic material originating in a cancer of the lung or larynx. Sometimes there is a direct invasion of the lung by contiguous diseases such as cancer of the œsophagus or of an abscess or suppurating hydatid. It may be a complication of pyæmia, otitis media, puerperal affections, or even bed-sores. In exceptional cases it is met with in the course of convalescence from long protracted illnesses, such as enteric fever. These exciting causes are common enough, and yet, as we have seen, gangrene of the lung is not common. It is a somewhat curious coincidence that these two cases should have occurred concurrently. In the majority of cases there is some predisposing cause, and this may be senile degeneration, marasmus from one of the intoxications, such as lead or mercurial poisoning, or alcoholism, or syphilis, or diabetes mellitus. In neither of these patients was there apparently any definite predisposing cause. The man was in the prime of life and there was no history of any previous illness. He was not alcoholic and the urine contained neither sugar nor albumin. In the case of the woman there was albumin in the urine, but it was small in quantity and disappeared before she left the hospital. The gangrene may be general, affecting the whole lung, but commonly there are only one or two necrotic foci. As a rule the gangrene is limited in extent, but rarely by a separating capsule. The symptoms are usually preceded by the symptoms and physical signs of the disease to which it is secondary. For example, it may begin with the physical signs of pneumonia, or phthisis, or malignant disease of the œsophagus. The characteristic sign is the intensely fœtid odour of the breath and expectoration. There is a fœtid odour in bronchiectasis, in advanced phthisis, and even in chronic bronchitis, but it never has the peculiar offensiveness of gangrene of the lung. In gangrene the expectoration contains not only the débris of the lung tissue but not uncommonly fragments of the lung itself. The general symptoms are a moderate degree of fever, a quick pulse and great depression, and constitutional disturbance. Medical treatment is of little avail, although antiseptic inhalations of carbolic acid, creasote, guaiacol, eucalyptus, and especially formic aldehyde may mask the smell. The only real relief and the only hope of recovery is the removal by surgical means of the gangrenous portion of the lung. This is the treatment which has been adopted in these cases.

## LIVERPOOL WORKHOUSE HOSPITAL.

### TREPHINING AND DRAINAGE IN AN APPARENTLY MORIBUND CASE OF STATUS EPILEPTICUS; RECOVERY.

(Under the care of Dr. W. ALEXANDER.)

IN the following interesting case the epileptiform convulsions appeared for the first time at 36 years of age and this fact was in itself very suggestive of a definite cerebral lesion, especially as there was a history of head injury. The affected area was localised by the right-sided twitchings and the correctness of the diagnosis was proved by the success of the treatment. It is probable that several distinct conditions are included under the term "status epilepticus" and only some of these are amenable to surgical interference. For the notes of the case we are indebted to Dr. W. T. D. Allen, senior resident medical officer.

A woman, aged 36 years, was admitted into the Liverpool Workhouse Hospital on July 4th, 1900, in a semi-unconscious state, suffering from very severe epileptiform convulsions. From her previous history the patient appeared to have been in good health until the previous February except for occasional attacks of articular rheumatism. She had been very much addicted to drink and in February she was taken into custody for this cause, and then it is stated that a policeman struck her on the head with his bâton. Her head became swollen and she was treated in the prison hospital. After two weeks in prison she was transferred to the workhouse hospital where she had an epileptiform fit which lasted for 15 minutes. The convulsions involved the limbs on both sides of the body and the patient was in a rather stupid condition for a day and a half after the fit. She made a gradual recovery and was able to resume her occupation in 10 days. She had never had a fit of any kind previously to this time. During the next four months she was in fair health except for a pain in the head which was at times very severe. On July 1st the convulsions began again and continued at very short intervals for four days until she was taken to the workhouse hospital. On admission there the patient was semi-unconscious and during 20 hours had over 40 fits. These began with twitching of the muscles of the lower part of her face on the right side and then spread to the right hand, arm, and leg. The corneal reflex was absent and the pupils were directed towards the right side. Each fit lasted for three or four minutes. On July 5th the patient, who appeared to be moribund, was trephined by Dr. Alexander over the upper motor area on the left side. The dura mater bulged into the opening when the piece of bone one inch across was removed. The dura mater was opened; the cerebral veins were much enlarged and lay bathed in a layer of fluid a quarter of an inch thick. The

fluid was held in position in the meshes of arachnoid and pia mater and when the meshes were pricked the fluid ran away in a clear sparkling stream. As the brain seemed to be healthy beneath and there were no signs of any gross lesion such as cerebral tumour or bone injury or disease, a double cyanide gauze drain was placed in contact with the opening in the membranes and the rest of the wound was closed. After the operation the patient had several severe fits and these continued for three days, but gradually diminished in severity and frequency. Since then she has had no return of convulsions and the pains in her head, which were at first troublesome, have passed away. The scalp wound is now healed and the patient is quite well and strong.

*Remarks by* Dr. ALEXANDER.—In the presence of deep unconsciousness in status epilepticus the medical man often feels quite helpless. Bleeding is often useless because the blood will not flow and oxygen or chloroform makes no impression. In such cases the compressed cerebral hemispheres may be relieved, either, as in this case, by drainage of the serous effusion that sometimes exists or in others by the venesection of the congested cerebral veins. The operation itself under aseptic precautions is so harmless that its performance is more than justified under such serious conditions as the above case presented.

## GENERAL HOSPITAL, BIRMINGHAM.

### A CASE OF THROMBOSIS OF THE LEFT VENTRICLE WITH MULTIPLE EMBOLI AND GANGRENE OF THE LEGS.

(Under the care of Mr. T. F. CHAVASSE.)

FOR the notes of the case we are indebted to Mr. F. V. Milward, resident surgical officer.

The patient was a countryman, aged 57 years; he was well nourished and to all appearances must have been robust until the present illness commenced. He stated that he had never been ill in his life. Three weeks before his admission to hospital on July 12th, having previously had some indefinite pains in his legs, he noticed that his right foot had become cold in the night. Blueness and mottling succeeded the initial pallor and he was brought to the hospital with well-marked gangrene of the right foot. There was no line of demarcation, nor did one form subsequently, and putrefactive processes never became much advanced, the skin being free from blebs. Constitutional disturbance was more severe than the local condition seemed to warrant. The patient was apathetic, the pulse was very feeble, the tongue was furred, and diarrhœa was present. The urine contained a cloud of albumin and many granular casts, but no sugar. No abnormal sounds could be detected either in the heart or the lungs. Two days before death gangrene made its appearance in the left foot and leg, and this, together with the cardiac depression and the presence of albumin in the urine, put all idea of surgical treatment out of the question. The patient gradually sank and died on the 16th from exhaustion.

*Necropsy.*—A post-mortem examination made on the 17th revealed the following appearances. There were well-marked gangrene of the left foot and leg and early gangrene of the right foot. The heart weighed 14 ounces. The left ventricle upon being opened was found to contain an ante-mortem clot of the size of a hen's egg; it was somewhat pyriform in shape, the base being attached to the apex of the ventricle and obscuring the posterior set of musculi papillares and chordæ tendineæ, so that its apex almost touched the posterior flap of the mitral valve. There was some chronic thickening of the aortic and mitral cusps, but there were no recent vegetations. The kidneys contained numerous infarcts of all sizes and in various stages of organisation. The spleen (five ounces) was converted entirely into one large infarct. There was a small and quite recent embolus in the left middle cerebral artery. An examination of the vessels of the limbs showed complete thrombosis of the veins in the left leg from the middle of the thigh downwards. The thrombus was becoming organised. There was also thrombosis of the left posterior tibial artery and of the right popliteal artery. No emboli were discovered in either vessel, but they had probably become indistinguishable through subsequent organisation of the thrombi.

# Reviews and Notices of Books.

*The Medical Diseases of Childhood.* By NATHAN OPPENHEIM, A.B. Harv., M.D. Coll. P. & S., N.Y., Attending Physician to the Children's Department of Mount Sinai Hospital Dispensary. Illustrated. New York and London: Macmillan Company. 1900. Pp. 653. Price 21*s.*

THE object of the author of this work has been to write a book on the diseases of children which will tend to promote a greater use of logic and a lessened reliance upon empirical methods than have formerly been common. He quite rightly draws attention to the fact that the tendency of our thought in the present time is in the direction of the accurate recognition of abnormal conditions, but we cannot agree with his deduction from this statement. He says: "For when this is accomplished (viz., the accurate recognition of abnormal conditions), the treatment, so far as it is elaborated, follows as a matter of course." It must be confessed that although our knowledge of pathology and bacteriology has greatly advanced, yet in many instances our therapeutics have not followed that advance. That further investigation may bring us eventually nearer to such a desideratum we do not deny, but at present the expression "as a matter of course" is utopian. Dr. Oppenheim goes on to remark: "The greatest stress in modern medicine has been laid upon the necessity of depicting lesions in the most graphic manner possible. Following out this idea the whole available space for illustrations in this book has been given up to micro-photographs of pathological sections, which have been thought to have a keener and greater didactic value than pictures of instruments, photographs of patients, and representations of surface changes." The author may certainly be congratulated on the result. These micro-photographs are one of the principal features of a very good book. They have been beautifully reproduced and they form one of the best series of such photographs which we have seen. The majority of micro-photographs leave much to be desired, but in those now before us the details are most plainly delineated, and characteristic specimens have been selected. It is an excellent plan to insert a micro-photograph of the normal structure of each organ, as is here done; it is most useful for comparison, and more especially is this the case with the stomach and intestines. These normal histological specimens are also beautifully reproduced. There are 101 original illustrations in half tone. Some of these are particularly good, such as the micro-photographs representing acute yellow atrophy of the liver, atelectasis with compensatory emphysema, and epidemic cerebro-spinal meningitis.

The clinical descriptions throughout the work are uniformly good and the pathology and etiology are thoroughly up to date. Some of the therapeutical measures suggested will hardly commend themselves, however, unless all other means fail. Lavage in various diseases of the stomach in the adult is strongly recommended by some authorities, but the majority of practitioners prefer to employ less unpleasant and usually equally efficacious remedies; much more would this principle hold with children. Dr. Oppenheim, however, advises lavage in the chronic gastritis of children and his description of the process would make the practitioner pause before adopting it. He adds: "As it may be necessary to continue this treatment for weeks the mother or nurse may be instructed in its details." Our sympathies certainly lie with the little patient. For purposes of differential diagnosis in cases of gastric disorders Dr. Oppenheim states that one of the best methods of differentiation is by means of a test meal, which is to consist of milk in infants, of bread-and-milk in somewhat older children, and of milk, bread, and meat in children of eight

or more years. Such methods of diagnosis, however, have not found general acceptance and the general belief is that equally good results may be obtained, except in very few cases, by means less calculated to inconvenience the patient.

Taking the book as a whole we have perused it with much pleasure. It is well written and we can cordially recommend it to those who wish special information in the medical diseases of childhood.

---

*Practical Manual of Diseases of Women.* By H. MACNAUGHTON JONES, M.D., M.Ch. R.U.I. Eighth edition, revised and enlarged. With 640 Illustrations and 28 Plates. London: Baillière, Tindall, and Cox. 1900. 8vo, cloth. Pp. 947. Price 18*s.* net.

THE eighth edition of this book certainly does credit to the publishers and printers. It is issued in a much more convenient size than was the last edition, and the binding and type leave little to be desired. When, however, we critically examine the part played by the author we must confess to a considerable amount of disappointment. We will at once admit that we have read many parts of the book with much profit and interest. It is not intended, however, solely for the specialist, but, as the title-page tells us, for the student and practitioner, and it is from their point of view that it must be judged. That the book contains an immense amount of information no one can deny. That such information has been arranged in a form suitable at any rate for the student few, we think, would be prepared to maintain.

The book is, as a manual, almost too much up to date. It contains practically everything new of any importance or otherwise that has been published in gynæcology since the last edition appeared. The result is that not a few theories, operations, and modes of treatment are included the actual value of which at the present time is quite uncertain, such, for example, as the vibration treatment of Jayle and De la Croix de Lavalette for uterine fibroids and adnexal affections. Many of the old statements to which we called attention as being present in the last edition are yet to be found. Dr. Macnaughton Jones still believes, apparently, that perimetritis, pelvic phlegmon, and uterine fibroids are amongst the results, direct and indirect, of uterine versions and flexions. It would be interesting to know the facts upon which these statements of the author are based. Several similar instances could be adduced, but these are, after all, but small matters and of but little weight in judging of the real merits of the book. The author has visited the clinics of most of the leading foreign gynæcologists and the experience gained he has included in various portions of his work. We do not remember ever to have seen a text-book in which the excerpts from other writers exist in so great an abundance as in this. As a means of ready reference for such gynæcologists as are unable to gain access to or to read the various extracts in the original the advantages of the work are undoubted. The want of proportion that exists between various chapters and sections is, however, very striking. A full account is given of the rare tumours known as endothelioma and gyroma, but when we turn to what is perhaps the most important part of any work on gynæcology —the chapter on Cancer of the Uterus—we find a curiously confused and involved account of medullary cancer, scirrhus, carcinoma, and epithelioma or cancroid, without any attempt being made to distinguish clearly between the pathological and clinical varieties of the disease.

This new edition certainly bears eloquent testimony to the author's unbounded industry, but it is at the same time a striking example of how little industry avails in the production of a really good work unless it be combined with a systematic method and some power of determining the relative values of various facts and theories. The illustrations are very numerous and some of them are very good.

---

*Encyclopädie der Haut- und Geschlechts-Krankheiten.* (*Encyclopædia of Diseases of the Skin and Generative Organs.*) Edited by Professor LESSER. Leipsic: F. C. W. Vogel. 1900. Crown 4to. Pp. 548. Price 30 marks.

THE problem of how to keep the practitioner in touch with the vast and rapidly-growing store of medical knowledge becomes more difficult every year. The additions to it are unlimited and the practitioner wishes, or at all events is expected, to know much more than he and his patients were content with a few years ago, yet the number of books he will buy are limited by considerations of expense. Two coöperative methods of dealing with the difficulty are in vogue. In the one a "system" consisting of a number of more or less comprehensive essays by the different contributors is produced; in the other a dictionary is compiled. Each plan has its good points, and though personally we think that the "scrappiness" of the latter is not compensated for by its advantages, such as facility of reference and necessary conciseness, we admit that it is largely a matter of taste as to which of the two is to be preferred.

The editor of the volume before us has dealt with the problem on the lines of a dictionary with considerable success. He has been fortunate enough to secure the services of an able staff of contributors, among them Professor Finger, Professor Neisser, Professor Seifert, Professor Paschkis, and Professor von Zeissl, to mention only two or three at random, and the result of their labours is an excellent book. It resembles Quain's "Dictionary of Medicine" more perhaps than any other English work, but is on a larger scale. It is impossible in the space at our disposal to criticise in detail the work of the large number of writers employed (they number no fewer than 42). It varies in quality naturally, but on the whole maintains a high level and is thoroughly practical throughout. The articles are written clearly and tersely and on the subject of treatment both sections, that on dermatology in particular, are unexpectedly full. It has, however, two serious faults. The principle of the subdivision of labour is carried to an excessive degree. In a cursory examination we have found no fewer than 14 writers on syphilis and doubtless many more could be found by further research. The general course of the disease is described by Blaschko, galloping syphilis by von Zeissl, the congenital variety by Caspary, Lustgarten's bacillus by Rille, laryngeal syphilis by Heymann, syphilitic disease of the heart by Mracek, of the ear by Jansen, of the mouth by Seifert, of the eyes by Greeff, of the kidney by Ullmann, of the nerves by Laehr, of the bursæ by Isaac, leucoderma by Schäffer, while we are indebted to Wolff for an account of the principles on which the disease is treated. With such a multitude of contributors repetition is unavoidable and that there should be as little as there is speaks volumes for the editor's skilful supervision. One of the best articles in the volume is the one on Ear Disease by Dr. Jansen which we have just mentioned, and it is the only one to which is appended a list of references to current literature. This deficiency in bibliography is a grave defect in the book. The text cannot possibly cover more than a portion of the subjects dealt with, and the book as a work of reference loses half its value if it fails to indicate where further information may be found. In spite of these shortcomings the volume will be found to be a convenient and trustworthy cyclopædia. It forms one of a series of medical encyclopædias in course of publication by Vogel of Leipsic. Two volumes on midwifery and gynæcology and diseases of the ear have already appeared, while three others on diseases of the eye, hygiene, and general surgery are in the press. Each volume is quite

independent of the others, and the whole, judging by the sample before us, should form a most valuable addition to medical literature.

---

*Étude sur la Lèpre au Brésil.* (*A Study of Leprosy in Brazil.*) By Dr. JOSÉ DE MAGALHAES. Rio de Janeiro: Pereira Braga and Co. 1900. Demy 8vo. Pp. 186.

THE object of this book is to combat some of the conclusions arrived at by the Conference on Leprosy held at Berlin in 1897. The irritation left by this (in some ways unfortunate) conference lends a tone of bitterness to the author's remarks, which is accentuated, perhaps, by the consciousness that the majority of leprologists have abandoned the views which he holds and he himself is a voice crying in a heedless wilderness.

Dr. de Magalhães firstly holds that leprosy is not due to the bacillus lepræ on the ground that even, he says, in tuberculous cases it frequently cannot be found, and when found can neither be cultivated nor reproduce the disease by inoculation. He does not believe it to be contagious because in Brazil, where lepers mix freely with other people, the disease does not spread. Some Brazilian writers disagree with him here, but these persons he regards as unpatriotic. "See," he says sadly of one of them, "how a Brazilian furnishes arms against his own country." Finally, he thinks the disease is hereditary in a wide sense of the word—i.e., that leprosy may be transmitted directly or may alternate with neuroses such as epilepsy. Without any hereditary transmission at all, he further says, it may be produced by improper diet, long exposure to damp, "emotions sad or keen, trauma, &c." In face of this list with the comprehensive "&c." at the end of it, that we are not all lepers is owing obviously only to the miraculous intervention of Providence.

Leprosy, we are told, flourishes in Brazil mainly in marshy districts, where it supports Mr. Hutchinson's theory by attacking principally the fish-eating part of the population. Thus it is very prevalent in Para and in parts of Maranhao. Even to allow whale's flesh to form a large part of a person's food would seem to be enough to produce leprosy, as is shown by the disastrous effects of such a diet on the Itacaripa islanders. To avoid getting leprosy in Brazil, then, it would be as well to abstain even from the appearance of fish. As regards treatment, the essential thing is to improve the dietetic and hygienic conditions of the people; isolation the author regards as brutal and unnecessary.

The greater part of the book is taken up with the opinions of various authorities on the points at issue. The account of the author's own work occupies but a few pages, and nearly as much space is devoted to a spirited denunciation of bacteriologists in general and Hansen in particular. So vigorously does he inveigh against them that in one place he has to check himself with the reminder that the "study of leprosy requires calmness, prudence, and meditation."

A vigorous opposition is as useful in science as in politics, but in the former its duty is not merely to oppose but to oppose in an unbiased spirit. While we admire Dr. de Magalhães as a man who is not afraid of being in a small minority, it cannot be denied that the partisan spirit in which he writes detracts seriously from the value of his work.

---

SWANSEA WORKHOUSE INFIRMARY.—At the meeting of the Swansea Board of Guardians held on Sept. 10th it was decided to appoint a resident medical officer to the Workhouse Infirmary. Mr. D. H. Thomas, the visiting surgeon, having resigned the appointment, will be granted a superannuation allowance.

# Analytical Records

FROM

# THE LANCET LABORATORY.

(1) SOLOID STAIN METHYL VIOLET; (2) TABLOID BISMUTH RHUBARB, AND SODA; AND (3) ENULE PREDIGESTED MEAT AND MILK SUPPOSITORIES.

(BURROUGHS WELLCOME AND CO., SNOW HILL BUILDINGS, LONDON, E.C.)

WE have already pointed out the convenience of "soloid" microscopic stains. They afford a ready means of preparing a staining solution for microscopic work in a short time and possess the advantage that they need not be used until required, and of course the dye in the solid state, as in the "soloid," is permanent, while the liquid stains are liable to changes. A recent important addition to the list is the methyl violet soloids containing 0·1 gramme of the dye. Standard solutions can therefore easily be prepared with the "soloid" methyl violet. As is well known, methyl violet is a useful and quick stain for various micro-organisms and notably for the diphtheria bacillus. The following formula of ingredients now embodied in a tabloid is of well-known value in certain forms of gastric disorder: bismuth subnitrate, three grains; powdered rhubarb, one grain; and bicarbonate of soda, two grains. The tabloid on moistening readily disintegrates, so that for the purpose of administration the drugs contained in it may be regarded as being taken in the form of powder. We have also received specimens of rectal suppositories containing predigested meat and predigested milk respectively which are of a size suitable for administration to children. They are of a shape which renders the expulsion of the suppository after its greatest diameter has been passed impossible. This particular brand is distinguished by the word "enule."

SHREDDED WHEAT BISCUIT.

(THE CEREAL MACHINE CO., 57 TO 63, JACKSON-STREET, WORCESTER, MASS., U.S.A., AND 6 AND 8, EASTCHEAP, LONDON, E.C.)

It is surely enough to know that this preparation is wheat, whole wheat, and nothing but wheat, to be able authoritatively to speak of it in terms of praise. There is a strong tendency nowadays to submit natural foods to some process of preparation, a course which too often leads to the loss of a very serious proportion of the valuable food constituent of the original product. According to our analysis this is not so with the shredded wheat biscuit, besides which all that is done in its preparation is to make the whole wheat berry elastic by steam after it is thoroughly cleansed, and then to tease it out, so to speak, into a homogeneous mass of shreds. In appearance the shredded wheat biscuit may be said to resemble a miniature wicker-basket. It is a very palatable and crisp biscuit containing the entire constituents of wheat, which, of course, include the germ. Our analysis gave the following results: moisture, 10·35 per cent.; proteids, 12·84 per cent.; mineral matter, 1·50 per cent.; fat, 0·80 per cent.; soluble carbohydrates, 38·40 per cent.; and insoluble carbohydrates with fibre, 36·11 per cent. We have not examined a preparation of wheat in which the total amount of soluble matters is so high as is shown in the foregoing analysis of shredded wheat biscuit. And this large proportion of soluble carbohydrates is due chiefly to dextrinised starch. The clear water extract of the biscuit gives a heavy brown red colouration with iodine instead of blue, as would be the case with soluble starch. It is evident, therefore, that the process of preparation not only moulds the biscuit into a pleasing texture and form, but renders it a very digestible article of diet as well. A comparison of the foregoing analysis with the analysis

of entire wheat shows that the proportion of constituents is the same, but more than a third of these constituents by weight is converted into a more digestible state. The biscuit may be used with distinct advantage as a substitute for bread and a great many attractive dishes can be prepared with it. Though it contains the entire wheat it is free from irritating husk. Dietetically it is superior to the average white bread. Owing to the fact that the carbohydrates of the original wheat are largely broken down in the method of manufacture it is very suitable for invalids. The biscuit keeps well, apparently neither absorbing moisture nor losing it. In view of these results we regard the shredded wheat biscuit as a very important addition to our daily foods. It represents an unimpoverished natural product and on this account claims our commendation.

### CAFOLIN LIQUID COFFEE.

(THE CAFOLIN CO., 20, EASTCHEAP, E.C.)

We believe this to be a genuine coffee extract concentrated by approved methods. According to our analysis it contains just over 1 per cent. of caffeine. A good infusion of coffee (one of coffee to ten parts of water), according to our analytical experience, contains on an average 0·11 per cent. of caffeine, so that this "liquid" diluted ten times would yield a beverage of the same strength as good coffee infusion as regards the amount of alkaloid. The diluted liquid coffee does not, however, contain any important quantity of the other principles of freshly roasted coffee which are represented chiefly in oils and certain aromatic substances. The liquid has a tendency to deposit its caffeine associated with tannin. The liquid yields a palatable beverage of pleasant coffee flavour possessing the stimulating properties referable to caffeine in the same degree as a well-made infusion of coffee, judging from the proportion of alkaloid present.

### (1) GLOBENARIS WATER; AND (2) MEAT PREPARATIONS.

(COOPER AND CO., 80, GLOUCESTER-ROAD, SOUTH KENSINGTON, LONDON, S.W.)

It is curious how the presence of an excess of oxygen in ordinary carbonated water modifies its taste. The sharpness of ordinary aerated water seems to yield in favour of a smoother or "rounder" flavour. Of course, oxygen is not dissolved by water with the same facility as is carbonic acid gas. Nevertheless, we found in "globenaris" water just over 5·26 per cent. of oxygen in the escaping gases. The water proved to be of praiseworthy purity, barely a trace of residue being obtained on its evaporation, nor was there any evidence of metallic contamination on testing carefully with the well-known delicate reagents. It is exceedingly difficult to prepare distilled water without some form of contamination, however slight, creeping in, and when it contains carbonic acid and oxygen under pressure the difficulty is enormously increased. We have found that oxycarbonated water attacks metals such as copper and zinc much in the same way as do the mineral acids. By first oxydising the metal an oxide is formed which soon gives place to a soluble supercarbonate. Messrs. Cooper and Co. have taken immense pains to produce aerated waters of remarkable purity and have established special machinery for this purpose which we have had the opportunity of inspecting. Such attempts deserve success and we are glad to be able to record that this success has been obtained judging from the satisfactory results of our analyses of the products. It need hardly be added that after taking these special precautions with the machinery every endeavour is made to provide against the contamination of the water in syphons. In these vessels pure fittings are used, the outlet tube of the syphon being porcelain-lined. In addition to pure plain aerated water charged both with oxygen and carbonic acid Messrs. Cooper and Co. also prepare medicated oxycarbonated waters containing, for example, lycetol, lysidine, phenocoll, and piperazine. Oxycarbonated water affords a very agreeable way of administering these drugs which are known to be of value chiefly in conditions in which excess of uric acid is a feature. Amongst other preparations submitted to us by this firm was a specimen of meat juice which on analysis gave the following results: moisture, 61·00 per cent.; mineral matter, 6·91 per cent.; and organic matter, 32·09 per cent. The total nitrogen was 3·72 per cent. which proved to be distributed as follows: nitrogen in insoluble albumin, 0·284; in acetic acid coagulum, 0·180; in peptone and albumose, 2·092; and in meat bases, 1·164. The juice is therefore a true nutritive as well as stimulant. We examined also a beef essence and a chicken essence, both of which are jellies containing, as our examination showed, a desirable proportion of the nutrient matters of beef and chicken respectively. Moreover, both jellies possessed a delicate and palatable flavour.

### (1) KALSBECK TABLE WATER; AND (2) KALSBECK TABLE WATER CUM LITHIA.

(REID AND DONALD, PERTH.)

Both aerated waters proved to be free from the common impurities of waters of their class. They were bright and sparkling and yielded a clean mineral residue on evaporation. The table water contained 16 grains of mineral salts per 12-ounce bottle, consisting chiefly of the carbonates of lime and the alkaline carbonates. The lithia water yielded on evaporation just over 23 grains of mineral salts; this increase may broadly be taken as due to the carbonate of lithium present. The water gave a well-marked reaction for lithium when examined by means of the spectroscope. The waters were free from organic matters. In accordance with these results we regard them as approaching a satisfactory standard of purity, while the lithia water has an added value on account of the lithia present which may in this way be administered very agreeably.

### FLORAL HAIR DOUCHE.

(SOUTHALL BROTHERS AND BARCLAY, LOWER PRIORY, BIRMINGHAM.)

This is a very pleasant spirituous preparation containing certain ingredients which are admittedly beneficial when applied in this form to the hair. It is practically a dry preparation—that is, contains no water—so that its application produces no stickiness and leaves the hair clean and dry and with a generally agreeable sensation on the scalp. From a consideration of the formula it would seem that this douche is a good tonic application for the hair. It is distinctly antiseptic and contains no irritating or injurious substances. On account of its wholesome influence on the scalp it minimises the tendency to dandruff.

### SOLEX IPECACUANHÆ.

(FLETCHER, FLETCHER, AND CO., HOLLOWAY, LONDON, N.)

Solex ipecacuanhæ is practically a standard ipecacuanha preparation by means of which ipecacuanhæ wine may readily be prepared. The preparation is neutral and miscible, containing 0·8 gramme of total alkaloid in 100 cubic centimetres, and the inert extractive matters are as far as possible eliminated. The preparation mixed with seven volumes of sherry forms the vinum ipecacuanhæ B.P., 1898. The result is after some time a slightly turbid liquid, which may be rendered, however, quite bright by filtration without affecting its active therapeutic strength. We are glad to record this important improvement, inasmuch as the ordinary liquid extract of ipecacuanhæ is one of the most unsatisfactory preparations of the pharmacopœia. Solex ipecacuanhæ, on the contrary, is a standard preparation yielding an ipecacuanha wine of definite strength and therapeutical efficiency on diluting it with sherry in the proportions indicated.

# THE LANCET.

*LONDON: SATURDAY, SEPTEMBER 22, 1900.*

IT would be a libel on the wealthy men of Great Britain, who are yearly becoming wealthier in spite of wars and Chancellors of the Exchequer, to regard them as indifferent to the best voluntary use of their superfluous means and especially to the enormous amount of good that may be done by the endowment of medical science and research. The voluntary hospitals of this country are sustained in their blessed and benevolent work by a deeper personal sympathy with the sick poor than exists in most countries where such institutions are maintained by enforced rates or taxes. If we could convince the generous wealthy that the cause of medical science is the cause of the poor and that the cultivation of this science would help the work of hospitals as well as minister to the prevention and cure of disease among all classes, we should procure such bequests and legacies, not to say gifts during life, from benevolent men as would make Britain what Britain ought to be as the country of JENNER and of LISTER—the leader in those investigations which go to the very root and source of disease with a view to its extinction and suppression as well as its cure. There are indications that if such countries as ours are to preserve their power and their rule in the world they must not rely so much as heretofore on the tendency to multiplication in the race which so far has well supplied our wants. We must husband the lives that we have in all stages of their existence and oppose with all the resources of reason and of law whatever can be demonstrated to be the cause of disease and premature sickness and death. It is only this demonstration that needs to be forthcoming to induce generous citizens to make endowments that might alter the whole outlook of many individual lives and of particular races. It is only the nature of the problems to be investigated that hinders. This is so abstruse and complicated and so much out of the track of common observation that it seems incomprehensible and uninteresting to the lay mind. Mr. ANDREW CARNEGIE, whose colossal wealth, if well used in this way, might without any noticeable impoverishment of himself be equal to the elimination of two or three of the great causes of death that are the despair of our large city communities, draws a distinction, especially with reference to our own country, in this respect between the lay mind and the professional mind. He speaks of the splendid legacy of Sir ERASMUS WILSON to the Royal College of Surgeons of England and looks in vain for any similar liberality in the aristocratic classes of Great Britain. This comparison, or contrast, is only part of a larger contrast which Mr. CARNEGIE in his "Triumphant Democracy" draws between the alleged selfishness of the aristocratic classes and the liberality of the Republic of which he is so justly proud He is more right when he suggests that the contrast is due to personal differences in the intelligent apprehension of the questions and problems to be studied rather than to the nature of the Government under which we live. He is naturally proud of the splendid educational institutions of the United States bestowed by individuals on the Republic—the Johns Hopkins University, the Cornell University, the Vanderbilt University, the Packer Institute, the Vassar College, the Wellesley College, the Smith College, the Bryn Mawr College, and the Stevens Institute, the Johns Hopkins University alone having cost £1,000,000. Mr. CARNEGIE himself has given $50,000 to build a laboratory in Belle Vue College. As we have said, the researches and investigations needed refer to problems of great complexity and are naturally understood better by the medical man than by the rich layman, whether aristocratic or democratic. Our belief is that we have only to make the nature and claims of these problems a little more clear to our wealthy compatriots to get from them as generous gifts as those which have founded and now maintain our voluntary hospitals. It was THOMAS GUY, himself a rich man, who built and endowed a hospital which for over 100 years ministered to 400 of the poor of south London, and the generosity of his successors has enabled the hospital to do a still larger service to the poor.

There is every reason to wish that wealth should be devoted to medical science for its benevolence to man and beast, for both have promise of untold benefits from its researches. We have an object lesson at the present moment in Great Britain. In Glasgow a few cases of plague have appeared. Where is the panic that such an event would have occasioned a hundred or even fifty years ago? It does not exist. Why? Because medical science has defined the danger and the way to deal with it. In several quarters, even in this aristocratic country, many signs are appearing of the intelligent application of wealth in a benevolent way to medical science. Witness the munificent gift of Lord IVEAGH to the Jenner Institute of Preventive Medicine. Only last week we noticed the gift to Guy's Hospital of £5000, the interest of which is to be used "to increase and spread the knowledge of the means of preventing and treating disease." The gift is from "A Friend of the Hospital" and tends to indicate that the same sympathy which provides hospitals will soon endow research and that such an intelligent use of wealth will be most natural in a country which has endowed colleges, universities, and hospitals for centuries back. The more Mr. CARNEGIE revolves this subject in his mind the more difficult will he find it to know for which mercy to be most thankful—that he was born a Scot or that he was nurtured an American.

THE paper issued by the War Office last week containing the proceedings of the court of inquiry into the treatment of the British prisoners of war at Pretoria, with a covering despatch from Lord ROBERTS to the Secretary of State for War, is by no means pleasant reading. It discloses a very discreditable state of things on the part of the late Transvaal Government. It also contains a very emphatic expression of opinion on the part of the Field Marshal in regard to a member of the medical profession. After speaking in deservedly

appreciative terms of the efforts made by Dr. P. H. HAYLETT and Dr. R. VON GERNET to ameliorate the condition of their patients in the hospitals at Racecourse and Waterval and of the timely aid and effective coöperation rendered by some gentlemen resident in the neighbourhood, Lord ROBERTS goes on to say: "On the other hand, it would be difficult to condemn too strongly the conduct of Dr. H. P. VEALE, M.B. Cambridge, whose heartlessness in ignoring the disgraceful treatment of the sick prisoners and the remonstrances addressed to him by the medical officers in immediate charge of them calls for the severest reprobation." We have thought it right to quote the exact words used by the Field Marshal because they serve to indicate the feeling of indignation which a perusal of the whole of the documentary evidence evidently aroused in the mind of Lord ROBERTS, who is universally recognised as a just and humane man.

It is necessary, however, to remark that the War Office document is incomplete in that many of the letters referred to in the text are not published, and it is only fair to Dr. VEALE to state that in his examination before the court of inquiry he said that he was one of the three medical members of the Transvaal branch of the Geneva Red Cross Society; that he had nothing to do with the sanitary arrangements of the prisoners of war at the Racecourse, although he allowed that it would be his duty as medical officer attending the sick to represent and try to remedy anything which he found prejudicial to health, and this he did; that he disclaimed all responsibility for the medical and sanitary arrangements for the prisoners of war at Waterval; and that he denied having received most of the letters alleged to have been addressed to him by Dr. HAYLETT representing the grievous condition of the hospitals and their occupants. We propose to defer any comment of our own on Dr. VEALE'S conduct until sufficient time has been given to permit of his making public what he has to say in justification or explanation of his action.

Whilst we are upon this unpleasant subject we may add that we are glad to believe that there are not many clergymen in the Church of England like the Rev. J. GODFREY who under colour of consideration of his duty to the Transvaal Government and in order to gratify his "desire to maintain the honour due to his position" discontinued the regular ministrations of the services of the Church because a prisoner, and he a non-combatant, had escaped. We commend to the notice of the Rev. J. GODFREY a study of the life of Father THOMAS of Algarve who refused his ransom in order to minister to the Portuguese prisoners of the Moors in the dungeons of Al Araish.

As regards the general question of the treatment of the British prisoners of war—the bad quality and insufficient quantity of the rations, the neglect of all sanitation, the treatment of the colonial corps prisoners, and so forth—we need not dwell upon a subject which has been already so fully discussed in the daily journals. Happily that is all over and a thing of the past now.

---

THE *New York Medical Record* of August 11th contains a full abstract of an address on American Medicine, delivered at the International Medical Congress in Paris by Dr. JACOBI of New York, which gives a very interesting account of the development of the profession and of medical science and literature in the United States. There are parts of the address with regard to which opinions may differ. We observe that our contemporary in its issue of August 25th takes exception to Dr. JACOBI'S criticisms on American medical journalism, and it must be admitted that Dr. JACOBI is very candid in the denunciation of hundreds of medical journals which, according to him, represent rather "the growing commercialism" of the century than any ardent desire to advance medical science or medical literature. He declares that there are 300 such journals and that neither medical science nor medical ethics would suffer if the number were reduced to 50. Such a great number of journals and the competition implied thereby Dr. JACOBI thinks to be inconsistent with the independence of the editors and with high aims on the part of the proprietors. Our contemporary resents such aspersions with some warmth, and if we thought that Dr. JACOBI meant his criticism to be applied indiscriminately to American journalism we should regard the resentment as reasonable. But we must take his arithmetical and other facts into consideration. His figures are certainly startling apart from his positive statement, which most of us in Europe can confirm, that many journals seem to exist to puff proprietary articles. Perhaps he is wrong in regarding them as in any proper sense medical journals. Certainly no such number of real and honest journals could be supported even by the large numbers of the American profession. For the class of papers which he condemns no censure is too severe and it seems to us that all honest medical journals should feel grateful to an independent critic for plain speaking on the subject. The one necessary thing for the respectability of journalism, professional or otherwise, is independence. It would be unreasonable to expect proprietors to be above all considerations of profit, but it will be a bad day for scientific journalism if an independent medical critic cannot say what he thinks of the fitness of the journals of the profession to advance its science and its dignity.

Dr. JACOBI is almost equally severe on the number of medical societies in America. In Colonial times there were two; in 1876 nearly every State in the Union had its medical society, and most counties in each State have their own medical society. All the state societies are represented in the American Medical Association, save one. The exception is a great one—that of the State of New York. This State is excluded, and it is instructive to notice that the reason for its exclusion is an ethical one. There is no central authority in the United States vested with any legal disciplinary power over members of the profession as is the case to a certain extent with the medical authorities and the General Medical Council in the United Kingdom. The disciplinary power in the United States lies in the societies, and chiefly in the American Medical Association in which all the State societies are represented. The State societies exercise their disciplinary power by refusing membership to medical men who take out patents for medicines, or who advertise themselves or allow themselves to be advertised by others; and the American Medical Association has its code of ethics based, we are proud to say, on the classical work of PERCIVAL, our own great

medical moralist. It expects all associated State societies to fall into line with the requirements of this code and, failing to do so, it excludes them from representation or expels them as in a significant case in 1882. The question of holding relations with homœopaths arose in that year. There was the same universal feeling against such relations as obtains in this and in all European countries. It obtains, also, in the United States, but in the New York State Society a special point was raised and contended for strongly. This Society admitted the general impossibility and incongruity of consultations between regular practitioners and those committed to the dogmas of HAHNEMANN, but it was argued that in some cases it would be inhuman to refuse a consultation and the Society modified their law to meet exceptional cases and cases of emergency. For this modification, of which Dr. JACOBI speaks approvingly, the State of New York was expelled from representation in the American Medical Association. The American Medical Association has no legal relation to the legislature of the United States as the State societies have. It is nevertheless a powerful body, more powerful in some respects for being voluntary and unrestrained by law, and is capable, as we have seen, of making its views felt by the societies of individual States. The action of the association in this particular question was the more resolute and striking inasmuch as homœopathic and eclectic practitioners in the States are legally recognised as much as regular practitioners, but this is only an additional reason for regular practitioners in voluntary associations emphasising the difference between them and their fanatical competitors.

The peculiar legal position of the profession in the United States is well shown by Dr. JACOBI and must be remembered by all who wish to judge fairly the difficulties in the way of medical practitioners and medical teachers there. Of late years, with an enormous advance in medical education and in medical practice, there has been actual retrogression on the part of the States in respect of medical legislation. In 1840 the legislatures of nearly all the States had laws for protection of the citizens from quacks. Between 1840 and 1850 most of these laws were repealed or not enforced out of deference to unlicensed practitioners. The power to confer degrees rests in the different States on the most various conditions of law. In New York and Pennsylvania the conditions are satisfactory, but in Illinois, where so much has been done by medical teachers to improve education, legislation like that of New York has been defeated. In Ohio and Nebraska the statutes require only the nominal endowment of $5000 for the creation of a degree-conferring institution. In other States and Territories any body of men may form an educational corporation with power to confer degrees. So wide is the difference of standard of medical education and qualification that it is difficult for the different States of the Union to arrange for reciprocity of medical practice between their graduates.

Such are the disadvantages of the medical profession in a new country having democratic institutions based on an exaggerated view of the rights of the individual in regions where he can have no rights not acquired by study and special knowledge. But such disadvantages can only raise our esteem for those who, prevailing over all difficulties, have brought the medical profession to a pitch of efficiency, alike in the region of research and the domain of practice, which compares favourably with the standard of any European country. The number and competition of the schools, of which in 1899 there were 156, with 24,119 students, having a very inadequate check on their degree-conferring powers, only makes us wonder the more that within recent years it has been possible in many States to extend the medical curriculum to three or four years, and to report through societies and journals an amount of good work which implies a very high standard of education in some quarters and a very high pitch of medical and surgical ability diffused throughout the enormous area of the United States. Dr. JACOBI, while severe enough in his criticisms on medical journals and medical societies, leaves us in no doubt that he is proud of his *confrères* and not altogether prepared to condemn that democratic constitution which has created medical libraries and medical laboratories that are the envy of older countries.

# Annotations.

"Ne quid nimis."

## THE WORK OF THE GOVERNMENT LABORATORY.

THE work of the Government Laboratory grows apace and increases in interest every year. There can be little doubt that the appointment of Dr. Thorpe a few years ago in succession to Dr. (now Sir James) Bell led to a considerable amount of reorganisation of this important department. The annual reports at any rate show that the operations conducted in the Government Laboratory have been reduced to something like a system. As a result of this improvement in the equipment of the department together with the erection of new and modern constructed laboratories in Clement's Inn-passage, the Government has called into greater requisition the services of its laboratory department. The old Somerset House laboratory was primarily instituted for the purpose of controlling Inland Revenue regulations which referred chiefly to beer and spirits. The work now not only relates to Customs and Excise but to the examination of foods, water-supplies, sewage effluents, Government office supplies, and a number of miscellaneous articles with which the various Government departments come into contact. Further than this the principal of the laboratory practically occupies the position of a consultant and adviser to the Government, a *rôle* which cannot be fulfilled without the institution of some amount of original research. Dr. Thorpe was called upon, for example, to inquire into the use of lead compounds in pottery manufacture, and this involved the making of a number of experiments on the composition of "frits" which could be regarded as least likely to produce lead poisoning. The inquiry, as we know, has led to excellent results which have stimulated the pottery industry to abandon the use of raw lead and in some cases to discard the use of lead altogether for glazing purposes. Again, Dr. Thorpe's assistance has been in request in an inquiry into the composition of defective steel rails, and other subjects have been referred to him relating to the defects of boiler-plates, shafting, and cranks in connexion with accidents under investigation by the Board of Trade. The work of the principal of the laboratory has been considerably increased also by the fact that he has been appointed by the Local Government Board, in succession to the late Sir Edward Frankland, to undertake the analyses of the London water-supplies. In our opinion this

department should have been perfectly distinct from the work originally undertaken in the Somerset House Laboratory. It is to be observed, however, that a special room has been fitted up for the purpose of making the analysis of the London water-supplies. Still it is evident from the present report that Dr. Thorpe's hands are quite full and we should have thought that this important department of public work would have been placed in the hands of a person who could devote his whole time to the subject. As we have already pointed out the reports on the water-supply are much belated and are generally issued two months after the taking of the samples. We do not gather whether the additional space granted for the analysis of the London water-supplies includes a bacteriological laboratory. Since filters and disinfectants are also examined in the Government laboratory we presume that bacteriological tests are conducted there, though in the instances given in the present report we do not find any details as to how the antiseptic value of rejected and accepted disinfectants was arrived at or as to exactly why a certain filter was found to be satisfactory and others unsatisfactory. We are glad to see that the relations between the public analysts and the Government Laboratory authorities continue to improve. In the majority of cases the findings of the public analyst as to adulteration of milk and butter and other things have been upheld. We note, also, with satisfaction that Dr. Thorpe has conferred with representatives of the Society of Public Analysts as to the analytical data to be regarded as criteria in deciding whether or not butter contains foreign fats. The laboratory officials have also been busy in examining samples of imported beer for the presence of preservatives for the information of the departmental committee now inquiring into that subject in its relation to the purity of food. Beer continues to be diluted, but the practice is almost entirely confined to London. Of 95 samples of tobacco taken from manufacturers and dealers 20 were found to be adulterated with liquorice or glycerine. A curious case of spontaneous ignition was investigated in which it was shown that zinc dust sent through the post in a paper wrapper had been the cause of the phenomenon. The report teems with interesting facts in connexion with most kinds of fraud and adulteration as well as also with many important points relative to home industries and those which involve risk to those engaged therein. Instead of the mere digests of these facts in an official document of only 17 pages we should like to suggest that the whole of the results obtained in the Government Laboratory during the official year should in the future be embodied in a blue-book much in principle and in scope like that issued annually by the medical officer of health of the Local Government Board.

## THE SOUTH AFRICAN COMMISSION.

WE must, of course, await the publication of the report of the South African Commission at the end of its inquiry before expressing any definite opinion in regard to the subjects under investigation. There does not seem to be any valid reason, however, against our calling attention, in the meantime, to the very important evidence given by Lord Roberts which has been supplemented by that of his private secretary, Lord Stanley, and followed by the testimony of Lord Kitchener. As chief of the staff Lord Kitchener was probably better acquainted with the difficulties and details of the transport service than any other officer at the seat of war. It is naturally very satisfactory to us to find from the brief reports which have appeared of their evidence that we were amply justified in the position which we took up from the first and to which we have throughout adhered. That is, however, a very secondary and insignificant matter as compared with the general sense of relief which promptly followed the perusal of Lord Roberts's evidence. It was not so much with the truth or otherwise of Mr. Burdett-Coutts's allegations that most people concerned themselves as it was with the suggestion that all the suffering and hardship which he so vividly described were attributable to want of foresight, negligence, and bad management. It was this that made his allegations so distressing to people in this country. The assurance of Lord Roberts that owing to the difficulties of transport in connexion with his advance and the nature of the country they were unavoidable has naturally given rise to an immense sense of relief. We know now that, in the opinion of Lord Roberts, the campaign had been an extraordinarily difficult one from the hospital point of view and that the Royal Army Medical Corps, assisted by the civilian surgeons, as he emphatically stated, had met the difficulties magnificently. We need not discuss the facts detailed by Lord Roberts in his evidence in connexion with the insufficiency of the railway and other methods of transport at his disposal, but we may make a remark in passing that we are glad to have from the first pressed for the appointment on the Commission of some one or more managers of our big railway lines, to whom the facts and figures addressed by Lord Roberts cannot fail to prove of great value when the time comes for drawing up the report. We may add that Lord Kitchener's evidence agreed with that given by Lord Roberts. He said that the difficulties of transport were very great and constituted a serious problem throughout. It had been largely requisite to subordinate everything to the necessity of a rapid advance. The hospital appliances carried on Lord Roberts's advance amounted to 1680 tons and it was impossible to take more equipment or *personnel*. Lord Kitchener acknowledged that doubtless a good deal of suffering was undergone, but this was not due to neglect by the medical officers or to the equipment of the field hospitals. The experience gained in South Africa will not, we trust, prove barren of good results but lead to all needful improvements in our military and hospital systems in the field. Altogether apart from the report of the Commission there will remain subjects for serious consideration. As Lord Roberts suggested, it will no doubt be very advisable when the war is over that there shall be a departmental inquiry into the questions which have been raised in connexion with the Royal Army Medical Corps in time of war.

## INDUSTRIAL TRAINING OF GIRLS UNDER THE POOR-LAW.

A REPORT has been prepared by Miss Stansfeld, assistant inspector to the Local Government Board, on the Industrial Training of Girls in the Metropolitan District Schools, presenting the objects it is desired to attain and the methods of training adopted in the various schools. As is so frequently the case with educational reports, the teaching provided is described with but few indications of the mental and physical characteristics of the children and their special needs; thus material is lacking for the formation of a sound opinion as to what their training for industrial occupation should be. We dwell upon this point because much confusion exists between educational training planned to evolve the mental powers and character of the child and technical teaching in preparation for the work of adult life and self-support. Technical instruction is a poor substitute for educational labour spent in building up and evolving mental ability during early years. The report says: "The effects of neglect and heredity on mind and body are often only too apparent, and, even with the more active and intelligent children, it requires, in some cases, two or three years' existence in the brighter and healthier atmosphere of the school, before the influence of

previous surroundings can be finally thrown off; nor is this all, the pick of the Poor-law children are, as a rule, boarded out, and the failures of that system are returned to the workhouses and find their way to the schools. The presence of 'ins and outs' and the admission of children of 11 years old and upwards in a state of almost complete ignorance, seriously affect the administration of the schools." It is to a careful study of the scientific principles of training, founded on observation of the special children to be educated, that we look for advancement in results; also for some definite plan of action in place of vacillation and oscillation of opinion between methods of school training and technical instruction for the purpose of fitting the children for positions in industrial life at an early age. Miss Stansfeld says that the kindergarten should be universally, adopted; signs of greater alertness and intelligence among the infants may be observed in those schools where the kindergarten system is in vogue. We may venture to ask is there any universal system that it is wise to adopt, or, indeed, any one method including all the necessities for the training of children? The kindergarten system is very good, but is often employed with too little adaptation to individual children in evolving their brain power and removing brain faults, unless conducted by teachers well trained to observe the points that demand special attention. Contrary to the opinion of many representative guardians Miss Stansfeld advocates the grouping of girls after 14 years of age in associated or block-system schools so that a period of definite training for domestic service may be commenced, adding that in many instances the "mother of a cottage home" is wanting in natural qualifications and the experience necessary for imparting good domestic habits. These considerations naturally point to the great want of a model home or training college where probationers may be received for one or two years before appointment to the responsible care of children, and where they may learn some of the practical points of child management as well as laundry, cooking, and other domestic duties. It is in accord with experience that children need general education up to 12 or 13 years of age, and that technical or domestic training is better acquired after such preparation, while all persons engaged in the care of children themselves need training for such duties.

## THE FEVERS OF INDIA AND THEIR DIAGNOSIS BY MEANS OF EXAMINATION OF THE BLOOD.

THE medical practitioner in India early discovers that typical agues and remittents are not the commonest fevers which he is called upon to treat—they are, in fact, in most parts of India of comparatively rare occurrence—but he meets with innumerable cases of fever of a more or less irregular, continued type, generally with a morning remission of about one degree and a duration of anything from one day to six or eight months. With these fevers there is but little constitutional disturbance, and quinine, and in fact all drugs, are of but little if any benefit. Some recent writers have attempted to differentiate certain classes among these fevers on a basis chiefly of their duration, but it is easy to show a series with every gradation between the limits named and the introduction of new names without sufficient distinction only makes confusion more confounded. Among Europeans that scourge of hot countries, enteric fever, is probably now in most typical cases well recognised, but it may well be that some of these anomalous fevers are clinically mild cases of enteric fever and as virulent as the worst for spreading the infection. More knowledge on this point would be of the greatest value in tracing the means of spread of this disease which has up to the present admittedly baffled all attempts to elucidate it. Further, now that we have some clue to the method of transference from case to case of the malarial parasite by the agency of certain mosquitoes, the further elucidation of this imperatively demands a more accurate knowledge of what fevers are and what are not caused by this parasite. Again, some of these fevers may well be due to the cause, whether physical or microbic, of heatstroke, while some bear a very close resemblance clinically to Mediterranean fever. Now, by the microscopic examination of the blood, we have at our disposal a means of deciding with considerable certainty whether a certain fever is due to one of these three causes and it appears to be only from want of opportunity that more use is not made of the vast amount of clinical material available in India. When we consider that among the British troops alone nearly half the deaths and invaliding and nearly a third of the total sickness are due to these causes the importance of the subject can hardly be overrated. Most of the medical practitioners in India are Government servants and can hardly be expected to carry out this work entirely in their own time and at their own expense, and we would urge upon the authorities their duty to provide the necessary apparatus and opportunity to allow of an examination of the blood being made at least in all large hospitals. There are already many medical officers fully capable of carrying out this work and opportunity would speedily produce more.

## POLLUTION OF SEA-WATER BY SEWAGE.

AT the British Association in Bradford, Dr. E. A. Letts, Professor of Chemistry, Queen's College, Belfast, and Mr. John Hawthorne, B.A., of Queen's College, Belfast, communicated a paper on Sept. 8th, in the Chemical Section, on the Seaweed Ulva Latissima and its Relation to the Pollution of Sea-water by Sewage. For a number of years past a very serious nuisance has arisen from the sloblands of the upper reaches of Belfast Lough during the summer months, the stench at low tide being quite overpowering, and the air heavily charged with sulphuretted hydrogen. In the northern portions of Dublin Bay a precisely similar nuisance, though not of the same magnitude, also arises from the sloblands. The nuisance is caused by deposits of the green seaweed called "ulva latissima" or "sea-lettuce" ("sleech" locally), which in the two localities mentioned grows in abundance and during high winds or gales is washed ashore. In Belfast Lough the quantity thus deposited is enormous, forming banks which are often several feet thick, and which extend for miles along the coast. Once deposited these layers of seaweed often remain more or less stationary for months in the shallow bays or pools of the neighbourhood, and in warm weather rapid putrefaction occurs and a perfectly intolerable stench arises which is perceptible over a wide area and seriously affects not only the comfort of the inhabitants of the district but also the value of their property. An extended laboratory investigation has shown that when the seaweed ferments hydrogen and carbonic anhydride are first evolved in about equal volumes and fatty acids are produced. Propionic acid is the chief of these fatty acids; butyric acid is also formed and probably acetic acid in addition. In a later stage of the fermentation sulphides are also formed, probably by reduction of sulphates present in sea-water, and the seaweed blackens from formation of ferrous sulphide, and this latter disengages sulphuretted hydrogen by the action of the fatty acids, whence the nuisance. The evidence at present collected as to the organisms concerned in the putrefactive process points to there being two chief species—(1) a spore-forming bacillus which apparently infects the seaweed and causes the production of fatty acids from its tissues; and (2) a micro-organism probably derived

from the mud of the shore which gives rise to the formation of sulphides by a later fermentative process. The evidence tending to prove that the occurrence of the seaweed in quantity in any locality is associated with sewage pollution is of three kinds:—1. The composition of its tissues, the amount of nitrogen it contains being far in excess of any other seaweed of which analyses are recorded. It contains over 6 per cent. of nitrogen. 2. Assimilation experiments. A frond of the seaweed was placed in various mixtures in succession—(*a*) of polluted sea-water; (*b*) polluted sea-water, plus sewage; (*c*) polluted sea-water with sewage and ammonium salt; and (*d*) sea-water, plus nitrates. By determination of free and albuminoid ammonia and nitrates in these mixtures before and after the seaweed had been in contact with them the power of assimilating nitrogen which the weed possesses was found to be remarkably high. During these experiments the weed remained in perfect health and is still growing nine months since the commencement of the experiments. 3. The localities where ulva latissima abounds and from which it is virtually absent. It is in abundance in Belfast Lough, but is entirely absent from the neighbouring Strangford Lough, which is similiar in area and in many other respects to Belfast Lough, but differs from it in not being extensively polluted by sewage. In Dublin Bay the seaweed is found in abundance in the harbour, which is highly polluted, but not in the southern parts of the bay, which receive no sewage except near Kingstown, where a large sewage tank discharges at the ebb tide. There the weed occurs. The evidence which Dr. Letts and Mr. Hawthorne have collected tends to the conclusion that the occurrence of ulva latissima in quantity in a given locality is an indication of sewage contamination and there can be no doubt as to the power which the weed possesses of absorbing nitrogen compounds from polluted sea-water. While thus acting as scavenger it may itself give rise to a very extensive nuisance. These experiments are of great interest because they localise and explain the cause of the horrible odour existing on the shores of Belfast Lough. When the Belfast corporation got their last Bill passed they were obliged to introduce a clause binding them to purify their sewage, which empties into the lough, so as to remove the smell from its shores. They propose to do so by bacterial beds, but as they have made no experiments as to the effect of the effluents from these beds on this "ulva latissima" the smell may still exist as badly as ever. They should first see the effect of growing this seaweed in the effluent.

## RECOVERY FROM LEPROSY.

IN the June number of the *Polyclinic* Mr. Hutchinson relates a number of cases showing that recovery from leprosy is possible. He expressly guards himself against captious criticism by explaining that by recovery he means termination of the disease process, not removal of its effects. In one case shown by him at the Polyclinic the patient was a soldier who had served in India. The patient had had anæsthetic leprosy of the forearms and legs. The hands and feet were dusky from passive congestion and discoloured by the brown patches of leprosic erythema. A remarkable but not unprecedented fact was that he did not notice any patches until eight years after returning to England. The treatment, which was carried on for 10 years, consisted in the administration of small doses of arsenic, a liberal diet, and abstinence from fish. After 18 months the patches had disappeared. From that time there was slow restoration with absolute abeyance of symptoms. His hands became less dusky and numb. Now the patient can use his hands well and they show no conspicuous changes. They look flabby and the smaller muscles are somewhat wasted. There is permanent anæsthesia of the hands so that the patient often burns himself unconsciously. The feet are similarly affected in less degree. All evidences of active leprosy have now been absent for six years. In a second case a man was blind from leprosy and his hands were somewhat helpless from anæsthesia and muscular wasting. But he was florid and healthy looking and his skin showed no trace of tubercle or patch. For the last 10 years he had been free from aggressive symptoms. In former years leprosy was regarded as incurable, but of late cases of recovery have been observed. According to Mr. Hutchinson they have chiefly been observed in countries where leprosy is not endemic and in patients who migrated from the place where they acquired the disease and were therefore placed under different dietetic conditions. In 1879 Mr. Hutchinson published in the Transactions of the Royal Medical and Chirurgical Society the case of a woman who had returned from Barbadoes the subject of tuberculous leprosy. He never saw the leonine physiognomy more marked. After residing in England for some years she lost all traces of leprosy and with the exception that her hands were numb and crippled she remained quite well. She was enjoined to abstain from fish. Since then Mr. Hutchinson has seen many cases of lepers in whom all symptoms have ceased on returning to England. In America it has been noticed that a number of Norwegian lepers entirely lose their symptoms. In leper establishments in which fish has been an important article of diet little or nothing has been heard until lately of recoveries. Mr. Hutchinson considers that these facts support his contention that leprosy is due to the eating of raw fish—salted, dried, or decomposing.

## THE GOVERNMENT CINCHONA PLANTATION AND FACTORY IN BENGAL

THE official reports of Major D. Prain, I.M.S., superintendent of the Royal Botanic Garden, Calcutta, and of Cinchona Cultivation in Bengal, are interesting documents to botanists, horticulturists, and quinologists. The report of the Royal Botanic Garden, Calcutta, is for the year 1899–1900. Although the rainfall of the year was heavier than usual it did no harm to the foliage plants, ferns, and orchids, the show of which, we are told, was particularly fine. Plants of economic importance received a good deal of attention, especially rhea, a practical machine for extracting the fibre of which is said to have been invented. An investigation into the diseases to which sugar-cane is subject in Bengal is being conducted by Lieutenant A. T. Gage, I.M.S., curator of the Herbarium. The inquiry into the identity of living plants yielding Indian products of obscure origin was continued during the year with valuable results. A representative collection of the various mangoes cultivated in northern India and Bengal has been made on behalf of the Trinidad Government. As regards the report on the Government cinchona plantation and factory in Bengal the report is for the year 1898–99, from which we glean the following facts. The nursery beds of the Mungpoo Division were considerably injured by the low temperature which prevailed in January, 1899, and the mortality among the seedling plants was great. The result of the year's operations was that the total number of living plants (exclusive of the nursery stock) was 2,179,245. The crop of the year obtained from the trees uprooted in the Government plantations in Sikkim amounted to 236,098 lb. of dry bark. The bulk of the bark was of the quinine-producing sort, and with the exception of 1003¼ lb. supplied to medical depôts or sold to Government officers and to the public, the whole crop was, as usual, made over to the cinchona factory for manufacture into quinine and febrifuge. Besides the bark obtained from cropping, 131,615 lb. of bark were

purchased from private plantations in Sikkim and Southern India. The out-turn of the factory was 10,335 lb. of sulphate of quinine and 3921 lb. of cinchona febrifuge, against 10,149 lb. and 4075 lb. respectively in 1897–98. The decrease in the issues of sulphate of quinine is due to a diminished demand on the part of the medical depôts in the Bengal and Punjab commands, to the transfer to the Madras factory of the obligation to supply the North-Western Provinces with the drug, and to the falling off in the demand by Government officers and medical missions for distribution to the poor. The decrease of 404½ lb. in the issues of cinchona febrifuge is attributed to the fact that Government officers took smaller supplies than in the previous year. The stock of sulphate of quinine in hand at the close of the year was greater by 1569 lb. than it was at the close of the year 1897–98. The superintendent, Major D. Prain, I.M.S., and also Mr. R. Prantling, the deputy superintendent of the Cinchona Plantations, received the thanks of the Government of Bengal for their efficient management of the plantation and factory.

## THE CONCILIATION BOARD AND THE BRITISH MEDICAL ASSOCIATION.

IT seems as if the honours in respect of a Conciliation Board were to be equally divided between the General Medical Council and the Council of the British Medical Association. The General Medical Council has the honour of having done much to bring the Conciliation Board within the lines of medical politics. The Council of the British Medical Association has the honour of having with a stroke of the pen and at the fag end of an exhausting meeting dismissed the principle. One of the small general meetings of the Association could not have acted with more apparent irreverence towards a principle in which many sensible people see the solution of perplexing problems in general as well as medical politics. Perhaps there is some misunderstanding on the subject. The Council of the British Medical Association has still, we believe, a committee of experts on the subject. We shall patiently await their report before judging the action of the Council.

## EXPERIMENTAL STUDY OF CHILDREN.

THE annual reports of the United States Bureau of Education always contain some valuable scientific papers, either produced in America or compiled from materials collected in other countries, together with a general account of educational progress. We have before us a reprint from the report for 1897–98 in which Dr. MacDonald explains the methods he employs in the study of mental averages and inequalities. Different means of studying mental potentialities have been employed by observers. The clinical method consists in observing children by inspection of the development of each feature—the head, the height, and weight, &c., while brain activity and power are estimated by motor expression, response, and coördination; this method has led to practical results. The anthropometrical method and the use of instruments of precision for measurement and time reaction as employed by Mr. Francis Galton and many other observers have given us much accurate knowledge of facts concerning growth, but the results of summarisation do not appear to afford the desired information concerning mental ability and potentiality. A third method of study is by purely psychological inquiry, such as answers to written or oral questions and the recollection of adults of their experiences in childhood; such methods have been used in America by Dr. Stanley Hall, Professor Earl Barnes, and many others, and they have led to some knowledge of the character and methods of thought among children, while indirectly certain deficiencies in current child-literature and teaching have been clearly brought to light. The modes of procedure employed by different observers differ almost as much as the methods of study. Some inquirers examine all the children in each school selected; others look only to find children of a certain class, or note groups of children selected by the teachers. Dr. MacDonald's investigations are mainly conducted by the use of instruments for measurement of the body and of the sensitiveness of the surface to touch and pressure. His list of abnormal points for observation is curiously wanting in arrangement and classification, containing in succession "expression, hand balance, nutrition, pigmentation, ptosis, rachitism, epilepsy, lordosis, &c." A large number of facts are however, recorded in tables and diagrams, presenting much information. Some of his conclusions agree with those established by other observers—viz., that all forms of cranial abnormality are co-related with mental dulness; that the children of the labouring classes (poorer children) are less delicate—or at least not more delicate—than those of the upper social classes; and that several abnormalities in growth are often associated in the same child. This is markedly characteristic of imbeciles. There are certain well-established constitutional differences between boys and girls, the former presenting a larger proportion deviating from the average, while there is a smaller proportion of dull girls than boys. This proposition is important in many ways and is admirably illustrated by Mr. G. Udny Yule in a recent paper published in the Philosophical Transactions "On Association of Attributes in Statistics, with Illustrations from the Material of the Childhood Society, &c.," drawn from Dr. Francis Warner's observations and papers in the Journals of the Royal Statistical Society. Dr. MacDonald's book contains a full illustrated catalogue of anthropometric instruments collected from all countries, also a useful bibliography of the American and European literature of child-study.

## WORD-DEAFNESS, WITH SPECIAL REFERENCE TO THE "NAMING CENTRE" IN THE BRAIN.

DR. GRAEME M. HAMMOND has published in the *Journal of Nervous and Mental Diseases* for July, 1900, an account of a case which appears to throw an interesting light on the localisation of the so-called "naming centre" in the brain, the existence of which was first postulated by Sir W. H. Broadbent and subsequently confirmed by a case reported by Dr. C. K. Mills of Philadelphia. In a former case recorded by Dr. Hammond and referred to in these columns[1] the man made an excellent recovery from the operation of trephining and soon regained the power of naming objects, but the word-deafness had never entirely disappeared and he found it difficult to pronounce words of three syllables or more. The following case is that of a man, aged 40 years, who was taken into the Charity Hospital, New York, on Jan. 9th, 1900, in a comatose condition. He soon recovered from the coma and there was no motor weakness or marked disorder of sensibility. The special senses appeared to be unimpaired. He was almost completely word-deaf and completely word-blind, besides being unable to write a word (agraphia) from dictation or copy a simple geometrical figure. He was, however, by no means stupid. Dr. Hammond thinks that if the patient had lived a diagnosis of lesion of the superior temporal convolution and of the angular gyrus would probably have been made, and yet neither of these regions had been implicated at all, as shown by the necropsy which revealed a softening of the middle third of the second temporal convolution, a position intermediate between the auditory word centre and Dr. Mills's "naming centre," the latter being located by Dr. Mills in the inferior or third

[1] THE LANCET, Feb. 24th, 1900, p. 552.

temporo-sphenoidal convolution. Dr. Hammond wished to emphasise the fact that in a given case of word-blindness or word-deafness it was not possible to say definitely what was the exact site of the lesion "further than that it involved some part of the speech area." In the discussion following the reading of the above communication at a meeeting of the New York Neurological Society Dr. Joseph Fraenkel stated that he had at present under observation a syphilitic man, aged 40 years, who suffered from impaired mental faculties and a spastic paralysis of the right upper extremity. In addition he was absolutely unable to name any object shown to him, but he could define the uses of the object. In this case Dr. Fraenkel felt convinced that there was a lesion in the arm centre sufficiently large to encroach slightly upon the speech centre. A slight lesion in the speech area would lead to marked disturbance of the higher and more complex functions associated with speech.

## HERTFORD BRITISH HOSPITAL IN PARIS.

THIS hospital, on the death of the late Lady Wallace, was transferred to Her Majesty's Government who have appointed a committee to manage it consisting of the Honorable Michael Herbert, C.B., Mr. Austin Lee, C.B., Mr. A. Percy Inglis (Her Majesty's Consul-General), Mr. John Pilter, and Mr. Alfred Coleman. Her Majesty's Office of Works recently instructed Professor Corfield, Inspector of Buildings for the Department, to investigate the sanitary arrangements of the institution, and he has reported that in his opinion the hospital, which had been closed for temporary repairs, cleaning, &c., should not be reopened until extensive alterations have been made in the present sanitary arrangements. Meanwhile, to obviate any inconvenience which may result from the non-admission of urgent cases among the British poor resident in Paris, instructions have been given to the resident medical officer to take immediate steps to obtain admission to a suitable French hospital for any such applicants.

## THE CEREBRAL SYMPTOMS OF POISONING BY GAS.

ON Friday, Sept. 14th, four persons living in the suburb of Tottenham, in North London, were poisoned by gas that had escaped in a bedroom, with the result that two of the cases ended fatally and the other two sufferers only recovered after being taken to the hospital and medically treated. In a recent number of the *Neurologisches Centralblatt* (No. 13, 1900), Weygandt has published an account of his experiences of poisoning with the products of combustion of gas in an unventilated room. He heated the air in a bathroom by using a gas-stove, and then proceeded to heat the bath water by the same method. He allowed the air of the room to get vitiated to such an extent that a candle would not burn in it. He then stripped off his clothes and entered the bath. As he entered the room he states that he felt a pulsation in the temples, ringing in the ears and dizziness, and a feeling of anguish and distress. He was soon compelled to leave the bath, though he had no clear recollection of this, and went to his bedroom, where he became unconscious. On regaining consciousness he found himself lying on the floor. He now suffered from vertigo and intense headache, and had a general feeling of apathy and utter indifference to things around. He imagined at the time that he had had an epileptic attack. He rose up and went into another room and again became unconscious. On coming to he found that he had vomited, and was now feeling extremely weak and hearing a roaring sound in the head. He sent for a medical colleague, and when the latter arrived he (Weygandt) stated that he thought he was suffering from gastric irritation and poisoning due to some preserves he had eaten. Shortly afterwards, however, his recollection grew clearer and he was able to state the real cause—viz., poisoning by the products of combustion of gas in the bathroom. In cases of poisoning by ordinary illuminating gas the symptoms appear to be somewhat similar—viz., giddiness, præcordial distress, and shortness of breath (dyspnœa) soon passing into unconsciousness. The intense headache and the vertigo experienced after recovery or resuscitation are also characteristic of both kinds of poisoning. In Weygandt's case it was interesting to note the condition of amnesia for the events preceding each attack of unconsciousness, and for the gastric irritation and vomiting which preceded recovery. The practical lesson to be learnt is the necessity of having a full ventilation in sleeping-rooms and in bathrooms, and especially in the latter when gas-stoves or geysers are used to warm the air of the room or the water of the bath itself.

## DEAD BODIES AND PASSERS-BY.

A CURIOUS piece of evidence, but one by no means without precedent, was given recently before the coroner for Market Drayton. The inquest was upon the body of a man which had been found head downwards in a small well or pit full of water sunk in a ditch by the wayside, and it was admitted by a witness that he had seen the deceased in this position and had made no attempt to extricate him, preferring to leave what might or might not at that time have been a dead body for the police to deal with, and proceeding to inform them accordingly; moreover, from the remarks of the coroner it was believed that other persons had exercised an equally ill-judged forbearance. This hesitation on the part of uneducated persons to interfere with what is apparently a corpse arises perhaps in some measure from a superstitious dread of handling a dead body, but has no doubt been encouraged by the attitude of the police, who, from the point of view of detectors of possible crime, not inexcusably prefer to see the body in its original position and to be able to search for traces of the criminal before such traces may have been removed without being properly observed. There is also some risk that the passer-by who endeavours to be the first to render assistance where a crime has been committed may himself be seized upon by a second arrival as being the criminal himself. It is painful to believe that a confusion thus arising in the minds of the ignorant may induce them to consider that they are under legal obligation to inform the police rather than to assist a fellow creature who may still be alive and within reach of succour, but at the same time it is consoling to reflect that only the very ignorant or the brutally indifferent would refrain from immediate action in circumstances such as those described at Market Drayton. Not to help a man still obviously alive would imply a callousness which is hardly human and which we hope is very rarely if ever met with.

## A GERMAN MILITARY HOSPITAL.

THERE is a very well-executed plan, or rather model, of the new military hospital at Potsdam in the German section of the Paris Exhibition, and all visitors interested in army hygiene are presented with a pamphlet containing a full description of the establishment. The following particulars have been extracted from this document. The Royal Military Hospital of Potsdam stands upon elevated ground 1200 metres to the north of the town and about the same distance from the barracks. The enclosure contains nearly 12 acres, of which space the buildings occupy about one-eighth part, the remaining seven-eighths being taken up by roads, pathways, yards, and gardens. The total number of

beds is 309, including three for officers, each bed being allowed 9·5 square metres of floor space and 38·5 metres of cubic space. There are in all 14 blocks, the cost of construction per bed, without counting the price of land and material, having come to 4469 marks, or nearly £220 sterling. The cost of furnishing and equipment came to an additional 133 marks, or about £6 10*s*. per bed. In the machinery annex a sufficiency of power is generated to carry on the following operations, the transmission of force being effected through underground conduits. *a*. Warming by means of hot air or steam at low pressure. In the administration block coal in earthenware stoves is used. *b*. Ventilation. 60 cubic metres of fresh air per bed per hour are supplied, the air being filtered in a basement and either cooled or warmed according to season. For the removal of vitiated air aspirating chimneys have been provided in the walls. *c*. Elevation of water from deep wells on the premises and storage in tanks in the kitchen block. *d*. Electric lighting throughout, except in the offices, where gas is provided. *e*. Steam cookery on the system of A. Senking of Hildesheim. *f*. Steam laundry. *g*. Hot water-supply for baths and ablution rooms. *h*. Disinfection. The resident staff comprises one medical staff officer on guard, one chief inspector, two inspectors, nine junior assistants, one cook, four under-officers of police, 26 under-officers of the sanitary corps, 14 military ward-orderlies, and one compounder. The patients are divided into four classes according to their maladies, each class having its own medical director who has the assistance of one or more junior medical officers. The research laboratory is fully equipped in every way according to the most modern of ideas and in like manner the operation theatre is fitted with the most recent appliances and instruments. Special provision has also been made with a view to the medico-mechanical treatment of injuries and deformities, including massage, and there is a complete installation for the treatment of disease by electricity. Finally, the hospital and all that it contains are placed under the direction and control of a medical officer in chief who is held responsible for administration, including the maintenance of good order and discipline.

## THE SPREAD OF INFECTION.

EXACTLY how to bring home to the working classes the necessity of isolating cases of infectious disease is one of the most perplexing problems of our present-day public health administration. In spite of popular lectures, of the wholesale distribution of leaflets, and even of the warning conveyed by occasional more or less heavy police-court fines, the history of nearly every epidemic demonstrates that "personal infection" plays a most prominent part in keeping the outbreak alive. One of the most flagrant instances of callous indifference to the spread of infection that has been brought to our notice comes from the Rhondda Valley in South Wales where a grocer's wife was fined last week for exposing herself in her husband's shop while suffering from scarlet fever. It appears that at the end of July she herself, three children, and a servant were attacked with scarlet fever and that one child died. It might be supposed that this last fact alone would have impressed her with the serious nature of the illness and that she would have been especially careful not to pass it on to her neighbours, but her conduct shows that she was quite unconcerned as to what happened to them. The woman was taken ill on July 25th and the sanitary inspector visited her house and gave the customary verbal and printed instructions as to isolation, laying especial stress upon the danger attaching to her taking part in her husband's business. Ten days after this she was seen by the inspector serving in the shop, and upon his representing to her the serious risk to which she exposed those with whom she came in contact she undertook to confine herself to the house for the requisite period. At the end of three weeks from the onset of the disease she was again seen in the shop by the medical officer of health who there and then examined her and found that she was profusely peeling and was in an undoubtedly infectious condition. Notwithstanding that she was told at this time that she would be prosecuted and that if she were again seen in the shop the fact would be pressed before the magistrates she was seen serving customers upon two subsequent occasions. The fine of £3 with costs amounting to 10*s*. inflicted by the stipendiary magistrate will hardly under the circumstances be considered excessive; indeed, it is almost justifiable to regret that section 126 of the Public Health Act, 1875, permits only a pecuniary fine and does not allow a term of imprisonment to be imposed. If a collier is found in a mine with a match in his possession he is sent to prison for imperilling the lives of his fellow-workmen, and it is not unreasonable for him to require that his wife and children when they go to purchase the household groceries shall not have their lives imperilled by such criminally thoughtless conduct as that upon which we have commented.

## BRITISH MEDICAL BENEVOLENT FUND.

AT the September meeting of the committee of management 17 urgent applications for help were considered, but the balance available for grants was only £88 2*s*. 7*d*. Dr. Swallow of Clapham was elected an honorary local secretary and the committee will greatly appreciate offers of help from members of the profession willing to accept this office. Four annuitants were elected to fill vacancies caused by deaths since the last meeting. It is hoped that friends of the fund who have not yet done so will send in their subscriptions for the current year and also endeavour to interest others in the work of the charity.

## ALARM OF CHOLERA IN SYRIA.

WE learn from our Constantinople correspondent that on Sept. 12th Dr. Coussa of Aleppo telegraphed to the health office in Constantinople that cases resembling cholera had occurred in the village of Tcherkess-Ouchaghi, near Alboustan. All the patients died within 24 hours. The municipal medical officer of Marach and another medical man immediately proceeded to the place to investigate the circumstances and to ascertain the nature of the disease. They were also authorised to carry out all requisite measures of disinfection and to isolate patients suffering from illness of a doubtful character.

## CEREBRAL TUMOUR WITH UNUSUAL OCULAR SYMPTOMS.

DR. MAX LINDE in a recent publication[1] records what is probably the first case of a cerebral tumour producing hemianopsia in one eye, in which the disease was verified by necropsy. The case was that of a man who suffered from symptoms of loss of smell and partial paralysis of the right external rectus muscle. There was some failure of memory. The affected eye was hemiopic, with preservation of macular vision, and Wernicke's hemiopic pupillary symptom was elicited. Ophthalmoscopic examination showed the presence of double optic neuritis with choked discs. The tongue when protruded deviated slightly to the right. The necropsy revealed a tumour of the brain in the region of the hippocampal and uncinate gyri on the right side and pressing upon the right abducent (sixth) nerve. This nerve was partially atrophied. The optic tract of the left side was apparently enlarged from the growth of the tumour which infiltrated its substance, and

[1] Monatsschrift für Psychiatrie, No. 7, 1900.

examination with Marchi's method demonstrated the presence of degenerated fibres (staining black) in the optic chiasma and in the inner part of the right optic nerve, thus accounting for the uniocular hemianopsia. The localisation of the growth in the uncinate and hippocampal gyri also served to explain the early symptoms of loss of smell. The position of the tumour was such as to render its removal by surgical operation impossible.

THE prize of 15 guineas offered by the Cancer Society, 315, High Holborn, through the liberality of Miss Scott, for the best original essay on the present state of "cancer science" has been awarded to Mr. Alexander Fraser, M.D. Aberd., of Queen's Park, Manchester, the adjudicator being Mr. George Brown, M.R.C.S. Eng.

THE autumn meeting of the Northern and Midland Division of the Medico-Psychological Association will be held at the Newcastle City Asylum, Gosforth, on Wednesday, Oct. 3rd, 1900.

THE opening address at the London School of Tropical Medicine, Connaught-road, Albert Dock, will be delivered by Sir William McGregor, M.D. Aberd., on Oct. 3rd at 9 P.M.

A REUTER'S telegram of Sept. 14th from Brisbane states that three fresh cases of plague have occurred there, bringing the total up to 123, with 53 deaths.

## THE WAR IN SOUTH AFRICA.

WAS there ever a time when the daily press contained such an amount and such a variety of exciting news as at the present moment? Editors must be surfeited with the harvest of subjects and intelligence arriving from all quarters. The flight of ex-President Kruger, the rapid and, it may even be said, the tumultuous progress of the war in South Africa to its inevitable end, together with the telegraphic summaries of the evidence given before the Royal Commission; the stirring events in China, the West Coast of Africa, and elsewhere; the plague in Glasgow and its progress abroad in different parts of our Empire; the dissolution of Parliament to be rapidly followed by a general election—these form only a part of what meets the eye of the readers of morning and evening papers. There is not much need to have recourse to any news not "officially confirmed" in order to fill the columns of our newspapers. The result of it all if absorbing is rather bewildering and not conducive on the whole to habits of steady or concentrated attention or thought and in a general way, perhaps, unwholesome, but there it is and it is unavoidable.

We need make but little reference to the military events in South Africa, because we shall have been forestalled by what has appeared elsewhere in the daily press and such events are just now moving too rapidly to keep pace with them. Touching the South African Royal Commission we may say that the Commissioners have already accumulated a large amount of evidence at the scene of the war and have inspected most of the military hospitals there. Their work in South Africa will consequently soon be coming to an end, when they will return to this country, examine some other witnesses, and then proceed to sift the evidence and to formulate their report. We have no desire, and it would be improper, to anticipate the result. The investigation is in excellent hands and the legal training and ability of its president will ensure that the evidence is thoroughly sifted, weighed, and considered.

As we have said elsewhere, assuming Mr. Burdett-Coutts's allegations to have been correct, they were painful reading. It cannot be otherwise than distressing at any time to picture sufferings which are more or less inevitable in war, but to be told that they were such as might and should have been prevented or greatly mitigated seemed intolerable to people in this country. It was no wonder, therefore, that there was great anxiety to know what Lord Roberts had to say in the matter, and having learned his opinion and that of others who are in a position to know there is a natural feeling of great relief.

As regards Dr. Leigh Canney's communication to the *Standard* on the prevention of diseases in war, which has deservedly attracted a good deal of attention, we may take this opportunity of making a few remarks. It goes without saying that everyone must sympathise with the object which he has in view, and as there is sure to be hereafter a departmental inquiry into many questions connected with the field medical service and the Royal Army Medical Corps Dr. Canney cannot do better than take that opportunity for submitting his proposals for consideration. Some such idea must have frequently suggested itself but failed of being carried out owing to the practical difficulties in the way of doing it. Although it is probably quite true that in the case of South Africa the enteric fever epidemic was attributable to water pollution on a large scale it is not at all clear that this fever is always water-borne—or, in other words, that water is the sole and exclusive vehicle of its spread. If we may judge from their statements it has not been the experience of medical officers in India and elsewhere that immunity from disease can be guaranteed by the use of boiled water or of filters. As a matter of fact it has been found extremely difficult to keep the Pasteur-Chamberland or any other really efficient bacteriological filter in perfect working order on field service or to obtain promptly all the amount of filtered water that is required under the conditions of a campaign conducted on a large scale. It is also alleged to be a matter of experience that troops at the end of a long and fatiguing march will not act on the warnings given to them—the fact being that thirst dominates everything else for the time being under such circumstances. We fear that soldiers would not, consequently, be content to wait for even the half-hour required for the supply of the boiled water, and the movement and presence of dust in the atmosphere (dust storms) would probably soon nullify the sterilisation of the water. Moreover, we entertain some grave doubts as to the practicability of the transport and application of the means and appliances required for the efficient carrying out of these proposals—especially in the case of forced marches and rapid movements. *The* difficulty in all wars is invariably transport, and if military success is to dominate all other considerations in war supplies of food, forage, and ammunition must be forthcoming when and where they are wanted. If we could only get our enemy always to wait until we were ready with the necessary hygienic arrangements there would be no excuse for being unprepared. This is never likely to be the case, and however much we may be alive to the fact that contaminated water and soil and camp diseases are always and everywhere intimate associates it does not help us to know beforehand the particular place and time of their occurrence. Still, that is no reason why we should not apply ourselves to the problem before us and welcome every practical suggestion, and in that spirit we would urge Dr. Canney to put forward his proposals for the consideration of those more immediately concerned with the question which he has taken up.

### TREATMENT OF BRITISH PRISONERS OF WAR AT PRETORIA.

As mentioned in THE LANCET last week, the War Office published under the above heading on Sept. 12th a series of despatches, paged from 1 to 13, from which the following passages are taken, including the evidence of the medical witnesses in full.

From Field-Marshal Lord Roberts to the Secretary of State for War.
Army Headquarters, South Africa, Pretoria, June 27th, 1900.

SIR,—I have the honour to submit for the information of the most Hon. the Secretary of State for War a letter, dated June 7th, 1900, from Lieutenant-Colonel H. V. Hunt, R.F.A., to the Chief of the Staff, South Africa, reporting on the treatment of the prisoners of war at Pretoria and the proceedings of a Court of Inquiry which I directed to be assembled at Pretoria on June 11th to investigate the subject.

2. As regards the opinion recorded by the Court I would remark as follows:—

(*a*) I concur in the view that the treatment of the officers of the regular forces who were captured by the Boers appears to have been fairly good.

(*b*) That some of the prisoners who belonged to colonial corps raised in South Africa should have been confined in the gaol and

treated as criminals is opposed to the usages of civilised warfare, and the same remark applies to the British subjects residing in the Transvaal who were similarly treated because they refused to take an oath of allegiance to the South African Republic.

(*c*) The food of the non-commissioned officers and men is shown to have been quite inadequate in quantity and inferior in quality. There was no excuse for this, as supplies of excellent meat, bread, and vegetables are easily procurable in the Transvaal at a moderate price.

(*d*) That greater facilities were not given for religious ministration is much to be regretted.

(*e*) The inhuman treatment of the sick prisoners throws the greatest discredit on the authorities at Pretoria who must have been aware that proper hospital accommodation and equipment had not been provided, that suitable food and medical comforts were not forthcoming, and that the supply of medicines and medical appliances was wholly insufficient. That the deficiencies referred to in the correspondence were to some extent made good by the exertions and liberality of private individuals does not exonerate the Government of the South African Republic from its responsibility in this matter, and the indifference which was shown to the sufferings of the sick among the British prisoners is the more inexcusable when it is remembered that the sick among the Boer prisoners have invariably received the same care and attention as our own sick soldiers.

3. The efforts of Doctors P. H. Haylett and R. von Gernet to ameliorate the condition of their patients and the assistance rendered by the gentlemen mentioned in the latter's evidence, prominent among whom was Mr. J. Leigh Wood, officiating manager of the Natal Bank at Pretoria, are the only gratifying features in this correspondence. On the other hand, it would be difficult to condemn too strongly the conduct of Dr. H. P. Veale, M.B. (Cambridge), whose heartlessness in ignoring the disgraceful treatment of the sick prisoners and the remonstrances addressed to him by the medical officers in immediate charge of them calls for the severest reprobation.

I have the honour to be, Sir, your most obedient servant,
ROBERTS, Field-Marshal, Commanding-in-Chief,
South Africa.

---

From Lieutenant-Colonel H. V. Hunt, R.F.A., to the Chief of the Staff, British Forces in South Africa.

Pretoria, June 7th, 1900.

SIR,—I have the honour to report that I joined the main body of the officers who were prisoners of war on Dec. 22nd, 1899. They were then located in the Staats Model School, a well-built and commodious building and capable of holding about 100 officers comfortably—there were at that time about 70. The scale of rations for officers is attached (marked A), and they were permitted to supplement this by private purchases and a regular mess was established. * * * * I do not consider that the officers as a body have any real cause to complain of their treatment. * * * * I regret to say that I am unable to make such a satisfactory report as regards the treatment of the men. The scale of rations (copy attached, marked D),[1] already far too low, was frequently reduced. The one pound of meat often dwindled to considerably below that amount, and eventually had to be supplemented from the fund of which mention is made in copy of correspondence marked E.[2] For 14 days in February they were without tea or coffee. No meat was issued from Jan. 1st to 14th; the supply of vegetables was latterly quite cut off, as well as firewood from May 27th. * * * * But far more serious is the way in which our sick were treated. * * * * There were two hospitals, one at Racecourse and one at Waterval. At the former some beds were provided, but not sufficient, and no mattresses; at the latter nothing of the sort was given. When first occupied the shed was roofless and men with fever lay on a blanket, with their boots for a pillow and running water at their side. No medical comforts of any sort were provided and till the arrival of Dr. von Gernet, about the end of February, the condition of affairs was absolutely scandalous. I am sure that a great responsibility for this rests on Dr. Veale, who, as head of the Red Cross, was unwilling to risk trouble with the Government and imperil his own position. Dr. von Gernet is, however, a man of another stamp, and, first insisting on having the hospital in his own hands, he set himself to improve matters and worked so hard that his health at one time entirely gave way. * * * * I omitted to mention that after great difficulty a list, completed up to April 20th, was furnished to the officers of the number of deaths, which then amounted to 50, and I believe six more have since occurred. The burials in these cases were always carried out by a sergeant, no minister being informed of them.

The men had great difficulty in reporting themselves sick, being frequently refused admission till so ill that they had to be carried to the hospital, and the accommodation was so limited that there were a large number of out-patients who should have been admitted.

The general opinion of the men is that they have received very bad treatment on above grounds.

I have the honour to be, Sir, your obedient servant,
H. V. HUNT,
Lieutenant-Colonel, R.F.A.,
Senior Officer of British Prisoners of War.

---

Extract from proceedings of a court of inquiry assembled at Pretoria on June 11th, 1900, and following days, by order of Lieutenant-General Tucker, C.B., commanding 7th Division, South African Field Force, for the purpose of inquiring into the treatment of British prisoners, but more especially the treatment of sick prisoners in the hands of the Boers in and near Pretoria.

President.

Lieutenant-Colonel W. E. Briggs, 2nd Battalion Hampshire Regiment.

Members.

Major E. Herapath, 2nd Battalion Lincolnshire Regiment.
Major A. C. Becher, 2nd Battalion Norfolk Regiment.

The court, having assembled pursuant to order, proceed to take evidence.

Dr. P. H. Haylett, M.B. London, makes the following statement:—

In the middle of December, 1899, I was verbally instructed by Dr. Veale, the chief medical officer for military prisoners, to take charge of the hospital at the Racecourse. At this time most of the prisoners had been moved to Waterval, but the sick remained at the Racecourse. At the time I took over charge at the Racecourse there were about 60 sick. There was no adequate provision of medicines, considerable difficulty in obtaining stimulants, and no means (scrubbing brushes, &c.) of keeping the hospital building clean. I also had to complain of refuse from the hospital, such as decomposed vegetables, being left close to the building for an unnecessary length of time. The patients lay on straw mattresses on bedsteads, there were no sheets, and few pillows. The food supply was fair. I made no official complaint as regards this hospital, but sent in repeated requisitions for articles which were not complied with.

In the first week of January, 1900, I was sent out to Waterval as resident medical officer for the prisoners of war there. On the third day of my residence at Waterval I reported in writing to Dr. Veale condemning the sanitary arrangements and the water-supply, the hospital building and its equipment, in the strongest possible terms. As a result of this letter a Commission was appointed to investigate these matters, consisting of the Prisoner's Commission and Drs. Veale and Lingbeek. This Commission went out to Waterval to investigate the matter and view the hospital. At the railway station *en route* Dr. Veale suggested that I should not accompany the party, but this was overruled by the Field Cornet and I did accompany the party.

The result of this visit was a decision that the main hospital for the prisoners should be on the Racecourse and that the Waterval hospital should be only a collecting station. The President, South African Republic, strongly objected to this suggestion. Dr. Veale was equally strongly insistent on the Racecourse hospital being the main hospital.

Shortly afterwards I was ordered back to Pretoria, leaving no resident medical officer at Waterval. I resumed charge of the Racecourse hospital.

On Jan. 8th I wrote a letter to Dr. Veale, which is attached (this letter is signed by the President, Court of Inquiry, and marked M).[3] My next letter (marked N)[3] was written on Jan. 14th to Dr. Veale. It was now decided that Dr. Van der Horst was to take charge of the Racecourse hospital, while I was again to go out to Waterval as resident medical officer. On the 20th I went out there. On Jan. 22nd I sent Dr. Veale the attached report (marked O).[3] This letter, as also my preceding letters, elicited no reply and was followed by no improvement. On Feb. 6th I wrote Dr. Veale another letter which his secretary put into Dutch because he (Dr. Veale) objected to my letters being in English (this letter is marked P and attached).[3] To this letter I received also no reply. Between this date and my resignation of my appointment at Waterval I wrote to Commandant Hermann bitterly complaining of the want of meat and milk for the hospital. No result attended. I then resigned my appointment in a letter written in Dutch (marked Q).[3]

During the period I was resident medical officer at Waterval Dr. Veale did not visit the hospital except on the one occasion that he accompanied the Commission. My services to the British prisoners of war were entirely gratuitous.

Rudolph von Gernet, doctor of medicine, is examined by the Court and makes the following statement:—

On Feb. 19th, 1900, I received a letter from the Landroost of Pretoria informing me that on the recommendation of Dr. Veale I was appointed resident medical officer to the British prisoners at Waterval, to replace Dr. Haylett, who had resigned. I went about Feb. 20th to Waterval, where I found Dr. Haylett, and in company with him I inspected both the camp and the hospital. In the camp I found the prisoners housed in sheds built of strips of corrugated iron, open towards the front, and by reason of the corrugated iron sheets being old letting in the rain through the roof. The central road being higher than the floor level of the sheds the rain water drained into them. The men consequently in wet weather (and this was the rainy season) were lying in water. Each man had one blanket. There were no waterproof sheets and the men were lying on the bare ground.

The streets were in an indescribably filthy condition, rotting animal and vegetable refuse, and even human excrement, lay freely all over them, and the stench was awful. The latrines consisted of trenches seven or eight feet deep within 50 yards of the night camp in which the men slept. The heavy rain filled these trenches and the contents were floated all over the place.

The supply of drinking water was insufficient. It was stored in large tanks and I found men were in the habit of drinking indifferently from the drinking water-tanks and washing water-tanks and also of using the drinking water-tanks to wash their clothes in. The washing water was quite unfit for drinking. There was no organisation or discipline in these matters.

The prisoners' clothes were in rags, some being without trousers, others without coats or boots. The food supplied to the men was quite insufficient. Meat was only issued twice a week, and then only half a pound at a time. The result was that the men became very weak and liable to disease and I had to admit several men to hospital simply from weakness from want of proper food. They had plenty of flour. Men washed themselves and their clothes in the street, bringing the water from the tanks (which were in the night camp) in buckets. This practice tended of course to the spread of disease.

The building used as a hospital was satisfactory. The furniture was absolutely unsatisfactory. For instance, with over 60 in-patients and 20 orderlies there were only 21 bedsteads, 11 mattresses, and 49 blankets. I found nearly all the sick lying on the bare floor without bedding or pillows. There were 41 typhoid cases in the hospital and no suitable medicines whatever—that is, no medicines that I could prescribe for typhoid.

The food-supply for the hospital was quite inadequate. The ration for a typhoid case (Diet I.) was supposed to be—

1 bottle beef-tea, made of 1lb. of meat.
2 bottles of milk.

---

[1] See Appendix.
[2] Not printed.
[3] Not printed.

Frequently no meat was received, and consequently no beef-tea could be made. The milk seldom arrived.

Diet II. was supposed to be—

1 bottle of milk,
1 bottle beef-tea (as above),
Arrowroot, sago, biscuits, and rice[*],

but the meat and milk came irregularly.

[*]Matters being in this condition I went direct to the president of the committee, "Bewaaking Krijgsgefangenen," and told him of my complaints. He assembled the committee the same afternoon and I appeared and described the state of things at Waterval. The committee, it was evident, had not been previously aware of any complaints or shortcomings in connexion with the treatment of the Waterval prisoners. The committee became excited and sent for Dr. Veale. I was present and heard Dr. Veale asked who was the chief of the hospital at Waterval. Dr. Veale answered that he himself was the chief in his capacity of medical officer to the Staats Artillery. Asked again who was the responsible doctor Dr Veale said, "the resident doctor." The committee next asked Dr. Veale to whom the resident doctor was responsible. Dr. Veale answered, "To the committee." Asked why he did not report complaints and supply medicines required from the hospital Dr. Veale said he had received no letters on the subject. The committee there and then decided that Dr. Veale was to have nothing further to do with the hospital at Waterval and that the resident medical officer was the chief and would report direct to the committee. Dr. Veale stipulated that the supply of medicines for the hospitals should still go through him and this was acceded to by the committee. A week later, on my reporting that medicines were not satisfactorily supplied, the committee authorised me to get my medicines where I liked. After this President Kruger was personally and constantly in communication with the committee and with Waterval district by telephone asking if the prisoners had everything they required. After Dr. Veale's connexion with the hospital ceased I obtained from the committee the cleaning and levelling of the streets of the camp; the making of proper latrines; the supply of a second blanket and a stretcher to each man; the supply of boots and clothing; and the placing of the drinking-water supply, by sinking more wells, &c., on a satisfactory footing; and an increase in the meat. There were other necessities for the sick, such as milk and stimulants, which I was unable to obtain in sufficient quantities or fast enough from the Government. These and everything else I could possibly want I obtained from Mr. Leigh Wood. The average of deaths to the total number who passed through the Waterval hospital is 6 6 per cent.

I should like to have recorded the names of individuals who afforded me the greatest assistance in remedying the dreadful state of affairs I first found at Waterval:—

Mr. Kalt, secretary to the "Bewaaking Krijgsgefangenen."

Burghers.

Mr. Hermann, Commandant, Waterval.
Lieutenant Haupt, Secretary Rothman, Architect Van de Stadt, } On Commandant's Staff.

Prisoners.

Captain Nesbitt, Bechuana Protectorate Regiment.
Lieutenant Fulford, R.N.
Sergeant Dudley, 18th Hussars.

Civilians.

Mr. Leigh Wood and his committee.
Mr. Marks, of Lewis and Marks.
The Rev. H. W. Goodwin, Wesleyan minister.

Herbert Prior Veale, Bachelor of Medicine, Cambridge, being examined by the Court, the following questions are put to the witness and his answers are recorded below:—

*Q. 1.*—What was your position with reference to the prisoners of war at the Racecourse?

*A.*—Drs. Knobell, Lingbeek, and myself were three medical members of the Transvaal branch of the Geneva Red Cross Society. We took it in turns to take an ambulance train to the front, and when Dr. Knobell went to Natal I relieved him of the care and medical attendance of the prisoners of war at the Racecourse. This would be in November. I had nothing to do with the sanitary arrangements. It would, however, be my duty, as medical officer attending the sick, to notice and try to remedy anything in the arrangements of the hospital or its precincts which was prejudicial to health. I brought several such points to notice and consider that everything in the Racecourse hospital was reasonably satisfactory when I left at the beginning of December for the Free State.

*Q. 2.*—Were you responsible for the medical and sanitary arrangements for the prisoners of war at Waterval?

*A.*—No. I was sent over to Waterval in company with Dr. Lingbeek by the Commission at that time in charge of the prisoners to make a report *re* the sanitary arrangements, suitability of Waterval as a camp, water-supply, &c.; and we made the report to the effect that the place was unsuitable as a camp, but as the camp could not be moved we suggested a different water-supply, different latrine systems, a sanitary police as the men were behaving in a very dirty manner there. This was the only occasion on which I visited Waterval. Dr. Haylett went out with us on the above occasion. From time to time the Red Cross Committee were allowed to send out a delegate to ascertain whether they could do anything of benefit, and the delegates made written reports to the committee.

*Q. 3.*—Did you receive any letters from Dr. Haylett making complaints and suggestions with reference to the condition of sick prisoners at Waterval?

*A.*—I received no letters with reference to the condition of the prisoners but received two or three letters from him in English with regard to the supply of medicines. I was told afterwards that Dr. Haylett had written me no less than 12 letters, not one of which I received. I saw Dr. Haylett, on an average, every other day, and he never mentioned having written these letters.

*Q. 4.*—Did you or did you not receive the letter marked M from Dr. Haylett, which has now been read to you?

*A.*—I cannot say whether I received this identical letter or not, but I did receive some letters from Dr. Haylett before the date of my visit to Waterval, which referred merely to the supply of medicines. I consider this letter to refer merely to the supply of medicines.

*Q. 5.*—Can you recollect answering any letter that you received from Dr. Haylett?

*A.*—I cannot recollect answering any particular letter, but I will undertake to produce my letter-book, in which copies of all letters written by me are kept, and if I ever wrote to Dr. Haylett copies of my letters to him will be found there.

*Q. 6.*—Did you receive the letter marked N, or the letter marked O, which have now been read to you?

*A.*—No. I have never seen or heard the contents of either of these letters before.

*Q. 7.*—Did you receive the letter in Dutch marked P which is now handed to you?

*A.*—I did receive the letter marked P and forwarded it to the Commission.

*Q. 8.*—Did you answer this letter to Dr. Haylett?

*A.*—This letter was written in my own office and any answer would be verbal. The letter was written for the purpose of being forwarded by me to the Commission.

*Q. 9.*—What is your own opinion as to the extent of your connexion with, and responsibility for, the hospital at Waterval?

*A.*—I do not consider that I had any responsibility whatever, and my only connexion with the hospital was that I was practically a supplying chemist and Dr. Haylett drew his medicines through me.

*Q. 10.*—Were you responsible in any way that the British prisoners in gaol received proper medical attendance?

*A.*—No; I was not responsible in any way. Lieutenant Tarbutt and another prisoner, a land surveyor, were brought very ill with typhoid to the Bourke Red Cross Hospital (of which I was the doctor) from the gaol and died there.

*Q. 11.*—Do you think that Lieutenant Tarbutt and the other prisoner contracted the typhoid fever in gaol?

*A.*—Yes.

[The non-medical witnesses who gave evidence before the court of inquiry were—(1) Mr. J. Leigh Wood, manager of the Natal Bank, Pretoria; (2) Rev. H. W. Goodwin, Wesleyan minister, Pretoria; (3) Mr. Johannes Jacobus Haupt, assistant commandant of the prisoners' camp; (4) Mr. Egbert Kalt, secretary to the Bewaaking Krijgsgefangenen; (5) Sergeant S. Dudley, 18th Hussars; (6) Captain R. H. Nesbitt, Protectorate Regiment; (7) Mr. C. G. Dennison, intelligence officer; and (8) Mr. C. V. de V. Van der Spuy, accountant of the National Bank at Zeerust. A letter was also received from the Rev. J. Godfrey of Pretoria stating that after the escape of Mr. Churchill he must discontinue his regular ministrations. The opinion of the court and the scales of rations are given hereunder.]

## OPINION.

The Court, having carefully considered the foregoing evidence, so far as it relates to the allegations contained in the letter of Lieutenant-Colonel H. F. Hunt, R.F.A., dated June 7th, 1900, are of opinion:—

1. That the treatment of the officers of the Imperial Army who were prisoners of war appears, on the whole, to have been fairly good.
2. That the treatment of some of the colonial prisoners was severe and unjustifiable, inasmuch as they were thrown into a common gaol and not treated as ordinary prisoners of war.
3. That the non-commissioned officers and men were very badly fed and the scale of diet (which was not even adhered to) was, in the matter of meat, a starvation ration.
4. That religious ministration was sparingly granted.
5. That the general treatment of sick prisoners was very bad and has not been exaggerated, and that there is no doubt the prevalence of sickness and the many deaths which occurred amongst the prisoners were attributable to the gross neglect of most ordinary sanitary precautions.

Signed at Pretoria this 24th day of June, 1900.

W. E. BRIGGS, Lieutenant-Colonel, 2nd Battalion Hampshire Regiment.
E. HERAPATH, Major, 2nd Battalion Lincolnshire Regiment.
ANDREW C. BECHER, Major, 2nd Battalion Norfolk Regiment.

Pretoria, June 25th, 1900.

---

Deputy Adjutant-General, Army Headquarters,
I concur in the opinion of the Court,
C. TUCKER, Lieutenant-General, Commanding 7th Division.

---

## APPENDICES.

### A.

Scale of Rations supplied to Officers.

Half a pound meat daily; one pound bread daily; sugar as required; salt as required; potatoes as required (supply fails sometimes); tea as required; coffee as required. Meat has generally been of very inferior quality. No sugar was supplied from Jan. 15th to March 10th, Government stating that sugar at 2*s.* 6*d.* a pound was too expensive for a ration.

---

### D.

Scale of Rations supplied to Men.

Half a pound of meat twice a week; half a pound of potatoes daily; half ounce tea or coffee daily; one pound bread or biscuit daily; half pound Boer or mealie meal twice a week; about two ounces rice about twice a week; one pound fresh vegetables once a week (carrots and vegetable marrows); sugar occasionally; salt sufficient; very little pepper. Bread often sour. Supply of vegetables stopped in May.

## SOME NOTES ON THE CAMPAIGN IN AUGUST.

BY ALFRED D. FRIPP, M.S., F.R.C.S.,
SENIOR SURGEON TO THE IMPERIAL YEOMANRY HOSPITAL.

(*Continued from p. 826.*)

One of the essential differences between a civilian and a military hospital is that in the latter many of the patients are convalescent and not only need no nursing but are well enough to resent rather the restrictions upon their freedom which are entailed by the presence of a nurse. We got over this difficulty at the Imperial Yeomanry Hospital by arranging the huts and tents roughly in three classes—A, B, and C. Class A includes all the acute and serious cases and the bedridden patients. These are housed in huts. Both a day nurse and a night nurse are provided for every 22 to 34 beds (according to the size of the hut), with an "extra" sister lent for a longer or a shorter time when necessary. Thus every bad case gets a really adequate share of the nurse's attention, which cannot be ensured when one has to divide her attention among many huts or tents containing 100, or perhaps 200, cases of all sorts and degrees of severity. Class C is the "convalescent camp," and only those patients are sent into it who are on ordinary diet and taking no medicine, and who require no nursing or even temperature-taking but only the daily visit of a medical officer and the disciplinary oversight of an orderly. The patients are housed in a group of bell-tents separate from the rest of the hospital. Each tent accommodates three beds luxuriously and four with ease, while at times of stress a fifth or a sixth patient can be made comfortable. The occupants of each tent are responsible for its good order and cleanliness and for their own "service." Class B includes the patients who have recently come out of the "serious" huts in Class A, or any that are not sufficiently ill when admitted to hospital to be sent into these huts. A few of the patients are still bedridden, but none are acutely ill, for directly such a case occurs he is moved back into Class A. On the other hand, as soon as they are well enough the patients are moved on into Class C. The patients in Class B are housed in the tortoise and hospital marquees, each of which holds eight to 10, or in times of stress even 13, beds. They are looked after by the less experienced amongst the sisters (the best qualified being promoted to fill any vacancy that may occur among the staff specially selected for service in Class A), each sister on day duty having 50 beds and on night duty 100 beds (about) to look after.

This plan has worked out very well. We are never hard up for vacant beds in Class C, because we can always put extra beds into the bell-tents or telegraph to De Aar for carriages and send 100 patients down the line to Victoria West where there is a convalescent camp for 1000 men. There are similar camps for 1000 convalescents each at Bloemfontein, Norval's Pont, and Cape Town and smaller ones elsewhere along the railway line. These convalescent camps were not instituted till comparatively recently—about two and a half months ago, I believe. They have been of great service, for by enabling the hospitals to avoid blocking up their own beds with convalescents who are not yet quite fit to return to duty they probably prevented a breakdown during the height of the enteric fever epidemic. Only patients who are fully convalescent and fit to eat ordinary rations and who need no "extras" or nursing or medicine must be sent to these camps, for they are in no sense staffed or equipped as hospitals. There is a medical officer at each camp and a handful of orderlies, but the nature of the establishment is indicated by the fact that the commandant is a combatant officer.

We have never had any difficulty in providing beds in Class B. There are always a good many patients lingering there who are fit to go into Class C. Class A is where congestion is apt to occur, for the sister and the medical officer who have seen a patient through his operation or through the acute stage of his illness are naturally reluctant to "lose him," and typhoid fever is a disease which pins its victim to the same bed for a long time; but there are two very human emotions which are found in practice to compensate for this tendency and to make for the evacuation of the beds sufficiently early to ensure that there are always enough vacancies, even in Class A, to satisfy any sudden call. The first is that a sister hates to "upset her ward" by crowding in extra beds, which is her only alternative, and the second is that the patient is looking forward to his move from Class A to Class B, because it is well known to carry with it an increase of freedom (there is not the slightest doubt that the vast majority of Tommies prefer the tents to the huts) and also an alluring variation of diet. This plan has worked very well with us, and if a new army medical service had to be schemed I cannot but think that it would be a good thing to have a "convalescent camp," or Class C, attached to each non-mobile military hospital; or to put it in another way, I should like to see each non-mobile military hospital divided into two equal-sized parts. In practice it is very easy for either half to enlarge temporarily at the expense of the other when necessary. Of the two halves X (the hospital proper) would be accommodated in huts or tortoise-tents or hospital marquees, or buildings when available, and would be provided with nurses in the proportion of one to every 10 beds, while Y (the convalescent camp) would be provided with bell-tents. Since it would be a very convenient thing if a large military hospital was an exact multiple of a small one and a very good thing if large and small alike could be arranged on a plan which would permit of easy and rapid expansion from a peace to a war footing by means of the preconcerted assimilation of civilian reinforcements, I would suggest that four classes of non-mobile hospitals should be instituted. The equipment of each class of hospital should always be kept up to war strength, but only half of it should be in use while stationed at home, when it should be served by that half of the *personnel* which is detailed to it by the Royal Army Medical Corps. The other half of the equipment would only be brought into use and the other half of the *personnel* would only be appointed when the hospital was sent on foreign service, and such *personnel* would be chosen from civilians who would be temporarily attached. Convenient sizes for these four classes of non-mobile hospitals would be the following:—

| — | Class I. | Class II. | Class III. | Class IV. |
|---|---|---|---|---|
| Hospital beds: | | | | |
| On home service | 400 | 200 | 100 | 50 |
| Add when on foreign service | 400 | 200 | 100 | 50 |
| Convalescent camp beds: | | | | |
| On home service | 400 | 200 | 100 | 50 |
| Add when on foreign service | 400 | 200 | 100 | 50 |
| Total | 1600 | 800 | 400 | 200 |
| Medical officers: | | | | |
| Royal Army Medical Corps | 9 | 6 | 4 | 3 |
| Add when on foreign service— | | | | |
| Civilians qualified | 15 | 10 | 5 | 2 |
| Civilians unqualified | 14 | 8 | 4 | 2 |
| Total | 38 | 24 | 13 | 7 |
| Nursing sisters: | | | | |
| On home service | 40 | 20 | 10 | 5 |
| Add when on foreign service | 40 | 20 | 10 | 5 |
| Total | 80 | 40 | 20 | 10 |
| Wardmaids: | | | | |
| On home service | 16 | 8 | 4 | 2 |
| Add when on foreign service | 16 | 8 | 4 | 2 |
| Total | 32 | 16 | 8 | 4 |

The numbers, especially of the medical officers, are only roughly suggested. The idea is that a hospital of any size should be able to divide rapidly on emergency into two equal smaller hospitals and to despatch one of these smaller hospitals with a full staff and yet retain enough officers and non-commissioned officers to work its own beds until a reinforcing draft arrives. The equipment of one class should differ from that of another class in hardly anything but quantity. The rank of the senior officer, and indeed of the officers and non-commissioned officers under him, should of course be higher the larger the hospital. In this way steps up the ladder of promotion would be provided for on a steady scale. There should be one "sister" to every four "nurses," and promotion should be open from the latter to the former rank. I am strongly in favour of the employment of unqualified but highly-trained medical students for

foreign service. The largest or first-class hospitals would probably seldom be mobilised, but under this scheme each such equipment would easily be available for forming smaller units.

There is a good deal of difficulty in securing the services of the right class of woman to act as "wardmaid," but I think that if an endeavour was made to form such a class it would be found very useful, especially on active service. Not only do the nurses require waiting upon but there is a good deal of work of one kind and another about a hospital besides actual nursing which is better done by women than by men, notably the laundry and the dairy work.

There is a horrible custom which is apparently universal throughout South Africa (the land of empty meat-tins and of people who are too lazy to build proper drains or to bore for water) of bringing the milk to market in old glass and beer-bottles and of selling it at so much a bottle. The vendor takes no steps to clean the bottles and he considers that six of them, whether large or small, full or partly empty, are equal to a gallon. Now here was an instance in point. Until we took the collection, sterilisation, and distribution of the milk out of the hands of the army man and put it into the hands of one of the sisters the milk was continually going sour and the farmers were being regularly overpaid. But the sister very soon taught them to measure it properly and already she has saved the committee her year's salary, though she delegates the overseeing of the actual work of the dairy to whichever sister is temporarily incapacitated from work in the wards. Again, we most fortunately brought out from England Miss Cheesman to act as housekeeper and business manager to our nursing sisters. She has proved simply invaluable, for, in addition to her other work in which she has been assisted by 10 wardmaids, she has taken entire charge of the work of the laundry which, in a camp of 600 to 1200 inhabitants, is a big job by itself. It is to be hoped that the time has come when it will be considered criminal ever again to dispatch a non-mobile sanitary hospital from England without a steam steriliser and a complete laundry and large filter plant all capable of being worked by one boiler. The expense cannot matter to a country like England, and if by any bad chance it should really prove impossible to work in any particular case we should at least feel that we had done our best to put modern ideas of cleanliness at the service of Tommy when sick. To put it on the lowest possible ground it is an expensive thing to the country unnecessarily to lose men over whose training and transport and feeding much money has been spent, and it is not much good to go to the expense of keeping up hospitals and a Royal Army Medical Corps if we do not give them the best possible tools for staving off disease. "All right, try it if you like, but when you are as old as I am you'll know the uselessness of it," is a mode of damping the endeavour to bring modern methods and appliances to the service of the State which has become considerably and deservedly discredited of late. The pity is it was ever permitted to curb effort, but it is to be hoped that it is now dead, along with several other methods of doing things which this war has proved to be obsolete.

Small as has been the amount of operative surgery done here in the last few weeks I have had a few cases both of ordinary or civil surgery and of bullet-wounds which it may be of interest to record briefly. Among the former are the following:—

1. A successful nephrolithotomy urgently called for in an officer who was invalided from Pretoria with about the most continuously agonising pain that I have ever seen caused by a stone. It proved to be a small oxalate one, lying loose in the pelvis of the kidney, and its removal was attended by immediate and complete relief and was followed by perfect healing.

2. A large chronic burrowing abscess of the sacral region which rendered another officer quite unable to keep upon his horse. He had had an abscess there for four years, during which it had twice been "opened." A small caudal dimple attracted my attention and under the anæsthetic it admitted the blunt end of an ordinary small probe for an inch—passing upwards in the subcutaneous tissue of the middle line. I slit up this epithelial tube and found that it contained a wisp of hairs varying from an inch to an inch and a half in length. Their attached ends were at the skin orifice of the tube and their free ends were lying loose in the cavity of the abscess. I excised the whole suppurating area, leaving a wound from two to three inches wide and four inches long, but, as in this wonderful land it seems to make very little difference to the healing of a wound whether it be really clean or only slightly infected, I brought the surfaces together by superficial and deep stitches. Sure enough nature was equal to the occasion and immediate union occurred, not of quite the whole length of the wound but throughout enough of it to curtail very materially the time which it would have taken if the whole area had been left open to granulate up.

3. Of typhoid abscesses we have seen very little, only a few subcutaneous and parotid ones. We have only opened three abdomens in typhoid fever patients, Mr. Raymond Johnson did one, but there was advanced general peritonitis and the patient died. I have done two, the first with an exactly similar result to the last case. The second was in a vigorous, well-nourished patient who had come to us a few days before as convalescent from simple continued fever. Dr. Black, his medical officer, had taken the precaution to keep him in bed on milk diet for a few days and while still under this treatment he was seized with sudden colic. Dr. Washbourn and Dr. Black asked me to come and see him with them. The pain was localised to the right iliac fossa which was also tender and very hard and the whole of the abdomen moved very little with respiration. He had nausea, but not vomiting. There was not much evidence of shock, the pulse being normal in rate and volume. We thought it was very doubtful whether there was any perforation, but we considered that it would be safer to explore at once than to wait. I made an incision in the right linea semilunaris half way between the anterior superior spine and the umbilicus and explored the whole of the ileum and the ascending and transverse colon. All we found was (*a*) some huge mesenteric glands and (*b*) several swollen areas within the ileum on its unattached surface (the ulcers seen in our mortuary here in cases of enteric fever have often been of the hypertrophic variety). We found (*c*) one such mass making the ileo-cæcal valve feel as if there was the apex of an intussusception projecting through it, (*d*) that the appendix was some three and a half inches long and of the size of an ordinary lead-pencil and so congested that it felt like a tightly injected brachial artery in which the injection had not yet quite "set," and (*e*) that the peritoneum about the ileo-cæcal junction was acutely congested but quite smooth. I immediately sewed up the wound and primary union occurred, while the patient went through a relapse of his enteric fever. He got well and went home.

Before leaving the subject of civil surgery I would add that morphia seems, when called for, to be needed in larger doses out here than at home and that we are constantly seeing fresh cases in which head symptoms that look at first sight as if they were due to bullet wounds or to concussion rapidly cleared up under a course of iodide of potassium.

Among the cases of gunshot wound at present under my care are:—

1. An officer from whose calf Mr. Hall-Edwards's most accurate x-ray localisation enabled me to remove with great ease and rapidity no fewer than 10 pieces of a leaden bullet which were lying at depths varying from half an inch to two inches and keeping up suppuration.

2. A most interesting and severe case of bullet wound of the base of the skull. The bullet passed inwards and slightly backwards and downwards through the zygoma on the right side. There was complete facial and auditory paralysis and considerable involvement of the fifth cranial nerve all on that side. No exit wound could be found. There was such violent bleeding from the right external auditory meatus that after repeated trials of other means of arresting it I was driven to ligature the common carotid. As there was also commencing optic neuritis with rigors and some swelling just below the mastoid process I thought it wiser to put a ligature round the internal jugular vein at the same time. The hæmorrhage ceased, the wound in the neck healed perfectly, and for a time all went well, but later an abscess developed in the pterygoid, mastoid, and parotid regions and hæmorrhage from the meatus recurred. So I made an incision widely curved from the entrance wound of the bullet backwards above the pinna and downwards behind it to the tip of the mastoid and turned the flap downwards with the pinna attached. The condyle of the mandible and several fragments of bone derived from the ramus and from the pterygoid plates were found lying loose in a large abscess among the pterygoid muscles and were removed. The abscess cavity was drained and the hæmorrhage arrested by plugging and by leaving a pair of Spencer Wells's forceps

on a vessel in the periosteum of the mandible. The patient made an uninterrupted recovery and despite the loss of one of the condyles of his mandible he can now masticate ordinary diet, including chicken and beef. The optic neuritis did not progress, but on the contrary Mr. Cargill thinks that it may be clearing up. In fact, the subject of these extensive injuries has now no signs remaining except the facial paralysis, the unilateral deafness, and the scars.

There is a group of three interesting cases of paraplegia.

1. In this case Mr. Hall-Edwards localised the bullet lying two inches deep, parallel with and almost accurately in the middle line with its nose downwards at the disc between the first and second lumbar vertebræ. The entrance wound was three inches to the left of the twelfth dorsal spine. Its low position in the canal gave room for hope that the cord at least was not irretrievably damaged, and as there was severe pain shooting down the left leg which, with the sphincters of the bladder and rectum, remained absolutely paralysed after 10 weeks, while the right leg had recovered almost completely within a few days of the infliction of the wound, I removed the laminæ of the first and second lumbar vertebræ and extracted from the spinal canal the bullet and also a spicule of bone of about the same size and shape which had been driven in and which, with the bullet, was compressing the theca severely. I did not open the theca, which expanded to its natural size directly the compressing agents were removed. The wound healed well. The pain down the leg ceased at once and within a fortnight of the operation the patient was able to hold his urine for two hours (which he had never been able to do since the injury) and there was a most encouraging return of function in some of the motor and sensory nerves of the left leg.

2. This patient presents complete motor and sensory paralysis of both lower extremities without any wasting of muscles and without any visceral symptoms following on an injury which must have been a slight one. The history he gives is that a shell knocked a basket out of his hand and buried itself, without exploding, in the ground close by. He lost consciousness and fell to the ground and has been in his present condition ever since he was picked up. We have been watching him for some weeks and I have formed a strong suspicion that he is malingering.

3. This patient has apparently had his cord completely and cleanly divided by a Mauser bullet which crossed it transversely at the junction of the cervical and dorsal spine. The wound of entrance is two inches above the left clavicle at the anterior border of the trapezius. Mr. Hall-Edwards got an excellent skiagram which shows no abnormality except a bullet lying loose in the right axilla. There is complete anæsthesia below the region supplied by the cervical plexus. There is no zone of hyperæsthesia. The breathing is entirely diaphragmatic. There is no weakness in the arms but absolute paralysis of the intercostals and of all the muscles below them. The sphincters are completely paralysed and there are very large bedsores. The reflexes are completely absent. He has no pain except a little in the abdomen when he is rolled over.

Though I am glad to say we have not yet had to break the good record that I told you of in the matter of amputations, yet we have had many patients sent to us who have lost a limb in the field hospitals, where of course most of such operations are chiefly called for. I wonder what arrangements have been made for seeing that each stump is fitted with that particular appliance which is most suited to the needs of the owner. The maimed of our heterogeneous army belong to very varied classes and walks in life, and the appliance which is the most suitable for a farm or factory labourer is sometimes the most unsuitable for a clerk or policeman. Even in times of peace one frequently sees a bad selection made, and as the future ability of each patient to help himself and others depends so much upon the adaptability of the appliance provided for the particular end which is in view there ought to be a really good selection based, not upon the question of expense—that ought not to arise and I believe does not—but upon the question of the particular requirements of the particular case.

Deelfontein.

## THE IMPERIAL YEOMANRY BASE HOSPITAL.

BY L. V. CARGILL, F.R.C.S.,
OPHTHALMIC SURGEON TO THE HOSPITAL.

There have been the following changes in the staff. Mr. A. D. Fripp, Mr. Raymond Johnson, and Dr. H. W. Saunders have left for England. Mr. W. Turner and Dr. L. E. C. Handson, with Mr. E. N. Thornton as dresser, have gone to the Mackenzie Farm Branch at Cape Town, where Mr. Turner is acting as principal medical officer. The medical side consists of Dr. J. W. Washbourn, senior consulting physician, and Dr. A. Elliot, Dr. G. E. Richmond, Dr. C. W. Breeks, and Dr. Barclay Black. Mr. Hamilton A. Ballance has become the senior consulting surgeon, the other surgeons being Dr. J. B. Christopherson, Mr. W. C. G. Ashdowne, Dr. A. P. Parker, and Dr. H. W. Bruce. The writer still remains in charge of the ophthalmic department and Mr. Hall-Edwards in charge of the x-ray department. The dressers are Mr. J. Atkins, Mr. A. de V. Blathwayt, Mr. A. Pearson, Mr. A. C. Ransford, Mr. O. Richards, Mr. Hawkins, and Mr. Sells Dr. Elliot and Dr. Parker, who have been away on sick leave, have returned to duty. Mr. D. J. Greenfield, one of the dressers, who has had enteric fever, has been away on sick leave to Lady Gifford's convalescent home at Norval's Pont, and is returning to England. Of the nursing staff Sisters Brereton and Leggatt have gone to the Pretoria branch, and Sisters Stephenson, Cable, and Cooper to the Mackenzie Farm Branch, Cape Town.

Under the supervision of Mr. Hall-Edwards electric light has now been installed in the cruciform building containing the operating theatre and surgical store, the x-ray and photographic rooms, and the surgery. It is proving a great boon. The dynamo is worked by a four horse-power oil-engine. The Russian bath which has been opened in the laundry building is a great success and is largely patronised. It is managed by Hale-Smith, the chief masseur.

There are 770 patients in hospital, 38 of whom are officers and nearly one-half of the total number belong to the Imperial Yeomanry. Patients are being received and discharged daily, and a week ago No. 4 ambulance train brought 17 officers and 95 men from Wynberg, most of whom came from General Clements's force. They were nearly all surgical cases. Judging from the few cases which we now have of enteric fever and dysentery, the epidemic has completely subsided. The majority of the medical cases now admitted consist of various forms of rheumatism. As a rule, the rheumatism takes a subacute form which is not readily amenable to treatment. Presumably, its prevalence is due to the weather which, contrary to the general rule, has been not only cold but exceptionally damp, in spite of this being the dry season for up-country. In addition to rheumatism a not inconsiderable number of cases of malaria have been admitted, the patients either being old sufferers from malaria or having contracted the disease north of Bloemfontein and Kimberley. One of the wardmaids has developed measles, but from what source has not at present been determined. There have been no further cases of scarlet fever. Among the enteric cases there have been several cases of typhlitis, usually recrudescences of a former attack. A case recently operated on by Mr. Ballance is now doing well.

Dr. Washbourn reports that musk has been of great value in the treatment of certain cases of enteric fever. In a case in which the patient was comatose and almost pulseless rapid improvement ensued upon the administration of musk in five-grain doses every four hours. The improvement was maintained and the patient is now convalescent. In another case of enteric fever with persistent pyrexia continuing after the other symptoms had subsided the administration of salol caused the temperature to return to normal in a couple of days. It would appear that the pyrexia was due to putrefactive changes occurring in the intestinal canal which were prevented by the salol.

In addition to the operations performed on wounded men there has been a fair amount of ordinary civil surgery lately. During the last week Mr. Ballance has operated on two cases of mastoid disease following recent otitis media. In one case the patient was suffering from enteric fever and in the other from scurvy. There are in hospital a considerable number of cases of compound fracture of the lower limb with extensive and troublesome necrosis needing repeated operations.

The weather here has been very variable. A few days have been genial, but other days have been bitterly cold, windy, and gloomy, and we have had snow and hail as well as rain. Fortunately last Wednesday was a fine day for the athletic sports which had been chiefly organised by Captain Mosley Leigh of the Cheshire Yeomanry. They proved a great relief to the monotony of camp life and were immensely appreciated by all.

We are expecting the Hospital Commission here Thursday, and our chaplain, the Rev. J. Blackbourne, has

gone to Cape Town to give evidence before them regarding his experiences as chaplain to the Sixth Division on the march from Modder River to Bloemfontein.

Deelfontein, August 27th.

## THE PLAGUE IN GLASGOW.

BETWEEN Sept. 10th and Sept. 14th no fresh cases of plague were announced in Glasgow. On Saturday, Sept. 15th, however, one fresh case was officially announced—namely, that of a ward-cleaner in the Belvidere Hospital. The patient had been inoculated and the disease has only shown itself in a very mild form. The total number of cases on the morning of Sept. 15th was 17, suspected cases one, persons under observation 115.

On Sept. 17th, however, five additional cases were reported. Four of them occurred in one family and the fifth was the wife of a worker in the Belvidere Hospital. The family were known to have been in contact with previous plague cases. The figures, therefore, for Sept. 17th were: total number of cases, 22; suspected cases, one; persons under observation, 115.

Up to the night of Thursday, Sept. 20th, no further cases had been reported, so that the figures stood thus: total number of cases, 21; suspected cases, one; persons under observation, 105. The decrease of one in the number of cases is due to the death of one of the family reported as plague-stricken on Sept. 17th. Thus five deaths in all have occurred—namely, two in the Belvidere Hospital and three outside.

The Glasgow magistrates held a private meeting on Sept. 12th and decided to issue a strongly-worded appeal through the Roman Catholic clergy to discontinue the holding of wakes as the authorities are convinced that the holding of the Bogan wake in Thistle-street was the main cause of the spread of the disease. The Roman Catholic clergy, while deploring the free use of alcoholic drink at wakes among the poorer classes of the community, yet wish to bring out the fact that the watching of the dead among the middle classes is a very solemn function. Undoubtedly this is so and reverence for the dead is not a thing to be regarded lightly. Reverence for the dead, however, must give way to regard for the living and we cannot but think that the authorities of the Roman Catholic Church, a body which possesses in a very large degree the quality of common sense, will see the force of this statement. It must further be remembered that the Glasgow Parliamentary powers prohibit the holding of wakes over the body of any person who has died from infectious disease and that the occupiers of houses who permit such wakes to take place, as well as all persons knowingly attending such wakes, are liable to a penalty not exceeding 40*s*.

Professor Muir, the professor of pathology in the University of Glasgow, has laid before the Corporation of Glasgow a report upon the "Bacteriology and Pathology of the Cases of Suspected Plague in Belvidere Hospital." The report states that the bacillus found in the cases examined was proved to be both structurally and culturally identical with the bacillus of bubonic plague, while the pathogenic results of the plague bacillus were reproduced in animals by inoculation with the pure cultures obtained from the human subject.

Nine of the cases were examined bacteriologically, fluid being obtained by puncture of the affected glands. This fluid was examined both microscopically and by cultures. In four cases the bacillus was found and cultivated. In one case (Mrs. Malloy) a few degenerated plague bacilli were found, but no cultures were obtained. Dr. J. C. McClure had, however, two days previously to Professor Muir's examination obtained pure cultures, and, says Professor Muir, "the negative results obtained by me were in all probability due to the fact that the disease was in process of cure and that the bacilli were dying out." Four other cases were examined with negative results, but they were getting well. The post-mortem examination of the body of Patrick Malloy revealed that the lymphatic glands were almost universally affected and contained enormous numbers of bacilli. Professor Muir concludes by saying that up to the date of his report, Sept. 17th, five cases had been proved by bacteriological methods to have suffered from bubonic plague, and that one of the patients died from that disease.

We publish additional notes from Dr. J. Brownlee and Dr. J. Campbell McClure as to the

### CLINICAL ASPECTS OF THE CASES OF PLAGUE.

During the last fortnight several points of interest in connexion with the present outbreak of plague have arisen. The persons originally admitted, with one exception are now out of danger. The exception is that of the patient Bogan, whose case was reported in THE LANCET of Sept. 15th, p. 827, and who is still suffering from secondary septic infection.

The chief points of interest are those dealing with treatment and administration. With regard to the former, we are able to report one very interesting case, showing the result of the use of Yersin's anti-plague serum. The case was suitable in many ways as a test of the value of the treatment. The patient came under care in the early stage of illness (within 30 hours of its inception). He was very acutely ill, resembling closely the patient formerly reported whose death occurred in the hospital. The seat of the bubo was in the axilla, a situation much more dangerous to life than that of the groin. Four hours after admission 40 cubic centimetres of the serum were injected, half intravenously and half subcutaneously, with the result that the temperature fell 4° F. in six hours and that there was in the like time a very marked diminution in the swelling round the bubo, while the tenderness was greatly reduced and in the course of the day passed almost completely away. Two days later the patient felt almost well and the pain in the bubo had disappeared.

The following is a report of the case of Charles M., aged 30 years, who was admitted to the Belvidere Hospital on Sept. 9th. Association with other cases has not been traced and therefore the period of incubation is unknown. The history of the illness obtained from his friends and afterwards verified by himself was to the effect that for about a week before his admission to the hospital he had suffered from moderately severe headache and slight malaise, but he continued at his work until the morning of Sept. 8th, when he had a rigor with increased severity of the headache and sickness, although vomiting was absent. By noon he was unconscious, and he was delirious all night and very violent.

On admission the patient was evidently extremely ill. His face was of an ashy colour with a more marked ring of pallor round the mouth. The conjunctivæ were slightly injected and the pupils were contracted in contrast to the more common dilatation observed in the other cases. The tongue was moist with a white fur on the dorsum, but not markedly injected. The temperature was 105·8° F., the pulse was 134, and the respirations were 40. The pulse was soft and compressible but full. There was no evidence that the patient was in the least conscious of his surroundings. When left alone he tossed restlessly in bed, but betrayed considerable anxiety in his face. On being handled he resisted so strongly that it was impossible for the nurses to wash him. This resistance was extremely marked if the palpation of his left axilla was attempted. In this situation a group of glands was found which were enlarged and acutely painful. (It is to be noted here that the movements of resistance made in opposition to the examination of this bubo resembled those of a person conscious of his actions and not the purposeless movements usually made in the delirium of typhus or enteric fever.) The only bubo found was in the left axilla; elsewhere, though the glands were slightly enlarged the enlargement was no more than is often met with in healthy persons. The other organs on examination showed nothing worthy of note. At 12 midnight 20 cubic centimetres of serum (Yersin's) were injected into one of the brachial veins and a like quantity into the subcutaneous tissue of the abdomen. This was done with considerable difficulty owing to the struggles of the patient. At the end of six hours it was seen that the patient had had a light sweat and that the temperature had fallen four degrees. The pulse-rate was reduced to 108 and the respirations had fallen to 34. The pain in the axilla was markedly lessened, and the surrounding œdema was much less. By the evening the glands could be palpated without undue resistance. A puncture for the purpose of completing the diagnosis was performed with the result that the clinical diagnosis was confirmed microscopically. By next day the cultures made at the same time showed typical growths of the bacillus pestis. On this

day the temperature was throughout 100° and the pulse ranged from 64 to 76. The patient felt quite well and desired to get up. On questioning him it was found that he remembered nothing from mid-day on Saturday (Sept. 8th) till the evening of Monday (the 10th) when he found himself in the hospital. Since the latter date the improvement has been constant with the exception of a rise of temperature to 101° on the evening of the 14th, associated with a slight recrudescence in tenderness of the glands in the left axilla which subsided on the next day. The pulse, however, is still weak and the heart-sounds are somewhat toneless. For the past 24 hours he has experienced some discomfort from pain in both knee-joints and in the left thigh, due in all probability to the serum injected on the 9th.

From the administrative point of view there can be no doubt that the mild cases of plague such as have been observed among those who had been in contact with the infected persons, either attending the "wakes" held over the dead bodies or otherwise, and who were subsequently under medical observation in the reception houses, are the most interesting. For it is evident that if these persons are even slightly infective their rigid isolation is a matter of the greatest importance to the community. Up to the present time we have received from the reception houses seven persons, of whom six seemed to be suffering from very slight attacks of plague, so slight that did they come under observation without a definite history of contact they would, apart from a bacteriological examination, be quite unrecognisable. The importance of the matter is further enhanced when it is considered that in these cases the buboes have been so small that to put a needle into the substance of the gland has been a most difficult matter. The general symptoms which these persons have exhibited have been as follows. In the onset there has been headache and malaise associated with sickness, while vomiting has been only occasional. The temperature has been only slightly raised—rarely above 100° F. and sometimes not above 99·6°; the pulse has been only slightly quickened and the rapidity of the respirations has not been markedly altered. The face has been heavy and drowsy-looking, the eyes have been injected, and the tongue has been furred. In fact, in general there has been an appearance of illness in the aspect of the patient which has been quite out of proportion to the severity of the symptoms. This look of illness usually persists for several days after the symptoms have subsided. The seat of the buboes in the seven cases has been twice in the left axilla, three times in the submaxillary glands, once in the anterior cervical chain, and once in the glands of the posterior triangle of the neck. The glands have been enlarged, with some peri-glandular infiltration and in one case reddening of the skin. Tenderness has always been present, though not so markedly as in the more severe cases of typical plague, and this tenderness has usually appeared on the second day of illness; it subsides after two or three days, though the swelling of the glands may not be wholly absent even after a fortnight. The clinical picture is fairly constant, though, as before remarked, the illness is not of a severity to be readily diagnosed unless with a definite history of plague contact.

We have up to the present been somewhat diffident in publishing reports of these cases because in only one case was it possible to make sure that our hypodermic needle had reached the gland, and in that instance the cultures gave no growth. But at the end of last week a wardmaid employed in the pavilion used for the isolation of the plague patients, and who had received a protective inoculation of 10 cubic centimetres of Yersin's serum exactly 10 days previously, developed an illness in all points exactly resembling that which we had before observed in the six patients received from the reception houses. It is only fair to state that owing to the fact that the serum arrived a week after the outbreak of plague amongst us the patient had been exposed to infection for that time without protective inoculation. In this case the buboes were in the posterior cervical region, so that their puncture was rendered more easy on account of the resistant deeper tissue which lay subjacent and did not involve the same risk as in the other cases where the glands affected lay over the main blood-vessels. From this case we have obtained typical cultures of the plague bacillus. We report in full this case and that of a boy admitted earlier in the outbreak as illustrative of the milder forms of the disease.

The patient, Archibald D., aged 18 years, was at the wake of Christina M. on the night of August 21st and was removed to the reception house on the day succeeding to the first discovery of plague in Glasgow. On the evening of August 28th he was seen by one of us on account of his having been taken ill. The patient was very drowsy, so much so that he manifested no reflex on touching the conjunctiva with the finger. There seemed to be no suspicion that this was due to alcohol. Headache, sickness, and vomiting had been marked and severe just before arrival, but had temporarily subsided. The temperature was normal, and the pulse was 70. All the glands of his body which were accessible to palpation were examined without anything abnormal being discovered. Next morning the patient was somewhat better, but he was kept in bed. In the afternoon a recurrence of the headache and vomiting took place. The submaxillary glands in the left side were complained of and found to be enlarged. The temperature was 99·6° F. He was straightway sent to hospital.

On admission the patient had that heavy and obfuscated look which has been already described in such cases, with injection of the conjunctivæ and slight dilatation of the pupils. The submaxillary glands were considerably enlarged and painful on palpation. Next morning the temperature was 99°, at which elevation it remained all day, but a consistent normal temperature was not maintained till the seventh day of the illness. The pulse on admission was 72 and had on the latter date declined in rate to 50, while the respiration rates were respectively 24 and 20.

The tenderness of the glands persisted for about three days, when it gradually subsided, but the swelling has not even at the date of writing (Sept. 18th) completely disappeared. The aspect of illness was more marked and lasted longer than would have been expected from the local conditions had the latter been due to ordinary causes. As possible causes of the condition which were definitely excluded may be mentioned caries of the teeth, faucial catarrh, and nose or ear mischief. Puncture of the gland was attempted only once, as it immediately overlay the deep vessels of the neck, and the culture proved sterile. It is, however, open to doubt whether the needle actually penetrated the substance of the gland.

H. R., aged 21 years, was a wardmaid in the wards at the Belvidere Hospital reserved for plague. As the patient was exposed continually to infection for the space of 15 days before developing the disease it is impossible to name the period of incubation. On Sept. 3rd, as a prophylactic measure, 10 cubic centimetres of Yersin's serum were injected subcutaneously. This produced none of the effects often resulting from it, such as urticaria or articular pains. On the 13th headache and pain in the back were complained of and nausea was also present, but there was no vomiting. The patient, however, felt very unwell. On the 14th the headache and malaise still continued and in addition tenderness and stiffness in the back of the neck were complained of. The eyes were slightly injected and the face was flushed and its expression heavy. The tongue was slightly furred but was otherwise normal. Neither diarrhœa nor constipation was present. The temperature was normal and the pulse showed nothing noteworthy. Behind the ears, in the posterior triangle of the neck, there was on each side a markedly enlarged lymphatic gland—that on the left side being of about the size of an almond and that on the right side of the size of a bean. Puncture was made into the gland of the left side and cover-glass films and cultures were made. These showed a bacillus morphologically indistinguishable from the bacillus pestis. By the 15th the tenderness of the glands had subsided and since that date they have been decreasing in size. The patient is now to all intents and purposes well.

In conclusion, we may once again remark that these persons probably belong to a class who represent a real danger to the community, for it cannot be supposed that because of the mildness of the attack the sufferers are not infective. All our experience of other infective diseases points to the conclusion that it is largely by means of such cases that the infection is scattered broadcast and the fact that in so many of the outbreaks of plague in the East there has existed for a considerable time prior to the serious epidemic an amount of slight illness of an apparently benign nature but which seemed afterwards to take on a malignant character ought to justify the most stringent observation of all persons in whom even the slightest suspicion of the presence of the malady can be assumed.

It must be noted that of the seven cases of benign plague

here discussed one is a case occurring in the hospital, while the other six have been among persons under medical observation in the reception houses of the city; that is, of the 100 persons removed for observation in the reception houses six persons have developed a form of the disease which would probably greatly endanger the safety of the community, but which, except for direct medical supervision of the sufferers, would most probably never have come to the cognisance of the health authorities.

As we go to press we learn by telegram that four "indirect contacts," a ward-cleaner who had been inoculated, and the wife of a collector of infected clothing have sickened.

---

A statement was made in our issue of Sept. 8th (p. 758) that the area described by Dr. Chalmers on the south side of the river and surrounding Thistle-street should be deemed infected. In reality the area was so deliminated as a special cleansing area, and not because it was regarded as a wholly infected area.

## THE PLAGUE IN LONDON DURING THE REIGN OF ELIZABETH.

THE records of the Corporation of the City of London contain a number of letters which are of considerable interest in showing the state of the City during the visitation of the plague in the reign of Elizabeth.

On June 7th, 1580, the Lord Mayor wrote to the Lord Treasurer, Lord Burleigh, suggesting that, as the plague was at the time raging in Lisbon, he should be authorised to take precautions on the arrival of ships from that port and for the prevention of the spread of the infection in London. Lord Burleigh replied authorising him to prevent the lodging of merchants or seamen in the City and the suburbs, and to prevent a discharge of their goods until they had had some time for airing. He also suggested that there should be a conference of the officers of the port to suggest measures for the prevention of the infection.

Later in the same year the Lord Mayor wrote to the Mayor and Jurats of Rye, saying that as the plague was raging in that port he had received commands from the Queen's Council to stay all ships and merchandise from being brought to the City until they had been aired and he requested that the inhabitants of Rye might be charged not to come to the City or send goods by land so long as the plague remained there. The Lord Mayor also requested the Queen's Council to redress those things which were found to be dangerous in spreading the infection "and otherwise drawing God's wrath and plague upon the City," and enumerated amongst the exciting causes which were likely to affect this, "the erecting and frequenting of infamous houses out of (i.e., beyond) the liberties and jurisdiction of the City,"—and "the drawing of the people from the service of God and honest exercises to unchaste plays." Regulations which were drawn up for the purpose of staying the plague included amongst other things rules for the conduct of the inmates of places pretending exemption, restraining the building of small tenements, and the turning of great houses into small habitations by foreigners, the prevention of any increase in the number of buildings, especially about Charterhouse, Mile End, and St. Catherine's, and of "the pestering of exempt places with strangers and foreigners," and "the number of strangers in and about London of no Church," the haunting of plays beyond the liberties and the slaughter of cattle within or near the City.

In the month of September, 1581, their lordships also informed the City authorities that the Queen had been informed that the increase of the plague was due to the fact that the orders passed with respect to the persons infected were not being carried out. In consequence of this the Queen had been obliged to remove further off and to adjourn the law term, and if improvement did not take place the term, it was threatened, would be held elsewhere.

In April, 1582, the Lords of the Council gave orders to restrain burials in St. Paul's Cathedral because the interments were so shallow and the churchyard so crowded that scarcely any grave could be made without corpses being laid open. The number of parishes which were allowed to use St. Paul's churchyard was therefore reduced from 23 to 13.[1] The order, however, it was distinctly stated, was not intended to prevent any person of honour or worship being buried there, but only the pestering of the churchyard with whole parishes.

In October, 1582, the Queen issued orders prohibiting any merchants or other persons from the City whose houses had been infected from resorting to or sending to Hertford, Ware, Hoddesdon, or other places near Hertford, any sort of merchandise, food, or such like. At this time it appears that the law courts were sitting at Hertford.

In January, 1583, the Lord Mayor was required by the Council to see what inns and ale-houses had been infected during the two months before the issue of the order, and to have a list made of these places. The Lord Mayor accordingly had such a catalogue made and printed "for everyone that liked to buy and keep for his instruction." Lord Burleigh, in acknowledging the receipt of this catalogue, said that they had had a similar one from Westminster prepared by the Bailiff of that city. It was his opinion that the catalogue prepared by his lordship was somewhat too long and he desired the Lord Mayor to send for the Bailiff of Westminster and see how short a catalogue might be made to be published, and that this new list, when agreed on, should be sent to him for inspection.

On Jan. 15th the Lord Treasurer returned the corrected catalogue of the infected houses, in order that steps might be taken to increase its brevity.

By the month of April, 1583, the infection had much increased and the Queen commanded that infected houses should be shut up and provision made to feed sick persons and to prevent them from going out, that infected houses should be marked, and the streets thoroughly cleansed. Her Majesty expressed surprise that no hospital had been built outside the City to which infected people might be removed, although other cities of less great antiquity, fame, wealth, and reputation had provided themselves with such places. The Lord Mayor, in a letter written on May 3rd, complained of the great inconveniences caused by assemblies of the people at plays, bear-baiting, and profane spectacles at the theatre and such like places. These being beyond the jurisdiction of the City were not under the control of the Lord Mayor, who expressed a wish that the Lords of the Council might redress the danger. It does not appear, however, that this request was immediately granted.

[1] The total number of parishes in the city of London was 120.

## ASYLUM REPORTS.

*Cumberland and Westmoreland Asylum (Annual Report for 1899).*—The average number of patients in the institution was 642 and comprised 335 men and 307 women. During the year 163 patients were admitted, 96 of these being men and 70 women. Of these, 35 in all—viz., 22 males and 13 females—were not first admissions. Dr. W. F. Farquharson, the medical superintendent, states in his report that of the patients admitted 148 were chargeable to the rates and 18 were private patients. "The admissions included two cases of congenital imbecility, five cases of epilepsy, seven cases of general paralysis, 10 patients who were over 70 years of age, and seven chronic cases transferred from other asylums. In 30 cases the attack had lasted more than a year before the patient was brought to the asylum. The great majority of the cases just enumerated were incurable." 35 of the patients admitted had previously been under treatment in the asylum and 23 of these had formerly been discharged recovered. "More than one-half of the patients admitted were in a feeble state of health; 15 of these were on admission in an extremely weak and exhausted state, and several of them died very shortly after being brought to the asylum. ..... 47 of the patients admitted had suicidal tendencies; 18 of these had actually attempted suicide before admission." In many of the cases admitted no definite cause of the attack could be ascertained. "Where such causes were known those of a physical nature predominated, as is usual." Hereditary predisposition to insanity was ascertained to exist in 51 cases, or 30·7 per cent., of the admissions, while intemperance in drink was the cause in 25 cases, or 15 per cent. During the year there were 91 patients discharged as recovered, the highest number of such discharges per annum in the history of the asylum and constituting 14 per cent. of the average number resident. 31 patients were discharged as relieved, and of these 24 were removed to the workhouse as no longer requiring asylum treatment. The number of deaths during the year

amounted to 44—viz., 24 men and 20 women, or 6 8 per cent. of the average number resident. Eight of the patients who died were over 70 years of age. One patient, aged 87 years, was admitted in a very weak state and died in three weeks; one patient was admitted dying from consumption and he only survived a week. All the causes of death were ascertained or verified by post-mortem examination. Of the deaths two were due to general paralysis of the insane, three to renal disease, five to senile decay, six to cardiac disease, and 17 to tuberculosis. Dr. Farquharson observes that "phthisis unfortunately is a disease very prevalent in asylums ..... its contagious nature is now clearly recognised, and large asylums afford great opportunities for the spread of the disease." Full stress is laid on the importance of the recommendation made at a recent meeting of the Medico-Psychological Association, that in connexion with each asylum there should be erected a sanatorium, built it may be of wood, to which all phthisical patients could be removed for treatment as far as possible on open-air principles. It is pointed out that at a date not far remote the further enlargement of the asylum will become necessary, and if in the first place a cheap sanatorium for phthisical patients were erected it would for a considerable time relieve the pressure on the accommodation in the present buildings. In the early part of the year one male patient and three female patients suffered from facial erysipelas. No casualties of any note occurred during the year with the exception of two cases of accidental fracture of bones, both in aged females. Much of the drainage of the asylum has been altered and rendered efficient. Owing to the fields used for irrigation by the asylum sewage having become sewage-logged, and complaints received of poisoning of cattle, it has been decided to adopt the system of the septic tank with subsequent filtration of the sewage through bacteria beds, a method known to be very satisfactory. The arrangements for dealing with an outbreak of fire have been improved upon, electric fire alarms have been installed throughout the building with an indicator in the entrance hall, new hose has been purchased, and periodic fire-drill of the attendants has been carried out.

# Public Health and Poor Law.

## LOCAL GOVERNMENT DEPARTMENT.

### REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

*On Enteric Fever in the Urban District of Coleford (Gloucestershire) and in the Surrounding Rural District of West Dean*, by Dr. W. W. E. FLETCHER.[1]—Dr. Fletcher reports upon an outbreak of enteric fever in the small town of Coleford which, as he and Dr. Peter Buchanan, the medical officer of health of that place, had no difficulty in showing, was attributable to a particular milk service. In 1899 there occurred, after some months in which no enteric fever was reported in the district, a period of five weeks, from July 20th onward, in which no less than 74 persons were attacked in Coleford and its neighbourhood. Every one of the 19 Coleford houses invaded during this period were served with milk by a Mr. X., one, and by no means the principal, of the numerous vendors of milk in the place. And Mr. X.'s milk appears also to have been consumed by certain of the persons living in West Dean, just outside Coleford, who were attacked during the five weeks in question. From the end of this five weeks to December, 1899, a few scattered cases, principally secondary cases in houses invaded during the epidemic period, occurred in each month, but the disease did not again assume epidemic proportions. The cause of the milk becoming infectious is not quite certain; Dr. Buchanan saw reason to suspect that the milk-cans were washed with well water liable to privy contamination, but apparently no specific pollution which could account for the epidemic was traced to this well water. Dr. Fletcher also discovered that one of the milkers was suffering at the beginning of July from mild illness, not enough to keep him from work, which conceivably was enteric fever. On the latter assumption the dates and other circumstances were consistent with a theory that this milker had in some way or other infected the milk. As in most milk outbreaks, the incidence was chiefly on the children and on female adults. Out of the 74 cases 48 were females, and as many as 34 were under 15 years of age. The diagnosis of enteric fever was controlled in some instances by the serum test. This test (dilution not stated) in the case of the milker suspected of having caused the whole mischief had a "negative result."

*On the Sanitary Circumstances and Administration of the Urban Districts of Bilston and Coseley and upon a Prevalence of Enteric Fever therein*,[2] by Dr. L. W. DARRA MAIR.—Coseley and Bilston are two urban districts in the "Black Country" and are certainly no better in sanitary condition than their neighbours. In Dr. Mair's report, as we have often noticed in other official reports on these Staffordshire towns, the insanitary state of the surroundings of dwellings is strongly insisted on. The objectionable common yard at the back of dwellings, traversed by faulty gutters, unpaved, with large middens and associated privies which inevitably lead to excremental pollution of the soil, abound in both these places. Some of these middens have as large an area as from 60 to 80 square feet and are sunk four feet below the surface. Both districts in question contain a large number of dwellings for miners and artisans, put up haphazard several years ago without supervision by responsible authorities. As a result dilapidations are common; houses are frequently damp, having often been built without damp courses on clay soil; very frequently they have been erected on coal-pit débris or on other made ground, while in addition subsidences due to mining have caused, and still occasionally bring about, tilting and cracking of dwellings. To secure improvement of such houses and their surroundings is by no means an easy task for a local authority, particularly where the owners are keen in opposition and where, as so often is the case, the tenants in order to avoid increased rents support the owner in leaving things alone. Nevertheless, it is clear from this report that very much more courage should be shown by each of the district councils in question. It is not certain that they are taking sufficient trouble even now with new buildings, and thus they may be casting a heavy burden on their successors in future years. The facts which Dr. Mair gives as to the recent prevalence of typhoid fever illustrate the close connexion between the sundry unwholesome conditions of dwelling-houses and the endemic maintenance of this disease. A variety of useful recommendations are attached to the report. Among them one of the most pressing is obviously reorganisation and increase of the sanitary staff in both places. Dr. Mair indicates that each district suffers from lack of sufficient personal inspection by its medical officer of health, who in each instance is in private practice and is paid a comparatively small salary for his official work. It is a great pity that owing to anxiety to respect local prejudice all public authorities now seem to fight so shy of "combined districts." How much good might not be done by one capable health officer, sufficiently paid, and appointed, say, for half-a-dozen of the contiguous urban districts in the Black Country?

*Memorandum on a Brief Visit to Pontypridd Urban District with Reference to a Fatal Prevalence of Diphtheria therein*,[3] by Dr. L. W. DARRA MAIR.—Pontypridd urban district is of wide area—2560 acres—and comprises several large groups of population that have recently come to inhabit the mountainous districts about the rivers Rhondda and Taff in South Wales. Altogether its population is estimated at 38,900. For several years diphtheria has been widely prevalent throughout the entire district, while now and again its incidence has been exceptionally severe on communities in particular parts of it. In 1899 as many as 227 cases of diphtheria were notified, and from Jan. 1st to March 10th, 1900, there were no less than 108 notifications of this disease. Dr. Mair's memorandum, no doubt on account of the urgency of the case, deals wholly with preventive measures, which seem to have been very badly neglected at Pontypridd. Inquiry into the circumstances under which diphtheria has in late years so severely attacked certain of these valleys in South Wales is nevertheless much to be desired. A comprehensive investigation of the "epidemiological" sort into this subject might lead to valuable additions to our knowledge of the natural history of diphtheria.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6500 births and 4046 deaths were registered during the week ending Sept. 15th. The annual rate of mortality in these towns, which had been 21·7 and 19·6 per 1000 in the two preceding weeks, further declined last week to 18·2. In London the death-rate was 16·7 per 1000, while it averaged 19·1 in the 32 provincial towns. The lowest death-rates in these towns were 9·1 in Norwich, 10·7 in Cardiff, 11·1 in Bradford, and 11·4 in Halifax; the highest rates were 23·2 in Liverpool, 23·7 in Swansea, 25·4 in Manchester and in Preston, and 26·8 in Sheffield. The 4046 deaths in these towns included 879 which were referred to the principal zymotic diseases, against 1422 and 1143 in the two preceding weeks; of these 575 resulted from diarrhœa, 111 from whooping-cough, 73 from "fever" (principally enteric), 57 from diphtheria, 40 from measles, 22 from scarlet fever, and one from small-pox. The lowest zymotic death-rates last week occurred in Oldham, Huddersfield, Halifax, and Bradford; and the highest rates in Leicester, Manchester, Preston, and Hull. The greatest mortality from scarlet fever occurred in Sunderland; from whooping-cough in Croydon, Derby, and Gateshead; from "fever" in Portsmouth and Sunderland; and from diarrhœa in Leicester, Manchester, Preston, and Hull. The mortality from measles showed no marked excess in any of the 33 towns. The 57 deaths from diphtheria included 17 in London, nine in Leicester, six in Bristol, five in Salford, and four in Sheffield. One fatal case of small-pox was registered last week in Liverpool, but not one in any other of the 33 large towns; and only three small-pox patients were under treatment on Saturday last, Sept. 15th, in the Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1753, against 1702 and 1736 on the two preceding Saturdays; 243 new cases were admitted during the week, against 140, 176, and 213 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 138 and 124 in the two preceding weeks, rose again last week to 161, and were 12 above the corrected average. The causes of 45, or 1·1 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Leicester, Salford, Bradford, Newcastle, and in 13 other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Blackburn, Halifax, and Sheffield.

### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined from 17·9 to 17·5 per 1000 in the three preceding weeks, rose again to 18·9 during the week ending Sept. 15th, and showed an exces of 0·7 per 1000 over the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 15·2 in Leith and 15·8 in Dundee to 22·3 in Greenock and 32·0 in Perth. The 584 deaths in these towns included 54 which were referred to diarrhœa, 21 to whooping-cough, seven to scarlet fever, seven to "fever" (including one death from bubonic plague), six to diphtheria, two to measles, and one to small-pox. In all 98 deaths resulted from these principal zymotic diseases, against numbers decreasing from 108 to 83 in the four preceding weeks. These 98 deaths were equal to an annual rate of 3·2 per 1000, which was 0·7 below the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of diarrhœa, which had been 54 and 42 in the two preceding weeks, rose again last week to 54, of which 21 occurred in Glasgow, 11 in Edinburgh, seven in Dundee, five in Leith, four in Aberdeen, and four in Greenock. The deaths from whooping-cough, which had been 25 and 21 in the two preceding weeks, were again 21 last week and included 16 in Glasgow and two in Greenock. The fatal cases of scarlet fever, which had been five, five, and four in the three preceding weeks, rose again last week to seven, of which six were registered in Glasgow. The deaths referred to different forms of "fever," which had declined from eight to four in the three preceding weeks, rose again last week to seven, of which two occurred in Paisley, two in Greenock, and one (the fatal case of bubonic plague), in Glasgow. The six deaths from diphtheria showed a slight increase over recent weekly numbers, and included two in Edinburgh and two in Aberdeen. The fatal case of small-pox was registered in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 58 and 79 in the two preceding weeks, declined again last week to 70, but slightly exceeded the number in the corresponding period of last year. The causes of 29, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 27·0, 26·7, and 22·2 per 1000 in the three preceding weeks, rose again to 24·8 during the week ending Sept. 15th. During the past four weeks the death-rate in the city has averaged 25·2 per 1000, the rate during the same period being 18·5 in London and 16·7 in Edinburgh. The 166 deaths belonging to Dublin registered during the week under notice were 17 in excess of the number in the preceding week, and included 44 which were referred to the principal zymotic diseases, against 40 and 26 in the two preceding weeks; of these 27 resulted from diarrhœa, seven from whooping-cough, seven from "fever" (principally enteric), two from diphtheria, one from scarlet fever, and not one either from small-pox or measles. These 44 deaths were equal to an annual rate of 6·6 per 1000, the zymotic death-rate during the same period being 3·2 in London and 2·8 in Edinburgh. The fatal cases of diarrhœa, which had been 32 and 20 in the two preceding weeks, rose again to 27 last week. The deaths from whooping-cough, which had been four and five in the two preceding weeks, further rose last week to seven. The seven deaths referred to different forms of "fever" showed a marked increase over recent weekly numbers. The 166 deaths in Dublin last week included 46 of infants under one year of age and 28 of persons aged upwards of 60 years; the seven deaths of infants exceeded the number recorded in the preceding week, while those of elderly persons showed a decline. Three inquest cases and four deaths from violence were registered, and the causes of eight, or nearly 5 per cent., of the deaths in the city last week were not certified.

## THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—

Staff Surgeon: E. P. Mourilyan to the *Severn*. Surgeons: W. J. Stitt to the *Australia* and E. H. McSherry has been appointed to the *Phœbe*.

Deputy Inspector-General of Hospitals and Fleets Henry Charles Woods, M.V.O., M.D., has been promoted to the rank of Inspector-General of Hospitals and Fleets in Her Majesty's Fleet.

### ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Frederick Rowland Barker retires on retired pay.

Lieutenant-Colonel J. L. Peyton succeeds Lieutenant-Colonel Hughes as P.M.O., Salisbury Plain. Lieutenant-Colonel R. V. Ash, retired list, is appointed to the medical charge of the troops at Fleetwood.

### INDIA AND THE INDIAN MEDICAL SERVICES.

Lieutenant-Colonel Thomas Stephenson Weir, Bombay Establishment, to be Colonel.

### VOLUNTEER CORPS.

*Artillery:* 4th Lancashire: Surgeon-Lieutenant W. McClelland to be Surgeon-Captain. *Royal Engineers;* 1st Cheshire: Surgeon-Lieutenant W. Lawton to be Surgeon-Captain. *Rifle:* 4th (Perthshire) Volunteer Battalion the Black Watch (Royal Highlanders): Surgeon-Captain A. Thom resigns his commission. 2nd Volunteer Battalion the Sherwood Foresters (Derbyshire Regiment): Surgeon-Lieutenant-Colonel E. M. Wrench retires under paragraph 111 Volunteer Regulations, with permission to retain his rank and to wear the uniform of the battalion on retirement.

### TRANSVAAL AND CHINA WAR NOTES.

The P. and O. steamer *China*, which arrived in Plymouth

on Sept. 9th, brought to the Royal Naval Hospital, Plymouth, 16 wounded sailors and marines from China. Most of the men formed part of Admiral Seymour's relief column, while the others took part in the fighting at Tientsin. The majority of the wounds were caused by Mauser and Mannlicher bullets. The invalids were conveyed to the Royal Naval Hospital, Plymouth.

Mr. J. Paul Bush, M.R.C.S., surgeon to the Bristol Royal Infirmary, and formerly in charge of the Princess Christian Hospital, arrived in Clifton on Sept. 13th from South Africa.

The *Tamar* arrived at Southampton on Sept. 15th from South Africa with 64 invalids under the command of Major Alexander, R.A.M.C. The men were sent to Netley Hospital.

Lieutenant Nickerson, R.A.M.C., who was taken prisoner at Ventersburg on August 19th, has been released.

### SOUTH AFRICAN WAR CASUALTIES.

The total losses (exclusive of sick and wounded men now in hospital in South Africa) since the beginning of the war amount to 39,785. Of the 27,937 sent home as invalids 173 have died, 740 have been discharged from the service as permanently unfit, and 920 are in hospital. Among the missing and prisoners, however, are probably included a large number of officers and men who have been liberated or have subsequently rejoined.

### THE PREVENTION OF DISEASE IN THE FIELD..

We have called attention in another column to a letter from Dr. Leigh Canney recently published in the *Standard* on this subject, and have suggested that the matter should be taken up and considered by the War Office authorities, especially as Dr. Canney has been at the trouble to work out the calculations and details of a scheme showing how his proposals could be carried into effect. He deals mainly with the question in relation to the practicability of preventing such deplorable epidemics of typhoid fever and dysentery in armies as have recently occurred, for example, in South Africa, and he contends that the extent and prevalence of these diseases and probably of others of a kindred kind could be very materially diminished if not altogether prevented by the use of filtered or boiled water—giving preference for practical reasons to the latter method. He puts his calculations and estimates as follows:—

An army of 50,000 men such as moved from the Modder to Paardeberg, and thence to Bloemfontein, would require for—(*a*) Filtration: 500 filters (and each filter would require a fresh candle daily). Total weight, 50 lb. × 500 = about 11 tons. Total cubic space, 1000 feet. Or (*b*) boiling: 500 combined heaters and stoves in separate wooden cases. Total weight. 100 lb. × 500 = 22 tons about. Total cubic space, 3000 feet. This army would require as fuel about 150 gallons of petroleum and 20 gallons of methylated spirit daily. The boiling system would abolish the need for some 4000 kettles, probably supplied at present to this army and weighing, probably, about 20 tons. The boiling system would, therefore, only add two tons + the weight of 150 gallons of petroleum and 20 gallons of spirit to the 500 tons of stores daily necessary for such an army. The boiling system or the filtration system would render the transport of vast typhoid and dysentery hospitals unnecessary. As in war, as practised at present without prevention, there are five times as many cases of disease (mostly preventable) as there are of wounds, the hospital equipment to be transported, under preventive measures, could be reduced, if not by four-fifths, at least very largely.

### THE ROYAL ARMY MEDICAL CORPS ON SERVICE.

We may call our readers' attention to a communication published in the *Army and Navy Gazette* of Sept. 15th, from "A Staff Officer who does know." He bases his statements, which are strongly in vindication of the officers of the Royal Army Medical Corps, on the results of his own experience acquired in the field during the campaign in South Africa, and it is, we think, to be regretted that he did not append his name and rank to his letter which is a very good one and admirable in tone. Although we quite concur with him in thinking that it is essential for efficiency in war to have a strong corps of well-trained medical officers we are nevertheless of opinion that it will be also necessary to have in future a big reserve of civil surgeons. There is no reason why these civil surgeons should not receive some preliminary military training in time of peace, and then a comparatively short experience in the field would fit them for the discharge of their duties. There is room for the publication of a very useful manual of instruction as to the principles and methods of military and medical procedure in war.

### DEATHS IN THE SERVICES.

Fleet-Surgeon Thomas M. Sibbald, R.N., of the battleship *Centurion*, flagship of Vice-Admiral Sir E. H. Seymour, K.C.B., on the China station. The admiral and other officers and men of the *Centurion* had returned to their ship last month after their march back from Peking, and on the day following their return Fleet-Surgeon Sibbald, who was suffering from fever, was found dead in his bed. The deceased was very popular in the service. His body was sent to Wei-hai-wei by the steamer *Shen King* and buried with full naval honours by the ship's company of the cruiser *Powerful*. Fleet-Surgeon T. M. Sibbald was one of the officers of the Royal Navy who were recommended by Captain B. H. McCalla, U.S.A. Navy Department, for a medal for acting concurrently with other officers in the relief of Peking.

### THE RELIEF OF KUMASI.

An account of the relief of Kumasi published in the *Times* of Sept. 19th, and received through Reuter's Agency, gives a stirring picture of the sufferings of the besieged garrison. To add to these sufferings small-pox broke out in the fort. The cases had to be removed to a hut under the fort wall, and each day Dr. Hay, although extremely ill, clambered over the wall to visit these cases. In so doing he contracted fever for a second time. From the day of the escape of the Governor and his party until the fort was relieved a third of the garrison died from starvation.

"Audi alteram partem."

## "THE TREATMENT OF ACUTE ALCOHOLISM BY LARGE DOSES OF DIGITALIS."

*To the Editors of* THE LANCET.

SIRS,—In reference to your annotation in THE LANCET of Sept. 15th (p. 821) on the use of large doses of tincture of digitalis in the treatment of delirium tremens, I would like to mention that my father, the late John L. Paterson, M.D., of Bahia, Brazil, since 1877 treated all his cases, which were very numerous, with half-ounce doses of tincture of digitalis and never met with any evil result. He found that if the full dose were successfully administered the patient within half an hour fell into a deep sleep. In one case of very violent character the man, aged 37 years, slept for 16 hours straight off. He awoke with his head clear, but felt tired; this, however, soon passed off, for he got out of bed and went for a walk with his wife. The notes of the following case may prove interesting. A man, aged 50 years, much addicted to alcohol, was, after a heavy drinking bout, attacked with a very violent access of delirium. In the evening half an ounce of the tincture of digitalis was ordered; the medicine was fully administered and very shortly the patient vomited it. During the night he was so violent that, being a robust and powerful man, his friends were compelled to rope him down to the bed. On being visited at 9 o'clock in the morning it was discovered that the chemist had dispensed in error half an ounce of tincture of aconite. On being taxed with the mistake his only answer was, with a shrug of the shoulders, "Mistakes *will* occur." Having obtained half an ounce of the digitalis it was immediately given (9 A.M.). Within half an hour the patient was perfectly quiet, and gradually, hour by hour, became more and more himself and rational. His bonds, which had been so tightly tied that his wrists and ankles were swollen and cut, were loosed. He did not sleep, but lay with his eyes closed and complained piteously of the injuries to his hands and feet. At 10 P.M. he fell into a deep sleep and slept without intermission till the following morning, when he awoke with his head clear and free from any pain. His only trouble was the injury to his wrists and feet. There was no fever, but the pulse which before the digitalis had been full and normal in rate, became very small and fast (114). After a few days of weakness and loss of appetite he rapidly became well.

The smallness and rapidity of the pulse were noted in all cases treated with the digitalis. The case distinctly proves that, even when sleep does not occur immediately, the effect of the digitalis is to quiet the cerebral circulation. Another great advantage of the treatment is the fact that nearly all

the patients were able almost at once to return to their duties. I am, Sirs, yours faithfully,

Ascot, Sept. 17th, 1900. A. GORDON PATERSON, M.D. Edin.

## "PROFESSIONAL ORGANISATIONS."

*To the Editors of* THE LANCET.

SIRS,—Dr. Ryley is anxious to know why I agree as to the desirability of a central representative body in the medical profession. Partly in order that questions like those between him and the other Yarmouth practitioners might be settled by what both sides should recognise as the collective voice of the profession. Dr. Ryley also presses me to explain what is the attitude of the Yarmouth District Committee towards London consultants. Our resolution, quoted by Dr. Ryley, confines itself to medical practitioners in the town and neighbourhood, and the district committee has not gone beyond this. Having answered Dr. Ryley's questions may I ask one in turn?

So far Dr. Ryley has given no indication of his present views as to the conduct of the gentlemen with whom he desires us to consult. He will, I suppose, admit that these medical men accepted their present appointments knowing that there was a dispute pending between the united local profession on the one hand and a section of the public on the other, and that their acceptance was an act of hostility to the profession; that the advertisement of the appointments appeared only in the lay press, the medical press refusing unanimously to insert them; that the appointments themselves were at a fixed salary for attendance on an unduly large number of patients, all profit from their medical work going to the lay body; that the management was entirely in the hands of a lay committee; and that there was no restriction as to the class of patients to be attended. Considering Dr. Ryley's present attitude I think it not unreasonable to ask whether he esteems the action of these gentlemen deserving of professional reprobation, and if so how he thinks that reprobation should be expressed? I trust that Dr. Ryley's many professional and other engagements will not prevent his replying to this important question, especially as his answer need not be long.

As to "common humanity," Dr. Ryley's heroics are out of place. Common humanity is not at stake in the difference between himself and his Yarmouth fellow practitioners, and therefore he is not yet called upon to brave "ostracism or boycotting" in its defence. Our correspondence with him shows that the difference is not on the point of humanity, but on quite other issues. His demands were (*a*) that our attitude towards the institute surgeons should be referred to some "central representative authority," and (*b*) that that attitude should be modified in certain ways, which might, perhaps, be more agreeable to those surgeons but would make little practical difference to their patients. (*a*) fell through for lack of the mutually desired "central representative authority." The General Medical Council is restricted, as it has always held, by its statutory powers to taking cognisance of offences alleged to be "infamous in a professional respect," and Dr. Ryley's contrition for his former conduct has not yet led him to ask that such censure be passed upon it. The councils of the various medical corporations are only authoritative at most as to their own diplomates and are not strikingly representative of those. Of the British Medical Association Dr. Ryley is not a member, and, we believe, declines to recognise its ethical committee as either representative or authoritative. As to (*b*), we are, and have always been, prepared to give immediate help if called upon to the institute surgeons (or conversely, as Dr. Ryley points out, to accept it if necessary from them) in cases of sudden and grave emergency, or to treat their patients, gratuitously if necessary, who desire our advice. So much, we consider, is required by "common humanity," and suffices to meet its demands. Dr. Ryley desires us further to consult with the surgeon, but will not consent to waive the fee; thus the issue is not one of humanity to the *patient*, but of degree of recognition of the *surgeon* and of a possible small pecuniary sacrifice.

This, of course, is an *ex parte* statement whose fairness can be tested only by reference to the correspondence now in your hands. Should you, Sirs, afford space to publish that correspondence, your readers can judge for themselves; otherwise we leave it to you to say whether we have fairly stated the points involved. And if these be the points then we appeal with confidence to our medical brethren to say whether we or Dr. Ryley have shown a greater regard for "common humanity" and for the honour and interests of our profession. I am, Sirs, yours faithfully,

Great Yarmouth, Sept. 18th, 1900. W. E. WYLLYS.

*** We hope to publish an article dealing with this matter in our issue of next week.—ED. L.

## "ARE COPPER SALTS POISONOUS?"

*To the Editors of* THE LANCET.

SIRS,—Under the above heading there is an annotation in THE LANCET of Sept. 15th (p. 821) in which I am glad to find that the opinion I expressed in reference to the sale of so-called "greened" vegetables in a paper on the Action of Copper on the Human Body, read before the British Association (Chemical Section), has your support. When you say, "We do not object to the plan of preserving the colour of peas by copper" you expressly what I endeavoured to prove in a brief part of my paper. For though most of your criticism is directed to this point, it was a very minor one in my paper. Your objection to the purchaser not being notified that the purchased article is coppered I hardly thought came within the consideration of "the action of copper"—a question whose investigation was large enough to occupy me constantly since the beginning of this year. In my judgment, if so-called "greened" vegetables were poisonous or injurious notification as to their being coppered would not justify their sale—it should be prohibited. And with this, too, I have no doubt you are in agreement, because I anticipate you would not approve of the sale of poisonous or injurious food and also because you illustrate your objection by the case of meat cooked in a gas-oven being improperly represented as being roasted. When we are in agreement on the really important point it is undesirable to occupy your space by discussing minor points, where difference is mainly due to the necessary briefness of the abstract brought to your notice. But I would like to refer to an error in your remarks when you state that my paper was on the subject given in the above heading. Of course I never questioned that there are poisonous salts of copper. Some of them are referred to in the published abstract of my paper. The correct title of my paper I have given above, and but brief reference was made to the subject of coppered vegetables. My researches prove that salts of copper are being constantly absorbed into the blood and excreted by persons engaged in working copper ore and alloys of the metal, while they are unconscious of the fact and continue in perfect health, and that consequently they are not "poisoned"; further that copper salts ingested with food, or alone, lead to absorption into the blood and excretion of copper salts without the slightest ill effect.

I am, Sirs, yours faithfully,

Bradford, Sept. 15th, 1900. THOMAS WHITESIDE HIME.

## "PROFESSOR LUSTIG'S PLAGUE SERUM."

*To the Editors of* THE LANCET.

SIRS,—In discussing a scientific subject it is unnecessary to reply to the personal attacks made upon me by Dr. Mayr in THE LANCET of August 11th, p. 461. Such attacks in debate may be common on the continent of Europe, but Englishmen do not consider that they advance an argument. I need only remark that it seems an extraordinary thing that a correspondent cannot criticise reports and reputed results of a method of treatment without ignorance of the subject or wilful misleading being put forward to explain his opposition.

I have argued the value of the experiments referred to entirely upon their own merits and I still hold that even if alternate cases have been regularly taken with others as controls *it is not satisfactory evidence when moribund and other cases have been excluded.* In the later experiments we want to know how many and what proportion of moribund and convalescent cases were taken out from each series. The later results of this method of treatment may appear to the physicians concerned very satisfactory, but unless their system of experiment is above suspicion their conclusions cannot be convincing. My opponents and I are at issue upon the reading of the statistics

and upon the basis adopted for the construction of those statistics. Supplementary to what I have previously reported I should like to point out from the figures contained in Dr. Mayr's own letter that when "out-and-out" selection of cases was adopted the recovery-rate was 33·2 per cent., whereas when the patients were said *not* to be selected (although all the time moribund and convalescent cases were excluded) the recovery-rate was almost identical—33·8 per cent. Again, the controls are credited with only 21·3 per cent. recoveries, but this is the recovery-rate or thereabouts of all cases admitted to hospital without the exclusion of any cases whatever. If the excluded cases have been subsequently added to each series before working out the percentages the figures become intelligible, but this is not stated in any of the reports and we do not know whether the excluded cases were approximately equal in the two series. In a previous letter from Dr. Choksy he says: "The exclusion of moribunds and convalescents did not tell in favour of the serum," and the inference therefore is that these cases were not included. If that be so the whole series of figures are worthless, because if you deduct the moribunds from a given number of admissions the natural recovery-rate will be better than under the serum treatment. When moribunds or convalescents are excluded there must necessarily be the error of personal opinion as to the condition of the patient. If, therefore, Dr. Mayr or Dr. Choksy or Lieutenant-Colonel Wilkins can show a series of cases in which every admission has been included and in which the serum cases show better results than the others, or a series of cases in which the excluded moribund and other cases on the two sides are approximately equal, and still the results are satisfactory, I shall be glad to accept their conclusions.

At present I am not satisfied that the conditions thereby involved have been carried out and I am therefore not disposed to accept figures calculated on a faulty basis. With regard to Lieutenant-Colonel Wilkins's short letter I claim that it is not fair fighting to speak of "the inaccuracies which this (my) article contains" without stating what those reputed errors are. Lieutenant-Colonel Wilkins shelters himself under Dr. Mayr's letter, in which, however, there is not a single argument advanced against my reasoning but merely a statement of reputed results at the Arthur-road Hospital and various uncomplimentary remarks about myself. I am, Sirs, yours faithfully,

YOUR SPECIAL CORRESPONDENT.

## NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

*The Depletion of Field Hospitals in India and Arrangements for China.—The "Gwalior" Hospital Ship.—The Short-handedness of the Indian Medical Service.—The Cholera and Plague Epidemics.—The Increased Mortality in the Cities of Bombay and Calcutta.—Fresh Plague Regulations at Poona.*

THE Secretary of State has been informed that the medical arrangements made in India only provide for the requirements of the force sent from India and do not include the requirements of troops at China stations before the commencement of hostilities. As the supply of field hospitals sent to China is extremely liberal and as the greater part of the troops have gone from India the hospital accommodation will probably meet all requirements. In the meantime, however, the reserves of hospital equipment in India have been depleted and the India Office has therefore been asked to despatch immediately to India complete equipment for the four general hospitals of 500 beds each required for the China force. All the hospitals have been fully equipped with comforts, surgical appliances, and mosquito nets. Thirty dandies with 180 bearers to each field hospital have been despatched. Water transport is largely relied on, but nine tongas have gone and more will follow when the roads are reported fit. One field medical store has been sent to the north and another to the south of China. The following arrangements have been made. For Europeans, strength about 1000: for officers, 10 beds; for men, 200 beds. In field and general hospitals also 175 beds. In the hospital ship *Maine*, for natives, strength about 30,000 combatants and non-combatants, 1300 beds; in native hospital ships containing about 365 beds, and for reception at Calcutta General Hospital, 500 beds. The *personnel* sent or going to China are 135 medical officers, 25 assistant surgeons, and 224 hospital assistants; five nurses are attached to the general hospital.

The Maharajah of Gwalior's hospital ship *Gwalior* is a fine vessel of 4200 tons register. Her main deck will provide accommodation for 160 beds. In the orlop deck will be the hospital with accommodation for dressers and ward orderlies. There will be six special swinging beds for fracture cases. Convalescents will be accommodated on the saloon deck. There are three medical officers' cabins which are supplied with electric bells so that they can be communicated with at any time both day and night. A disinfecting-room, mortuary, and latrines for the staff are provided on the upper deck forward. A special machine for disinfecting clothes similar to the one used on the *Carthage* will arrive shortly. On the poop will be a completely isolated infectious ward with 16 beds. Roentgen ray apparatus will be taken. There is a complete service for drinking-water for all castes. Lieutenant-Colonel A. M. Crofts, I.M.S., will be in principal medical charge with Captain M. Moore, I.M.S., and another officer. It is stated that His Highness the Maharajah is prepared to spend £100,000 upon this undertaking.

In view of the drain upon the medical service the Government of India have issued orders recalling Indian Medical Service officers on leave on private affairs, and the Secretary of State has been asked to inquire whether retired medical officers will volunteer for service in India. The Government have also sanctioned a proposal for the re-engagement of pensioned military assistant surgeons on the same pay as they used to draw before. Major J. T. W. Leslie, I.M.S., Major F. P. Maynard, I.M.S., and Captain G. Smith, who are now engaged on special scientific work at home, will return to India.

A further considerable increase in the plague mortality throughout India is reported, the total number of deaths in the past week having risen to 629 from 449 for the previous week. The chief rise is in Mysore State (281), Mysore city returning 188 and Bangalore city 21. In Bombay city the mortality increased from 51 to 75, and in the province from 64 to 160. In Calcutta there were 84 deaths and in the Bengal districts 18. The remainder of India continues free.

While cholera continues to be very prevalent in Bombay city and a few other places it is satisfactory to find that among the troops it is decreasing. The total numbers since August 3rd are 271 cases with 165 deaths. There have been over 400 deaths from cholera during the past week in Bombay city and over 100 are reported in Kashmir. In Calcutta there were only nine.

The general mortality in Bombay city has decreased from 2203 last week (rate 136·87 per 1000) to 1624 this week. Of this number 64 are returned as due to plague and 408 as due to cholera. These figures still leave about 400 deaths to be accounted for. The sudden rise was doubtless due to cholera and the deaths occurred in all parts of the city. There is said to be at the present time a large ill-fed mendicant population in consequence of the closing of several mills and of the famine. The infantile mortality amongst the poorest classes is also described as terrible, and it is said that on one day 60 infants died. The returns show a sudden increase of deaths from phthisis. Usually about from 80 to 90 deaths a week, they rose to 161 and then to 210. With respiratory diseases the figures under this head trebled the average and in a single week 500 deaths were recorded from this class of disease alone, the normal general mortality of Bombay being from 500 to 600 deaths a week.

The general mortality in Calcutta is also higher than usual. With an average of about 30 per 1000 it has increased from 37·2 per 1000 for the week ending August 4th to a rate of 42·2 per 1000 this week, and seems likely to go higher still. There is an increase of nearly 50 per cent. over the normal. Part of this is explained by extra deaths from cholera and small-pox and from plague and suspected cases. There is a residuum of about 200 deaths during the past week unaccounted for.

Fresh plague regulations of a very modified form have been recently promulgated at Poona. They are apparently the result of the recent resolution of the Government of India on the report of the Plague Commission. Many of the old orders have been omitted. There will be disinfection of houses in which plague has been found to exist and also of adjoining houses. Free inoculation will be available at convenient hours and facilities will be given for inoculation at

home. This is about all. The minimum of interference has at length been arrived at in Poona, but this minimum has long been attained in Calcutta. There is no evidence to show that the avoidance of active measures in Calcutta contributed to the outbreaks. On the contrary Calcutta has suffered much less than other places have suffered.

August 30th.

# THE FIRST INTERNATIONAL CONGRESS OF THE MANUFACTURERS OF PHARMACEUTICAL SPECIALITIES.

(FROM OUR SPECIAL CORRESPONDENT.)

## RAPID GROWTH OF THE TRADE IN "MEDICAL SPECIALITIES."

THE rapid development of the trade in pharmaceutical specialities has occasioned much recrimination and many ardent controversies. The special drug, the secret remedy, the nostrum were strongly denounced at the International Congress of Deontology or Medical Ethics. In spite of the hostility of the medical profession and the dispensing chemists the pharmaceutical speciality has become an important and separate branch of trade and has been increasing by leaps and bounds. So great is this progress that the manufacturers of these specialities have been able to hold an international congress which met at the Palace of Congresses on Sept. 2nd and 3rd and had no less than 468 members. Though 371 out of these were French manufacturers and druggists there were a great many foreign nations represented, but they sent only few delegates. As is often the case, the smallest countries had the greatest number of representatives. Thus while Great Britain had only four, Germany five, Austria three, the United States two, and Russia one, Belgium had 10, Italy 11, Cuba eight, Bolivia four, Brazil three, Egypt four, Holland three, Mexico four, Switzerland four, Bulgaria, Algeria, Spain, Hayti, and Peru two each, and Chili, Colombia, Greece, Guatemala, Sweden, Tunis, Portugal, Turkey, and Uruguay one each. But what are more remarkable than these figures are the statistics given of the exhibitors of pharmaceutical specialities. At the Universal Exhibition of 1855 there were only five such exhibitors. In 1867 their number had increased to 23, and in 1878 to 29, and they were all French. It was said in the course of the debate that this branch of the trade existed 50 years ago, but that it did not really develop and become important till within the last 25 years. Thus it is that at the Universal Exhibition of 1889 we find that there were no less than 154 exhibitors of pharmaceutical specialities, and these were no longer only French firms but 87 of them came from other countries. At the present Universal Exhibition there are 399 exhibitors of pharmaceutical specialities, and of these 138 are foreign and colonial. These figures are sufficiently eloquent. In the face of such facts the necessity of regulating this trade in a satisfactory manner is recognised by practical men. It was to attain this end that the Congress in question was convoked.

An influential organising committee had been formed. Its president, who also presided over the Congress, was M. Victor Fumouze, M.D., Pharmacist of the First Class, Honorary President of the Union of Manufacturers for the Protection of Industrial Property, and member of the firm of Fumouze Brothers. It was Dr. Fumouze who on behalf of the French Chambers of Commerce received and entertained the delegates of the British Chamber of Commerce when they assembled last week in Paris. The secretary of the committee was M. M. Leprince, M.D., Pharmacist of the First Class, Laureate of the Faculty of Medicine, of the upper School of Pharmacy and of the Hospitals of Paris, Member of the Committee for Class 54, Group IX. of the Exhibition. The other members of the committee also held highly honourable positions. The majority of the manufacturers who were members of the Congress deal exclusively with the medical profession, advertise only in the medical journals, and do not appeal to the general public. Still some of the members of the Congress belonged to the other class which does advertise in the lay press and caters for the general public.

M. A. GIRARD read the first report submitted to the Congress which dealt with the general conditions of the trade. He remarked that English specialities were exported because Englishmen when abroad required these medicaments, but that French and German specialities were sent abroad because of the high reputation which they enjoyed. Practically France, Germany, and England were the only countries that did a large export trade. It was difficult to ascertain the amount of these exports as the drugs were not entered by the customs under the heading of "specialities." Still, it was easy to see that the largest purchasers of French remedies were the States of Southern America. In Europe the largest quantities of French pharmaceutical specialities were sold in England, Belgium, and Spain. The French imported more from England than from all the other countries put together. The report then reviewed the trade of a great number of countries and when it had been read a short discussion ensued which concluded with the adoption of the following motion:—

That in each country administrative or legal restrictions brought to bear on the importation and sale of pharmaceutical specialities should have no other object than that of protecting public health. That the common law should apply to these products in regard to legal, administrative, or fiscal restrictions, press censorship, stamp duties, special taxation, &c.

## ABOLITION OF SECRET REMEDIES.

At the second or afternoon sitting M. AUGENDRE read a lengthy report on the law in different countries with regard to secret remedies, &c. That of England was summed up as "perfect freedom for those who possessed a diploma." But while there were regulations with regard to poisons there was no direct interference with pharmaceutical specialities, and yet trade-marks were protected throughout the United Kingdom. The most interesting passage of the report, however, related to Belgium, because it analysed a new project of law which was not only likely to be adopted in that country, but is very similar to the project which M. Astier had introduced in the French Legislature. Article 25 of this project of law stipulates that all drugs must be of good quality and Article 27 that druggists will be held responsible not only for what they have sold but for what they keep in stock for sale. Article 28 introduces a most important and novel stipulation. It enacts that medicaments prepared for private persons at the request of the purchaser or in virtue of a medical prescription shall bear a label mentioning in very clearly written characters its qualitative composition or the passage from the Pharmacopœia or the formula which has been employed. If such medicaments contain a toxic substance the quantity used must likewise be clearly indicated on the label, in the pamphlets, and in the prospectuses relating to the same. The Government is to prepare a list of toxic substances to which the latter clause shall apply. The dispensing chemist whether he sells a manufactured speciality or not is alone held responsible. If such speciality contains a toxic substance the druggist may only sell it when the purchaser presents a medical prescription. In France the pharmacists are governed by the law of the 21st Germinal Year XI., and by no less than 32 different ordinances, decrees, &c., issued since that date. But on June 12th last M. Astier introduced in the Chamber of Deputies a Bill which, as already observed, is very similar to the Belgian project of law. In the preamble to his Bill M. Astier says that above all the dispensing chemist must remain a man of science on whose probity and devotion the public can rely. But he goes on to explain that the science of chemistry as applied to therapeutics has made gigantic progress. Formerly only a few substances were employed, and these could all be manipulated in the druggist's shop. Now many of them have to be made wholesale in large factories, whence they are purchased by the dispensing chemist. The entire position has changed and the law must also be altered. Consequently M. Augendre concluded his lengthy report by proposing resolutions to the effect that every effort should be made to assimilate the regulations governing the importation of pharmaceutical specialities into different countries, that the trade-mark of the manufacturers should be protected from imitations, and that the custom duties imposed should not exceed 10 per cent. of the value of the article. These suggestions were adopted after some discussion. The general tone of the debate showed that the members of the Congress were mostly in favour of reciprocity and were anxious to see pharmaceutical specialities figure as distinct objects of exportation and importation in all future treaties of commerce.

## THE INVENTOR AND HIS MARK.

The second day of the Congress was mainly devoted to the

reading and discussion of M. LÉON COMAR'S report on the protection of trade-marks. This paper was a masterly summary of this somewhat intricate question, in which many interests conflict. As a manufacturer the druggist incurs the same risks, pays the same taxes as other manufacturers, and therefore should have the right to select a trade-mark. But, unlike other manufacturers, he must pass examinations, possess diplomas, and is subjected to special interferences of the law. In France there is, further, a tendency to deny his right to a trade-mark on the ground that this may deprive the public of a useful remedy, and therefore the druggist is not to enjoy any advantage from a discovery or invention which he may make. Most countries, however, do recognise that the manufacturer has the right to preserve the distinctive name by which his particular product may be recognised. But the giving of such a name is a matter of great difficulty. The name of the principal ingredient cannot be used because it is a word that is the common property of all. On the other hand medical men very naturally insist that the name shall indicate what is the principal ingredient, and it is difficult to reconcile these two exigencies. It is consequently necessary to invent a word that is not the real word and yet that shall indirectly indicate the nature of the substance. M. Comar brought forward a series of propositions demanding that trade-marks or manufacturers' marks should be recognised and protected in all countries, that the name of the manufacturer might be considered as a trade mark, that such trade-mark might include the indispensable descriptive word, such as "syrup," "powder," "pill," &c., and that all nations should adopt similar patent laws. Most countries allow processes of manufacture to be patented, but will not give patents for chemical, pharmaceutical, or alimentary products. Great Britain, Belgium, Brazil, Mexico, and Guatemala alone protect both the process and the product.

### APPROBATION FROM THE ITALIAN GOVERNMENT.

M. PELLETIER, who was delegated by the French Government to help in the negotiation of various treaties of commerce, complimented M. Comar on his lucid exposition of the situation. Every other form of human art and industry had subdivided itself into specialities and druggists were bound to follow this law. By devoting themselves to one particular branch they would produce better drugs, and this was to the benefit of the sick and to that of the medical practitioners who would be better able to rely on the effect of their prescriptions. The manufacturer on his side was entitled to a legitimate profit when he effected a real improvement. But such protection was denied to the manufacturers in France by the decree of 1844 on the ground that nothing must be done to encourage charlatanism. To patent a drug would seem like endorsing a charlatan with Government approbation. But since then economic conditions had greatly changed. Industry was the transformation of raw materials into something that could be sold to the public. This was what the druggist did, and he paid taxes and might become bankrupt like other manufacturers. Even a patent might be granted, for it placed the secret into the public domain and generally stimulated industry and progress. The patentee's financial advantage did not last long. But it was said that by granting a patent a marvellous remedy might be kept back and delay occur before it became accessible at a cheap rate. To meet such comparatively rare cases the State might retain the right to purchase patents for the public good.

M. MAILLORD DE MARAFY regretted the present dispute between the dispensing pharmacists and the manufacturing pharmacists. Their trade interests might be antagonistic, but not so their general human interests. Resolutions of a congress only influenced governments in so far as they were supported by good arguments. In all branches of trade the same product bore the same name. Why should not the chemist, who had to incur an expensive education, enjoy the same privilege as the grocer or biscuit-maker? Yet in France a law to this effect had been under discussion for 20 years and had not yet been passed. He then quoted an extract from a Ministerial circular from the Italian Government dated March 8th, 1884, which stated that: "No one contests the advantages which pharmaceutical specialties may realise. There is the purity of the substances employed, their rational treatment so as to ensure the therapeutic action of the principal ingredient to modify, if need be, some secondary effect which may be unfavourable from the curative point of view. Then there is the care taken so that the preparation shall be perfect and as far as possible not liable to deterioration, and also to avoid chemical incompatibilities that might render useless the action of the medicament. Also these preparations sometimes succeed in conferring to the remedy a flavour and appearance that are pleasing to the patients." M. de Marafy remarked that it was often said that testimonials in favour of specialities were only obtained by bribery, but he thought that this testimonial given by the Italian Government could scarcely be attributed to any such corrupt origin.

The PRESIDENT (Dr. Fumouze) remarked that the dispensing chemists at their congress had carried a motion to the effect that no commercial scientific denomination should be allowed to constitute a trade-mark. He agreed that the manufacturers of special remedies should inscribe on their labels the dose of the active principle employed, but they ought not to be compelled to describe all the component parts of the preparation. To give the complete prescription would enable anyone to produce identically the same remedy. This and the denial of the trade-mark would destroy the business of the pharmaceutical specialists. Also whatever the details to be given on the labels the rule should be the same for all countries, otherwise inextricable confusion would arise. They were ready to give all information necessary for medical purposes but not such details as would render imitation easy.

### THE GENUINE AND THE QUACK REMEDY.

M. ASTIER explained his action in Parliament. Though himself a specialist he had altered Article 5 of the Bill so as to safeguard the interests of the public. One was rarely gifted with all reason and no error. It must be recognised that pharmacists were a privileged class. The industry of manufacturing and dispensing drugs was monopolised by those who held the diploma. Such monopoly was against the principle of freedom to trade conferred by the great Revolution; therefore the nation had in exchange for the privilege granted the right to impose special burdens and responsibilities. There was a weak side in the claims of the specialists. When a specialist proposed to make hair grow and corns drop off with one and the same substance it was not surprising if the public felt some doubts in granting all the demands of the specialists. When he proposed in the Bill that the dose of the active principles should be stated he wanted to check the vulgar parasites who imitated genuine and useful remedies which had been produced after much study and expense. He had no care for the mountebank hangers-on to what should be a highly scientific and respectable trade. He also appreciated the objections of the medical profession. If, for instance, a medical practitioner on being called in found the patient in a condition of collapse and was told that he had been taking some patent syrup, how was it possible to give an antidote or to alter suitably the treatment unless there were means of knowing, and that immediately, what the syrup in question contained? This should be inscribed on the label.

M. BERNEVILLE, a Belgian delegate, agreed that the active principle of the medicament should be stated on the label. It should be known what was being taken and in what doses.

This principle as defined by the Bill before the Belgium Parliament was formulated as a resolution and adopted by the Congress. The matter, therefore, stands thus. The Congress repudiates the idea of secret remedies; some detail in the mode of manufacture or of putting together the preparation might be kept from the public but the active principle must be disclosed. No one must prescribe or take medicine in ignorance of its active potentialities. Knowing this much any dispensing chemist might be asked to prepare something similar. If he did this and the result was as good, and especially if the medicament were cheaper, then the speciality would die a natural death; in fact, it would have been demonstrated that it did not deserve to be called a speciality. On the other hand, if it was something that the ordinary chemist could not readily imitate then it deserved to stand because of its special or exceptional merits. This principle if acted upon would certainly be the death-knell of many so-called specialities, but it would purify an important and ever-increasing trade, would silence the accusation now so freely made of charlatanism or quackery, and would be an encouragment to genuine inventions, discoveries, or improvements. Such was the upshot of this somewhat remarkable Congress and of the first international meeting of pharmaceutical specialists ever held.

Paris, Sept. 10th.

# THE PRESIDENCY GENERAL HOSPITAL, CALCUTTA.

NEW BLOCK FOR MEN.

(FROM A CORRESPONDENT.)

THIS new hospital, about which I propose now to give only a preliminary notice, is not yet open for the reception of patients. The building consists of a central block which will be chiefly taken up by administrative offices and private wards with a large rectangular block on each side. These contain the six main wards, two on each floor, and will accommodate 24 patients in each ward. There are at the inner end of the ward the ward offices and at the outer end of the building are the lavatories. The building has three storeys and is superimposed on what is practically a series of pillars, giving a free air space eight feet in height below the ground floor. The aspect is north and south—the building running east and west—because the prevailing winds are from the south. A wide verandah runs round each floor from one end of each block to the other. The roof is flat and affords a most excellent promenade extending over the whole building. The main wards are 108 feet long by 26 feet wide and are 16 feet six inches from floor to ceiling. As they are arranged to accommodate 24 beds this gives 116 superficial square feet for each patient and 1914 cubic feet capacity. There is a doorway between each bed so that the circulation of air can be almost as free as out of doors. The floor is cemented and the wall is tiled five feet up. There are no ledges for dust to collect on. The ward closets and lavatories are isolated from the main block and occupy the small wings at the east and west extremities of the building. The medical attendant's room and the nurse's room are arranged to overlook each ward. Besides the verandah there is a day room for the patients of each ward. There are also two separation wards to each main ward, which are placed in the block containing the ward officer. The central block contains six private wards on each storey. The operating room is beautifully situated over the porch. It faces north and is open on three sides. There is an anæsthetic room leading into it, also a splint and bandage room close by.

The design of the building is excellent and is so arranged as to adopt all the latest improvements. The architecture is plain, but the building taken as a whole is imposing. There have yet to be built nurses' quarters and kitchen quarters as well as quarters for infectious cases. These will all be isolated from the main building and also from each other. The lighting will, of course, be by electricity, which will also be the motive power for the punkahs. At some future time it is proposed to build a similar structure for women, this one being intended at present solely for men. When the hospital is furnished and ready for occupation I hope to send you a second notice referring to details, as I have here merely attempted to describe its main features.

# BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

*The Musical Festival.*

THE Birmingham musical festival is a triennial occurrence which will fall this year in October. Much interest is attached to the performances since the proceeds form an important element in the funds of the General Hospital. Formerly the festival was held in August; on the last two occasions it was changed to October without any diminution in the receipts. On the present occasion the programme which has been issued gives evidence of a very full and complete list of works, and bids fair to uphold the reputation which the festival has always enjoyed. The first musical festival in aid of the hospital was held in 1768, when a sum of £299 was realised; for the last festival, in 1897, £5117 was the amount of the net return. In addition to this the valuable organ in the town hall, valued at upwards of £5000, is the property of the General Hospital, as is also an extensive musical library. It would be needless to mention the musical works to which the festival owes its celebrity. The *Elijah* was first written for this festival, and its performance was conducted by Mendelssohn himself in 1846. Since then other works destined to produce a lasting fame for their authors have been brought out here. Copies of the programmes for the present year with all arrangements can be obtained from the committee at the town hall.

*The "Long Pull" Question.*

The general opinion is that the "long pull" in the beer trade is a pernicious habit, that it leads to unfair competition, and that it tends to the increase of drunkenness. The question is complicated much by the attitude of the wholesale trade and the fact of what are called free licences. It would appear from the variety of conflicting points introduced at the licensing sessions that some attempts have been made to influence the decisions of the Bench. To outsiders who hear that the "long pull" is, or should be, limited to 25 per cent. over-measure, some impression must be conveyed of the profits which admit of this liberal measure and yet leave sufficient to cover all the expenses of which the trade complains.

*Plague Precautions.*

That the authorities are actuated by a desire to prevent as well as to cure is evidenced by the fact that the medical officer of health of the city has been notified by the medical officer of health of Glasgow of a Birmingham gentleman who travelled from Glasgow to Greenwich in the steamship *Copeland* and then proceeded home to this city. He will be kept under strict but unobtrusive notice so as to ensure every precaution should he be the means of spreading the disease.

Sept. 18th.

# MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

*Out-door Relief.*

IT may, no doubt, be taken as a sign of the increasingly humanitarian feeling of the times that boards of guardians are less rigid than they used to be as to granting out-door relief as an alternative to the offer of "the house," and if the practice is sufficiently safeguarded with respect to abuse there seems to be no good reason against an extension of it. At all events this seems to be the feeling at the Salford board, for at the meeting held on Sept. 14th the attention was drawn to the question by one of the guardians asking for an explanation of the increase in out-door relief, "especially in view of the present state of trade and the favourable weather." The explanation was that "the general disposition nowadays both by boards of guardians and the public was in favour of giving a little more out-relief." Three years ago the amount distributed per week was £115 and it has increased to £140.

*The Cancer Pavilion and Home.*

Mr. F. A. Southam and Mr. G. A. Wright have accepted appointments as honorary surgeons to the Manchester Cancer Pavilion and Home.

*Registration Difficulties in Fallowfield.*

Some inconvenience is felt at Fallowfield, a rapidly increasing suburb of Manchester, as to the registration of births and deaths. A new and populous district is attached most inconveniently to Ardwick which is not easily accessible, while the attendance at the branch office in Rusholme is very meagre. The matter was brought to the notice of the Chorlton board of guardians on Sept. 14th by a letter from Dr. W. E. Sawers Scott suggesting that "the increase of population warranted a readjustment and increase of the number of districts." The clerk said he would "ascertain from the registrar whether more attendance could not be given at the Rusholme branch office." All reasonable facilities should certainly be afforded for registration.

*Preservatives in Milk.*

A milk-seller was charged the other week before the Bolton county justices by the Lancashire County Council with selling adulterated milk. Mr. Wilson of Preston, who appeared for the council, said that they desired to give the utmost publicity to the case, "which had been brought to put a stop to the growing practice in Lancashire of putting preservatives in milk." It seems that the sale of such things is being actively pushed among the farmers by agents selling formalin and other preparations. Part of a pint of new milk bought by the police was sent for analysis and found to contain formalin, the amount of which could not,

however, be ascertained by the methods at present in use. Dr. Collingwood Williams, one of the county analysts, spoke to analysing and detecting formalin, which was a powerful preservative, which was very pungent and irritating, and which made the milk less digestible. Mr. E. Sargeant, medical officer of health for the county, objected to the use of any preservative in milk. He thought formalin specially dangerous, particularly in the hands of inexperienced people. "It retarded digestion and was specially injurious to young people." The defendant said that a man from Rochdale called on him and sold him a small bottle of the preservative which was called "lacticine," for which he paid 2*s*. 9*d*. He used 10 drops of it, less than the quantity directed, to 40 quarts of milk. There was a thunderstorm at the time and he was afraid that the milk would not keep through the night. He gave up the bottle to the police. The presiding magistrate said that as the defendant "had helped them all he could" he would only be fined 10*s*. and costs. There is no wonder that farmers should wish to save so readily decomposing a substance as milk from being spoiled and it would be well if county council agricultural lecturers would give instructions as to the best ways of dealing with it from the moment it is received into the milking-pail until its delivery to the consumer, not forgetting to inculcate the cleanliness of hands and udder so often considered unnecessary by the rustic mind.

*Ice-cream Manufacture.*

The manufacture of ice-cream for sale in the streets is a matter engaging the attention of the corporations both of Manchester and Salford. It is chiefly in the hands of poor Italians who are careless and ignorant as to points of hygiene and generally too poverty-stricken to be able to conduct their work on suitable premises. At the Manchester city police-court Carolina Fuska was summoned by the Sanitary Committee of the corporation and fined 5*s*. and costs "for storing ice-cream on her premises without taking proper precautions for protecting it from infection or contamination." Victor Crolla was also fined 5*s*. and costs "for manufacturing ice-cream in a place which was in a dirty condition." These were the first prosecutions of the kind in the city, and the presiding magistrate said that in future more severe penalties might be imposed. At the meeting of the Salford council the other week it was said that the question as to the regulation of ice-cream vendors would come up at the next meeting of the Watch Committee. One of the members stated that it was not possible to license the ice-cream vendors. They had tried to get powers in their Act of 1899, but the matter was struck out of their Bill.

Sept. 18th.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

*Workmen's Dwellings and the Demolition of Insanitary Property.*

THE re-housing of the poor who have been dispossessed of their tenements owing to the demolition of insanitary property continues to be a source of anxiety to the Insanitary Property Committee of the City Council. An outcry has been raised against the hardship inflicted upon tenants through their being dispossessed of their holdings without means being taken to provide them with more suitable dwellings. The matter is now engaging the attention of the committee insomuch that the city surveyor has been instructed to report how far tenants of municipal dwellings lived from their work. There can be no doubt that the introduction of electric tramways throughout the city minimises the hardship imposed upon workmen in having to reside at a distance from their occupations, as the city is quickly approached from any point at a cheap rate. A special meeting of the City Council was held at the town hall on Sept. 13th to consider a recommendation of the Insanitary Property Committee—

That powers be obtained by provisional order or Act of Parliament to borrow a sum of £200,000 to enable the council to purchase and demolish insanitary houses under the provisions of the Liverpool Sanitary Amendment Act, 1864.

The recommendation was carried by a substantial majority, an amendment reducing the amount to £50,000 having been previously defeated.

*Civic Grant to the Hospital Pavilion at Fazakerley.*

The City Council at their meeting on Sept. 13th resolved that £4000 should be placed at the disposal of the Port Sanitary and Hospital Committee for furnishing the hospital pavilion on the Warbreck House estate at Fazakerley.

*The Inter-parochial Hospital for Tuberculosis.*

The final stage in the matter of the proposed inter-parochial hospital for the treatment of tuberculosis has now been reached. The joint parochial committee of the three unions —Liverpool, West Derby, and Toxteth Park—have given instructions to the architect to proceed with the erection of the hospital at Heswell on the site alluded to in THE LANCET of July 21st (p. 223), at a cost not exceeding £5700.

*The Roentgen Rays at the Liverpool Workhouse.*

The introduction into the workhouse hospital of the apparatus for applying the Roentgen rays affords proof of the intelligent interest taken by the Select Vestry in the treatment of the sick poor of the parish of Liverpool. The hospital contains a fine operating theatre and a post-mortem room fully equipped. Dr. W. Alexander is to be congratulated upon the numerous improvements initiated by him in recent years and upon having made the most of a building which by comparison with other general hospitals throughout the city was fast becoming out of date.

*The Plague in Foreign Ports.*

The Town Clerk of Liverpool has sent out notices that the Health Committee have decided to put in force the provisions of the Infectious Diseases Notification Act for one month from the date of the notice in the case of bubonic plague, should it unfortunately gain access to the port of Liverpool. The Select Vestry are also taking precautions against the plague in the establishment of an isolation ward in the Liverpool Workhouse.

*The Outbreak of Anthrax in Cheshire.*

A further outbreak of anthrax has occurred in another farm a short distance from that recently affected at Cuddington, near Northwich. Two more cattle have died, and the farm has been declared an infected area by the veterinary inspector to the Cheshire County Council.

*University College: Election of a Professor of Physics.*

Mr. L. R. Wilberforce, M.A., of Trinity College, Cambridge, has been elected to the Chair of Physics vacated by the appointment of Dr. Oliver Lodge to the principalship of Birmingham University. Mr. Wilberforce succeeded Mr. Glazebrook, the late principal of University College, as demonstrator in physics at the Cavendish Laboratory, Cambridge, and was recently appointed University lecturer in physics. He is now the secretary of the Special Board of Studies for Physics and Chemistry at Cambridge. Mr. Wilberforce has the reputation of being a most successful teacher.

*Donation to the Bootle Borough Hospital.*

The treasurer of the Bootle Borough Hospital has received £1000 from the executors of the late Mr. John Harling, of Manchester and Southport.

*The Royal Alexandra Children's Hospital, Rhyl: Opening Ceremony.*

The fine pile of buildings on the marine drive, Rhyl, known as the Royal Alexandra Children's Convalescent Hospital, was formally opened on Sept. 14th by the Countess of Dundonald. The foundation-stone of the new building was laid by Her Royal Highness the Princess of Wales on the site of the old hospital, then situated on the promenade; but in response to the wishes of the town council it was decided to remove the hospital to a new site further east. The new site has an uninterrupted sea frontage of 265 feet, comprising two acres of ground. When complete the building will contain 160 beds as well as accommodation for 25 nurses, many of whom will be engaged in work outside the hospital. The late Duke of Westminster contributed £10,000 towards the cost of the building. Messrs. Waterhouse and Son of London are the architects.

Sept. 18th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

*Public Health in Dublin.*

A SPECIAL meeting of the corporation of Dublin was held at the City Hall on Sept. 14th in order to declare bubonic

plague a notifiable disease for a period of 12 months. Mr. Bergin, chairman of the Public Health Committee, proposed a motion to that effect which was passed. A long discussion was held as to the best place in which such cases might be isolated for treatment. At its conclusion it was ascertained that the Convalescent Home in connexion with Cork-street Fever Hospital, Benevan, was really more suitable for many reasons than the accommodation at the Pigeon House Fort, for the 24 beds now available at Benevan could easily, if necessary, be increased to 100, while the alterations now being made at the Pigeon House Fort rendered such an extension there impossible for many months. A resolution to the effect that any patients suffering from bubonic plague in Dublin should at once be sent to Benevan was passed. Referring to the objection raised by some of the residents in that neighbourhood the chairman of the Public Health Committee called attention to the fact that Benevan had been for years used as an isolation hospital for diseases of a much more infectious nature than bubonic plague. Quoting from a recent memorandum of the Royal College of Physicians of Ireland he said: "It is reassuring to know that the plague although 'catching' is not nearly so infectious as scarlatina, typhus, small-pox, or measles. Attendants on the sick in clean, roomy, airy hospital wards run little risk." He added that in view of that statement there need be no apprehension on the part of the people at Benevan.—Dr. John J. Cranny addressed a letter to the *Irish Times* of Sept. 17th calling attention to the frequency of wakes in Dublin and to the fact that the epidemic of plague in Glasgow has been traced to this cause. He suggests as a practical remedy that mortuary chapels where the bodies of the dead could be placed during the interval between death and burial should be attached to the churches in every parish and be under the care of the different ministers of religion.

*The Irish Hospital at Pretoria.*

Lord Iveagh received a telegram on Sept. 17th from Sir William Thomson which was dated Sept. 15th and stated that all were well.

*Royal Army Medical Corps.*

The Secretary of State for War has recently placed nominations to commissions in the Royal Army Medical Corps at the disposal of the Royal College of Surgeons in Ireland and the Medical School of the Catholic University.

*Meat Inspection.*

At a meeting of the Market Committee of the Belfast County Council, held on Sept. 15th, a very valuable report was submitted by Dr. Henry O'Neill, J.P., who is a member of the Belfast Council and was appointed by that body to represent them at the Conference on the Housing of the Working Classes held in connexion with the Sanitary Institute in London in July last and at the Congress of Hygiene and Demography held in Paris in August. He was requested to obtain information concerning the housing of the working classes, the inspection of meat-supply, and the inspection of the milk-supply of cities and towns and its municipal control. Dr. O'Neill, besides attending the Congress of Hygiene and Demography, visited the principal abattoirs and meat markets in Paris, Berlin, London, and Manchester. As might be expected, Dr. O'Neill's report brings out how thoroughly this question of meat inspection is managed in Berlin. All cattle offered for sale in that city must be brought to the public abattoir and the slaughtering of cattle anywhere else within the municipal boundary is absolutely forbidden. All dead meat slaughtered in the country or abroad and intended for human food in Berlin must be brought to the public abattoir and meat market for inspection before being offered for sale as human food, and no butcher in Berlin can offer meat for human food which does not bear the official stamp of the inspecting department of the central market. As a result of this thorough method of inspection as conducted under the control of the municipal corporation of the city of Berlin a person may purchase meat from any butcher's shop in the city and feel certain the meat has been carefully inspected, stamped, and officially declared fit for human food. As showing how effectively this inspection is made in Berlin it is enough to say that the chief inspector of meat is a thoroughly qualified veterinary surgeon who has under his control a large staff of surgeons, assistant surgeons, special inspectors, and stampers. In Paris there are three public abattoirs and no private ones are permitted, and the flesh of the animals, after being killed, is carefully examined by qualified meat inspectors under the superintendence of a veterinary surgeon and if the meat is healthy and good for human consumption each quarter is stamped (a sign to the buyer that it has been examined and passed). Flesh of animals killed outside Paris is called foreign meat, and when brought into the city must be introduced through one of the city toll gates, and the person introducing it has to conform to a series of regulations which are rigidly enforced, one of these being that the meat must be inspected at certain establishments named. If found sound it is also stamped. The great feature of the Berlin method of the inspection of meat is—apart from its thoroughness so characteristic of German organisation—the fact that the city corporation has erected a combined cattle market and public abattoir for the entire city and so there is admirable centralisation. In London the inspection of meat is incomplete, but an improved method is at present under consideration so that all meat brought into London for use by the citizens as human food shall be properly inspected and stamped. Mr. Shirley Murphy has reported to the London County Council fully on the matter and Dr. O'Neill quotes freely from him. In Manchester there is, as in London, not a complete inspection of all meat brought into the city for human food, and the meat which is inspected is not stamped. Dr. O'Neill recommends the Market Committee of Belfast to adopt a system of meat inspection somewhat similar to that of Paris and Berlin, but wisely suggests that before coming to a final decision a small sub-committee of, say, two should visit London, Paris, and Berlin, in order to gain full information not only as regards meat inspection but also as to abattoir construction. This report of Dr. O'Neill, which is full of information of the greatest value and importance, was presented to the Market Committee of the Belfast corporation, and he was cordially thanked for the very great trouble he had taken in the matter. It is also a question for the Public Health Committee of Belfast. It is satisfactory to see that a by-law has been adopted (it will have to be confirmed by the Council) whereby all meat prepared outside and brought into the city must be conveyed to a market to be inspected before being used.

*Royal Visit to Belfast.*

The Lord Mayor of Belfast has received an official intimation to the effect that His Royal Highness the Prince of Wales will visit Belfast early next year, when on behalf of Her Majesty the Queen he will lay the foundation-stone of the Royal Victoria Hospital. His Royal Highness will be accompanied by H.R.H. the Princess of Wales. The exact date has not yet been fixed but the announcement of the coming visit has occasioned the utmost satisfaction. The new hospital is to commemorate the jubilee of the Queen.

*The Bacterial Method of Sewage Purification in Belfast.*

There is no subject in State medicine of greater importance at present than the purification of sewage; and it is a very pressing problem in the case of large cities or towns situated either in the interior of a country or along the coast-line. Various methods of sewage treatment have been tried, such as chemical precipitation, sewage irrigation, land filtration, or a combination of these; but with the remarkable growth of the science of bacteriology a new system of sewage treatment depending on bacterial action has arisen, and I purpose to say a few words in reference to a most interesting experiment in this direction which is at present being made at Belfast, and for my information I am largely indebted to a very scientific paper giving a report *re* Sewage Purification by the city surveyor of that place, Mr. J. C. Bretland, M.Inst.C.E. In an Act referring to the Belfast corporation passed in 1899 a clause was inserted making it obligatory to treat in some way the sewage which flows into the Lough, and after a deputation had visited certain towns in England in which bacterial treatment was being tried it was decided at a joint meeting of the improvement and public health committees to instruct the city surveyor to proceed with the construction of experimental bacteria beds in the reclaimed enclosure at the pumping-station where the sewage of over 360,000 inhabitants enters Belfast Lough. The beds, which were put in operation on August 26th, 1899, are open to the air and are four in number, two upper and two lower, the dimensions of each bed being 90 feet long by 72 feet wide at the top, 75 feet long by 57 feet wide at the bottom, with an average depth of three feet one inch. They are contained by earthen banks and to render them watertight are lined with puddled clay 12 inches thick on

which are laid bricks on the flat or old flags to prevent the filling material sinking into the puddle and to form a bed for the effluent drains. The filling material used in three of the beds (one upper and two lower) is broken bricks and in the remaining bed (an upper one) is coke. The beds are arranged at such levels that the upper one is filled from the storage reservoir when the sewage in the latter stands at a depth of at least eight feet six inches, the sewage being conveyed from the reservoir by 12-inch glazed earthenware pipes and distributed over the beds by means of V-shaped wooden troughs (four to each bed) perforated along the sides with three-quarter-inch holes. The effluent from the beds is drawn off at the bottom through ordinary field drains arranged "herring-bone" fashion and leading into nine-inch glazed earthenware pipes laid with open joints and connected with a main effluent discharge-pipe 12 inches in diameter which from the upper beds leads to the distributing troughs of the lower beds, and from the lower beds to the effluent storage space. A gauging well for measuring the capacity of the beds is also provided, as well as means of screening the sewage so as to receive any paper or other fibrous substances which may have found their way into the reservoir. The quantity of matter so passing, however, is very trifling (Report, pp. 2 and 3). With the beds filled four times per 24 hours, the two pairs of beds are capable of treating, by double contact, a quantity of sewage representing a population of about 8800 persons. The effect of this treatment varies with the nature and strength of the sewage, its temperature, and that of the external air, but, broadly speaking, the effluents produced have been satisfactory. A chemical examination showed that the average weights in five examples of screened sewage and effluents were:—

| | | | |
|---|---|---|---|
| Sewage | ... | ... | 30·64 grains per gallon. |
| First effluent | ... | ... | 17·37 ,, ,, |
| Second effluent | ... | ... | 3·50 ,, ,, |

The difference between the first and third weights represents the number of grains per gallon of solid matter which by the method of treatment under consideration is prevented from entering Belfast Lough. This weight, taking the dry weather flow as 10,000,000 gallons per day, amounts to rather more than 17 tons in 24 hours, but besides this a considerable quantity of putrescible matter in solution (23 grains per gallon in the average of the five cases) is converted in the beds into inoffensive inorganic substances. It is a remarkable fact that the removal of this great quantity of solids from the sewage is not attended with the production of a similar weight of sludge. It simply means that the difference of weights of solid matter in the sewage and effluents represents the solid matter which has been, by bacterial action, converted into inodorous and non-putrefactive liquids and gases. It does not remain behind as sludge in the beds. If the beds are worked too long at a stretch there may be sludge, but after a short period of rest it is digested and converted into inorganic substances in solution. There is no sewage smell in the beds. If the filling materials of the beds are dug up and examined there is the characteristic smell of freshly turned earth or garden mould. Half the impurity in the sewage, as a rule, is removed by the upper bed and nearly half the remainder by the lower. Dr. Lorrain Smith's report upon the sewage examined by him shows that the effect of the passage through the first bacteria bed is to deprive the sewage of about 75 per cent. of the bacteria present, while a slight further reduction results from the passage through the second bed. I will here state the change which the sewage has undergone in these bacteria beds as judged by the examination of the effluent. First, to the naked eye it has changed into a clear fluid, in many cases like ordinary drinking-water. 2. Its odour has in many specimens entirely disappeared. 3. Chemically it has been changed from a foul-smelling organic state to a form of inoffensive inorganic salts in solution. 4. The number of bacteria has been reduced in exhausting the pabulum in the sewage on which bacteria can live. It is a most curious fact that the effluent, after being discharged into the effluent storage space, apparently goes on purifying to a further extent, and this power of self-purification (which has been acquired in its passage through the bacteria beds) seems to be inherent in the effluent itself, as shown by the fact that the purification goes on even in a closely stoppered bottle. 5. Fish (the difficulty of keeping gold fish in glass globes is well known) will live in globes containing the effluent from the lower beds; and on July 9th, 1900, when members of the Improvement Committee visited the bacteria beds, they were shown a number of roach swimming in a pond of sewage effluent which had been their home since they were removed a week previously from water in Lord Deramore's park. It is found that in impure water such fish would not live more than 24 hours. The city surveyor of Belfast recommends a scheme of sewage purification for that place based largely on the methods which I have described. The works which he proposes consist of 24 upper open bacteria beds having a total net area of about 35,500 yards and a total net working capacity of about 2,500,000 gallons, together with the same number of similar "lower beds" having practically the same area and working capacity. This would require an area of 26½ acres, of which 17 acres can be found in the existing inclosure, while it is proposed to reclaim the remaining nine and a half acres from the sloblands acquired by the corporation in view of the future treatment of the sewage. Very full details are given in the surveyor's report of this proposed scheme, the initial cost of which would not be lower than £78,000. The total working expenses (two men would probably suffice to look after the beds) would be a mere fraction of the cost of treatment by chemical precipitation, to say nothing of the large initial cost of building construction required in such case. Mr. Bretland has put forward this scheme in his report in an extremely fair, judicial, and scientific spirit, and with great modesty he concludes by suggesting that "as the question is one of very great importance to the ratepayers at large, it is, I believe, desirable that some eminently skilled and independent expert should give his opinion on it before its adoption." Further scientific evidence is desirable on one most important question, and that is the effect of adopting this method of sewage purification on Belfast Lough. Unfortunately, Belfast has a very low-lying situation at the mouth of a tidal river. All the sewage of this large city (365,000 inhabitants) is discharged into the Lough in which the tide ebbs and flows. As a result those who reside on the margins of the Lough for several miles on each side are subject to the most abominable odours due to the presence of a green plant or seaweed (ulva latissima), called "sleech," which luxuriates in the sewage from Belfast discharged into the mouth of the Lough and deposited on its margins by tidal action. In former times this "sleech" was not known to dwellers on the edges of the Lough. It has become luxuriant in modern times *pari passu* with the rapid growth of the city, and the consequent increased sewage thrown into the Lough through the working of the Belfast main drainage scheme of 1887 and perhaps the present more brackish state of the water. Now we know that the sewage has become so purified in the bacteria beds that fish will live in the effluent, what we want to find out is whether the peculiar plant which I have mentioned will grow in this material which contains inorganic salts—the very substances on which vegetable life luxuriates—and whether in its growth in the effluent it will, as is stated occurs at present on the shores of Belfast Lough, exhale sulphuretted hydrogen. There is a little bay near Marino on Belfast Lough where this "sleech" grows profusely and it gives off so much sulphuretted hydrogen that the silver in the adjacent houses is blackened. This experiment of growing the "sleech" in the effluent should be made by the Belfast Public Health Committee. If it gives off sulphuretted hydrogen when grown in the effluent then the "bacterial purification" of the sewage will not do away with the stench on the shores of Belfast Lough. In an appendix to Mr. Bretland's report, Dr. Lorrain Smith, in giving the details of the bacteriological examination which he has made "on the Effect of the Bacteria Beds on the Sewage," says with true scientific caution: "The results given can only be regarded as preliminary." The Public Health Committee of Belfast might well authorise Dr. Lorrain Smith to make further investigation. Since Mr. Bretland's report was written a most important discussion on this question has taken place at the Ipswich meeting of the British Medical Association in the Section of State Medicine, August 1st, 1900. In a very able paper introducing the question Dr. A. C. Houston of London said, basing his results on experiments made for the London County Council in reference to the bacterial treatment of sewage at Crossness, that until positive evidence to the contrary were forthcoming it would be wise to regard the effluents from bacterial beds as no more safe in their possible relation to disease than

crude sewage.[1] Dr. Houston urged that a lesson to be learnt from his experiments is that the element of time or delay is an all-important factor in the problem of sewage purification by bacteria beds. He thinks that it is doubtful if any bacterial process in practical operation at present "treats" or "detains" sufficiently long the sewage to allow of the complete destruction of all pathogenic germs by bacterial agencies. Now it may turn out, on close investigation, that the construction of the bacteria beds at Belfast is different from that of those at Crossness and that there is a difference in the two places as to the length of time during which the sewage is "detained." These are points of the utmost importance and it is advisable that before spending a large sum of money on a great scheme like this—which is, it must be admitted, an experimental one—further and prolonged scientific experiments should be made of a chemical, botanical, and bacteriological nature; a course recommended, indeed, by Mr. Bretland in his extremely able and most interesting report.

Sept. 18th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

*The Physiology of the Cervical Sympathetic in Man.*

AT a recent meeting of the Academy of Medicine M. François-Franck read a paper upon some researches of M. Jonnesco and M. Floresco of Bucharest dealing with this subject. By applying to human beings the exact technique which they had employed in their experiments upon animals the Bucharest surgeons have been able to establish for the first time the identity of the immediate effects of section and excitation of the cervical sympathetic in man with those obtained by the same operations in animals. Particularly is this the case with regard to the thyroid circulation and the ocular pressure. M. Jonnesco and M. Floresco maintain besides that their experiments enable them to say that the cervical sympathetic affects the cerebral circulation by acting first as a vaso-constrictor and ofterwards as a vaso-dilator. Resection of the nerve does not cause any notable trophic changes in the region supplied by it. Before accepting these conclusions as definite M. François-Franck considers that further experimentation is necessary and that the history of patients in whom partial or complete resection of the nerve has been practised must be followed up for many months.

*Hereditary Syphilis in the Second Generation.*

M. Fournier laid before the Academy of Medicine two notes of Dr. Lemonnier. The first referred to a case in which diabetes supervened in a little girl who was suffering from hereditary syphilis but who had been cured of this by specific treatment. The second case was an obvious instance of hereditary syphilis being transmitted to the second generation. Two brothers, aged 27 years and 24 years respectively, presented undoubted signs of syphilis, the one showing its effects in the nose and the other in the leg. Neither had been exposed to specific contagion. The father showed signs of syphilis without any history of infection. He was a hereditary syphilitic. The mother was quite free from the disease.

*The Beating and Carding of Mattresses.*

The Committee of Public Health for the Seine has just recorded its approval of the recommendations contained in a report which has been drawn up by Dr. Josias as regards the beating and carding of mattresses in public places or private roads—if, that is to say, the mattresses have not been previously disinfected. The report states that very often these mattresses come direct from tenements occupied by sick persons and that the result of the operations to which they are submitted is the dispersion of contagious germs. The prefect of police, acting on the resolution of the committee, has urged the commissaries of police to carry out strictly the police order of July, 1862, which forbids the beating of wool or of hair in the public streets. Where there is no court or passage in which this work can be carried out the police commissaries are authorised to prevent it altogether except in such portion of the street as they shall appoint. M. Lepine has also given orders that the police commissaries shall see that any mattress which is to be carded shall be previously disinfected. The commissaries are also to warn carders that all wool with which they work must have been previously stoved.

*The Removal of the Cannula after Tracheotomy.*

M. Grancher read a paper on behalf of M. Moure of Bordeaux before the Academy of Medicine on this subject. M. Moure has made a study of the various causes which prevent removal of the cannula after tracheotomy. Despite the serum treatment the statistics of Bordeaux for tracheotomy are not good. It is often difficult to remove the cannula as the larynx will not remain permeable. Various reasons have been assigned for this, such as spasm of the glottis, paralysis of the dilators of the larynx, and the presence of fleshy granulations. In some children air will not pass in by the normal way before puberty. M. Moure believes that in such cases the tracheotomy has been done too high. Perichondritis may be a reason for the difficulty of removing the cannula. Whenever the cannula has been in for a long time or the trachea has been divided too high up, there will be difficulty in removing the cannula. The best place for incision is the second or third ring of the trachea. If the incision is longer than this the cannula must be left in for as short a time as possible.

## CANADA.

(FROM OUR OWN CORRESPONDENT.)

*Lodge Practice in British Columbia.*

ABOUT Dec. 1st last an agreement was entered into amongst all the medical men of the thriving city of Victoria, British Columbia, for the cessation of lodge practice in that city. This agreement was signed by all the practitioners without exception, an act which brought down upon their devoted head the anathemas of the lodge fraternity which comprises upwards of 2000 of the inhabitants. No sooner was this accomplished than the authorities of the lodges advertised for medical men to come to Victoria to do specially the combined lodge work of the city and incidentally to receive the support of the adherents of the societies. It was a stunning blow for them and very gratifying to the practitioners of Victoria that not a single medical man throughout the Dominion of Canada made any response whatever to this appeal. This fact coming to light two of those who signed the agreement immediately contracted with the lodges to do the combined work of all the societies, numbering something like 20, the emoluments running well up to $4000. Their action in thus deserting their *confrères* brought upon themselves prompt dismissal from the Victoria Medical Society. In addition to this the other practitioners of Victoria have refused to consult with either of them, stipulating that if either of the two offenders be attending a case that he be dismissed before they have anything to do with it. It is stated that the members of the lodges are very much exercised over the state of affairs and some hard things are being said against the medical men. Every night the lodge meetings are crowded and excitement is said to run high. So far the practitioners appear to have the best of the fight and it is thought that the two delinquents are sickening of their bargain with the lodges. The daily press has recently been the scene of the most active part of the campaign and each party has placed its views on the subject before the people. It is to be sincerely hoped that the Victoria medical men will stand firmly and steadfastly by their rights and come out in the end more than conquerors.

*Maritime Medical Association.*

The tenth annual session of this association was held in St. John, New Brunswick, on July 17th and 18th, under the presidency of Dr. James Christie. Mayor Daniel of St. John, himself a past president, welcomed the visitors, making feeling references to the death of the son of one of their respected members, Lieutenant Borden, a third-year student of McGill University, who had fallen on the far South African battlefield. A telegram of condolence was despatched to the Hon. Dr. Borden at Ottawa, conveying the sympathy of the members of the association. Dr. William Bayard, the "father" of the medical profession in St. John, upon whom the honorary degree of LL.D. was recently conferred by the University of

New Brunswick, delivered an admirable address upon the Prevention of the Spread of Tuberculosis. A paper on Gall-Bladder Surgery was ably presented by Dr. George Armstrong of Montreal, a subject which was further contributed to by Dr. Atherton of Fredericton. A meeting of the McGill graduates in the maritime provinces was also held during the progress of the association meeting, and it was decided to form a Maritime Graduates' Society of McGill University, with Dr. W. H. Hattie of Halifax as first president. The address in gynæcology was delivered by Dr. P. Conroy of Charlottetown, Prince Edward Island, who took for his subject, Retro-displacements. This association, which meets triennially in St. John, Halifax, and Charlottetown, will meet next year in Halifax. Dr. W. S. Muir of Truro, Nova Scotia, was elected President and Dr. G. M. Campbell (Halifax), Secretary.

*The Canadian Red Cross Commissioner to South Africa.*

Dr. George Stirling Ryerson has returned to Canada from South Africa, where he went as Canadian Red Cross Commissioner. While all England may perhaps be ringing with Mr. Burdett-Coutts's charges against the Army Medical Service in South Africa Dr. Ryerson, similarly to many of our gallant soldiers invalided home, has nothing but praise for the conduct and management of the medical part of the war. Canadians returning from their experience in the Transvaal and fresh from English hospitality express their gratitude for the manner in which they have been treated by the English soldiers and the English people. The small and scattered bands which have been lately arriving have been everywhere met by enthusiastic and admiring crowds and no one has heard a complaint of the hospital arrangements in any particular. Shortly after Dr. Ryerson's arrival in South Africa he was appointed British Commissioner at Lord Roberts's headquarters, where he had unusual facilities for observation. One of his interesting statements is to the effect that Lady Roberts's hospital for the sick and wounded soldiers at Bloemfontein is almost entirely fitted out with supplies furnished by the people of Westmount which is a suburb of the city of Montreal. Dr. Ryerson has given his opinion as to what foundation there was for Mr. Burdett-Coutts's charges, and he declares them to be absolutely incorrect. Mr. Burdett-Coutts had met Dr. Ryerson in South Africa and while there had never made any complaint to the Canadian Commissioner, although he knew that Dr. Ryerson had almost unlimited stores and money at his disposal. Dr. Ryerson states that the hospital arrangements, when one considers the difficulties that had to be surmounted, could not have been more admirable. Canada, as a portion of the British Empire, will be proud of the usage which her volunteers—for they are only volunteers—have received at the hands of the regular army of Great Britain, and of the hospitality extended at home by the English people.

*Executive Health Officers of Ontario.*

The annual meeting of this association was held at Kingston, Ontario, on August 14th and 15th, with Dr. T. V. Hutchinson (London) as presiding officer. Mr. A. McGill, B.A., analyst to the Inland Revenue Department, Ottawa, read a valuable and timely paper on the Effects of Food Preservatives on Public Health. Dr. Charles Sheard, medical health officer of Toronto, instanced several cases which had come under his notice where young children had been poisoned by re-freezing ice-cream. Dr. Cassidy (Toronto) read a very interesting paper on Tuberculosis and Means for its Cure, dealing particularly with the cheerful aspect of the question, the reported cases of cure. The address of the president was an able review of the Improvements of the Century in Sanitary Science. He condemned the use of bread tickets and paper money as carriers of infection. Dr. P. H. Bryce, secretary of the Provincial Board of Health, contributed a paper on the Education Problem as Viewed from a Public Health Standpoint. He thought that pupils were very often kept in rooms where there was not sufficient air space. He also advocated military exercises for the school-children. Dr. W. T. Connell, pathologist to Queen's University, Kingston, read a paper on Vitality of Typhoid and Diphtheria Bacilli in Milk; and another paper which called forth much and keen discussion was that of Toronto's bacteriologist, Professor Shuttleworth, on the Use of Antitoxin in Toronto Contagious Diseases Hospital. The association unanimously adopted a resolution approving of the legislation in respect to sanatoria for consumptives passed at the last session of the Ontario Parliament, and also called upon the members to coöperate with local boards of health in seeing that these sanatoria were established. Brantford was selected as the next place of meeting. Dr. W. T. Connell was elected president and Dr. P. H. Bryce secretary.

Sept. 1st.

# Obituary.

THOMAS MOORE, F.R.C.S. ENG., L.R.C.P. LOND.

THE medical profession has lost a good surgeon and his colleagues a faithful friend by the death of Mr. Thomas Moore, of Lee-terrace, Blackheath, who passed away on Sept. 6th after a few hours' illness while on a visit to Kennington, near Ashford. The deceased gentleman, who was in his sixty-second year, was the second son of the late Mr. Edward Moore of Halesowen, Worcestershire, received his medical education at St. Bartholomew's Hospital, was admitted a Licentiate of the Royal College of Physicians of London in 1865, and obtained the Fellowship of the Royal College of Surgeons of England in 1867. At the time of his death Mr. Moore held the posts of senior surgeon to the Miller Hospital at Greenwich, medical officer of health of Eltham, consulting surgeon to the Brighton Children's Hospital and the Petersfield Cottage Hospital, and treasurer of the Roentgen Ray Society. For the last 20 years Mr. Moore had practised at Blackheath, previously to which he had been at Petersfield, where he founded the Cottage Hospital. Of Mr. Moore it may truly be said that his heart was wholly in his profession and at a time when many men think of "slacking off" and taking a well-earned rest he worked hard at bacteriology and Roentgen rays and made himself proficient in these latter-day sciences. He established a Roentgen ray department at the Miller Hospital which he equipped and superintended till the day of his death. As honorary secretary of the Blackheath Amateur Operatic Society he had been instrumental in raising over £1000 for the Miller Hospital. Mr. Moore was beloved by his patients, rich and poor; he never failed to respond to any call made upon him and he declined to leave his patient until he felt he had done all he could. He was an ex-president of the West Kent Medico-Chirurgical Society, to which he contributed a large number of useful papers. He was also a member of the West Kent Microscopical and Natural History Society. Mr. Moore contributed several papers to THE LANCET, among which may be mentioned a case of poisoning by strychnine treated successfully with tincture of opium and one of lithotomy (published in 1872), one of herniotomy (1874) and one of recovery from rabies (1880).

# Medical News.

UNIVERSITY OF DURHAM.—At the Second Examination for the degree of Bachelor in Medicine, held at the College of Medicine, Newcastle-upon-Tyne, in September, the following candidates satisfied the examiners:—

*Anatomy, Physiology, and Materia Medica.—First-class Honours:* William Henry Peacock, College of Medicine, Newcastle-upon-Tyne. *Second-class Honours:* Auburn Lawrence Wilkinson, Arthur Gibson Dunn, and Daniel Richard Guns, College of Medicine, Newcastle-upon-Tyne; and Margaret Douglas French, London School of Medicine for Women. *Pass List:* Ernest George Annis, M.R.C.S., L.R.C.P., D.P.H., Guy's Hospital; Edmund Howard Barrett, M.R.C.S., L.R.C.P., St. Mary's Hospital; Ambrose Harold Bateman, St. Bartholomew's Hospital; Walter Donald Carruthers, Birmingham University; John Wilfrid Caton, Guy Rowland East, and Arthur Henry Fullerton, College of Medicine, Newcastle-upon-Tyne; Philip Gell Garrett, M.R.C.S., L.R.C.P., D.P.H., Middlesex Hospital; Francis Jollie Gowans, Marshall Haver, and William George Thomas Hepplewhite, College of Medicine, Newcastle-upon-Tyne; William Hughes, Edinburgh School of Medicine; Wharram Henry Lamplough, Birmingham University; Charles Robert Lease, College of Medicine, Newcastle-upon-Tyne; Ernest James Miller, Cooke's School of Anatomy and University College, London; George Edward Victor Morris, Birmingham University; Christie Mûthûswamy-Anthony, Guy's Hospital; Thomasina Georgina Prosser, Frederick William Ritson, and Joseph Collingwood Stewart, College of Medicine, Newcastle-upon-Tyne; Alexander Minter Watts, M.R.C.S., L.R.C.P., University College, London; and John Robert Wylie, College of Medicine, Newcastle-upon-Tyne.

NEW BATHS AT CHELTENHAM.—The new baths erected in Cheltenham by the corporation were formally opened by the Mayoress on Sept. 10th. The cost of the building, which is luxuriously fitted and furnished, is nearly £10,000.

DIPHTHERIA AT PILL.—At the meeting of the Long Ashton (Somerset) Rural District Council, held on Sept. 11th, Mr. Fuller, the medical officer of health, stated that there were at present about 100 cases of diphtheria in the village of Pill.

BRISTOL MEDICAL CHARITIES.—A "collecting dog" at Bristol, known as "Punch No. 2," has during the past six years collected over £100 for the local medical charities. His father, "Punch No. 1," was also a hospital collector, and between them the two dogs have collected 48,579 coins.

POISONING BY FUNGI.—An inquest was held at Devonport on Sept. 13th upon the bodies of two lads, aged 11 and nine years respectively. On Sept. 8th they had partaken of apples, acorns, blackberries, and what they had considered to be mushrooms, and were afterwards taken ill with symptoms of gastric irritation. The younger one died on Sept. 11th and the elder one on the following day. The jury found that the deaths were due to eating noxious fungi.

NEW WATERWORKS AT LILLINGTON.—The ceremony of formally opening the Leamington corporation's recently constructed waterworks at Lillington took place on Sept. 5th in the presence of a large assembly of interested persons. A well has been sunk to the depth of 170 feet and an additional yield of 450 000 gallons per day has been obtained which it is estimated will provide an adequate supply in perpetuity.

OPEN-AIR TREATMENT OF PHTHISIS.—It was reported at the last meeting of the managers of the Poplar and Stepney Sick Asylum district that their proposal to hold a conference of Poor-law administrators for providing accommodation for the open-air treatment of phthisis had been successful, and it was estimated that representatives of about 60 unions and parishes would attend the conference to be held in the ensuing month at the St. Martin's Town-hall, Charing-cross-road, London, W.C.

ROYAL ALBERT HOSPITAL, DEVONPORT.—The managing committee of this hospital has just issued an urgent appeal for subscriptions towards the new buildings which were commenced last May. It is proposed to erect a "nurses' home" and an isolation ward and to make various internal improvements. It is not intended to increase the number of in-patients as the annual income of the institution is at present insufficient to meet the ordinary expenditure. The committee require £5500 and at present only £1519 of this sum have been received.

MEDICAL OFFICERS OF HEALTH AND LOCAL AUTHORITIES.—At the meeting of the Penzance Town Council, held on Sept. 12th, it was decided that the medical officer of health (Mr. R. D. Boase) should be re-appointed for one year only, instead of for three as on former occasions. The member who proposed this new arrangement said "that medical officers of health throughout the country were very much disposed to set aside the authority appointing them and to look to the Local Government Board and county councils as the authority to whom they were responsible." This, he remarked, "was very wrong," and he further added that "if they appointed any officer for a permanent tenure they were appointing not a servant but a master, and this was strongly to be objected to."

BRISTOL GENERAL HOSPITAL.—The half-yearly general meeting of the supporters of this institution was held on Sept. 10th under the presidency of Mr. J. S. Fry. The financial report showed that there was a considerable decrease in donations and also in the collections in places of worship. The legacies had also shown a diminution. The expenditure was less than for the corresponding period of last year. 1222 in-patients had been admitted during the first half of 1900, as compared with 1140 for the corresponding period of 1899. The average daily number of in-patients was 162, as against 170 in the previous year. The chairman stated that large alterations and improvements were contemplated in the out-patient department and added that the committee had also in view the introduction of electric light in the hospital.

DIPHTHERIA IN LEICESTER.—The report of the medical officer of health of the borough of Leicester for the week ending Sept. 15th shows that of 82 fresh cases of infectious disease reported during the week diphtheria claimed 58 and nine deaths.

THE ONTARIO MEDICAL LIBRARY ASSOCIATION.—The thirteenth annual meeting of this association was held in the Library Rooms, Toronto, on June 28th, with Dr. J. F. W. Ross, the president, in the chair. The association approached the legislature of the province recently asking that a grant should be given annually similar to that already extended to the Law Association, and it is gratifying to learn from the president that in the near future this is likely to become a fixture. Books from this library are sent to medical men throughout the province of Ontario on their paying express charges both ways and returning them within two weeks, a privilege secured to the profession at large through the Ontario Medical Council, in whose building in Toronto the library is located. The curator, Dr. N. A. Powell, reported that 161 new volumes and three cases still unopened had been added to the library during the past year. Dr. Powell is a member of the American Association of Librarians and is enabled to secure duplicates from other libraries in exchange. The association has now something like 400 members, practitioners from the city and throughout the province, who contribute an annual fee of $2 00. At a meeting of the board of directors held on July 4th Dr. Ross was re-elected president, Dr. H. J. Hamilton secretary, and Dr. N. A. Powell curator.

# Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to* THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

BOASE, R. D., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer of Health for Penzance.

BRODRICK, C. C., L.R.C.P., L.R.C.S., Edin., has been re-appointed Medical Officer of Health for Tavistock.

CLARKE, W. J., M.R.C.S., has been appointed Medical Officer for the Second Sanitary District of the Newbury Union, vice M. H. S. Palmer, resigned.

CLEMENGER, A. N., L.S.A., has been appointed Medical Officer and Public Vaccinator for the Slaidburn Sanitary District of the Clitheroe Union.

DAVIES, F. W. S., M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Anæsthetist to the Cardiff Infirmary.

DODD, NOEL, L.R.C.P. & S. Edin., has been appointed Junior Assistant House Surgeon to the Stockport Infirmary.

GODSON, J. H., M.B., B.C. Camb., D.P.H., has been re-appointed Medical Officer of Health by the Cheadle and Gatley Urban District Council.

GRUBB, R. T., L.R.C.P. Edin., M.R.C.S., has been re-appointed District Medical Officer, Epping Union.

HALLAM, H., L.R.C.P. Lond., M.R.C.S., has been re-appointed Assistant Medical Officer for Eccleshall Workhouse.

HODGSON, J. F., M.B., Ch.B. Vict., has been appointed Assistant House Surgeon to the Oldham Infirmary.

HOSKINS, W., M.B., C.M. Aberd., has been re-appointed District Medical Officer, Epping Union.

HOUSLEY, J., M.D. St. And., M.R.C.S., D.P.H. Glasg., has been re-appointed Medical Officer of Health for the Rural Sanitary District of Retford.

HOWELLS, J., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Abercrave Collieries, Brecon, vice T. Richards.

PEARCE, GEO. HARPER, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been re-appointed Medical Officer of Health by the Darton Urban District Council.

POTTS, G., L.R.C.P. & S. Edin., has been appointed Second Assistant Medical Officer to the County Asylum, Dorchester, vice C. E. P. Forsythe.

PRATT, ELIDON, M.D. Lond., L.R.C.P., M.R.C.S., has been appointed Honorary Anæsthetist to the Cardiff Infirmary.

SOUTHAM, F. A., M.B. Oxon., F.R.C.S. Eng., has been appointed Honorary Surgeon to the Manchester Cancer Pavilion and Home.

STEINHAEUSER, J. R., M.B., B.S. Lond., L.R.C.P., M.R.C.S., has been re-appointed Medical Officer of Health by the Lewes Town Council.

THORMAN, W. H., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer and Public Vaccinator for the Kirkburton Sanitary District, Huddersfield Union, vice W. P. T. Daniel, resigned.

TURNER, G. G., M.B., B.S., M.R.C.S., L.R.C.P., has been appointed Surgical Registrar to the Royal Infirmary, Newcastle-on-Tyne, vice J. D. Wardale, resigned.

WEEKS, C. C., L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the Metropolitan Borough of Lewisham.

WOOD, C. G. RUSS, M.R.C.S., L.R.C.P. Lond., has been appointed Surgeon to the Eye, Ear, and Throat Hospital for Shropshire and Wales, Shrewsbury, vice W. Charnley, deceased.

WRIGHT, G. A., M.B. Oxon., F.R.C.S. Eng., has been appointed Honorary Surgeon to the Manchester Cancer Pavilion and Home.

# Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index).*

BIRKENHEAD BOROUGH HOSPITAL.—Honorary Surgeon.

BOURNEMOUTH NATIONAL SANATORIUM FOR CONSUMPTION AND DISEASES OF THE CHEST.—Resident Medical Officer. Salary commencing at £10 per working month, board, residence, and washing (no alcohol) provided.

BRADFORD ROYAL INFIRMARY. — Dispensary Surgeon, unmarried. Salary £100 per annum, with board and residence.

CITY HOSPITAL FOR INFECTIOUS DISEASES, Newcastle-upon-Tyne.—Resident Medical Assistant for one year. Salary £60, with board, lodging, and washing.

COUNTY ASYLUM, Chester.—Junior Assistant Medical Officer, unmarried. Salary £130 per annum, rising £10 yearly to £160, with board (no liquors), lodging, and washing.

COUNTY ASYLUM, Lancaster.—Assistant Medical Officer. Commencing salary £125 per annum with the usual allowances.

# Births, Marriages, and Deaths.

## BIRTHS.

ATKINSON.—On Sept. 11th, at Puddington, Devon, the wife of J. M. Atkinson, M.B. Lond., of Hong-Kong, of a son.

CHURCHOUSE.—On Sept. 12th, at Long Buckby, the wife of W. J. Franklin Churchouse, L.R.C.P., of a son.

LISTER.—On Sept. 16th, at Rose Hill, Totteridge, the wife of W. T. Lister, F.R.C.S., of a son.

MAPLETON.—On Sept. 10th, at Goudhurst, Kent, the wife of G. H. Mapleton, M.B., of a daughter.

MIDDLEMASS.—On Sept. 18th, at Ryhope, Sunderland, the wife of Jas. Middlemass, M.D., F.R.C.P.E., of a son.

NASH.—On Sept. 16th, at Accrington, Mary Monica, the wife of Elwyn H. T. Nash, M.R.C.S., L.R.C.P., of a daughter.

PALEY.—On Sept. 17th, at Brunswick-place, Hove, the wife of F. J. Paley, M.D. Lond., of a son.

## MARRIAGES.

EWAN—FERRIER.—On Sept. 12th, at St. Mary's, Castletown, Isle of Man, W. J. S. Ewan, M.B., C.M., son of the Rev. W. Ewan, of F.C. Manse, Fyvie, N.B., to Mary, daughter of the late Canon Ferrier.

GEDDES—KOEK.—On the 13th inst., at St. Edmund's, Sedgefield, J. W. Geddes, M.B., C.M., of the Durham County Asylum, to Ethel Beatrice Marie, youngest daughter of the late E. Koek, Esq., of Singapore.

GODSON—MAYALL.—On Sept. 12th, at St. Thomas's Church, Werneth, Oldham, Alfred Henry Godson, B.A., M.B., B.C. Cantab., F.R.C.S. Eng., eldest son of Alfred Godson, of Cheadle House, Cheadle, Cheshire, to Mary Elizabeth, youngest daughter of the late Samuel Mayall, J.P., of Springside, Lees.

THEOBALDS—LEMPRIERE.—At Saint Mary's Church, Wargrave, on the 13th inst., by the Rev. H. M. Ellis, rector of Exbury (brother-in-law of the bride), assisted by the Rev. A. Austen Leigh, vicar of Wargrave, and the Rev. F. B. Hope, Arthur J. A. Theobalds, M.B., C.M., Gaunt Cottage, Wargrave, to Effie, second daugther of the late Captain Lempriere, South Hampshire Regiment, and of Mrs. Herbert Lempriere, The Croft, Wargrave.

## DEATHS.

COPELAND.—On Sept. 16th, at Staindrop, Co. Durham, William Copeland, M.B., C.M. Edin., son of the late William Copeland, M.R.C.S., aged 54 years.

COURTEEN.—On Sept. 17th, at 99, Park End-road, Gloucester, Raymond Courteen, M.B., M.R.C.S., L.R.C.P.

HEWAN.—On Sept. 17th, at 23, George-square, Edinburgh, Ethel Jane, wife of John Hewan, M.R.C.S., L.R.C.P., of Assam, India.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Short Comments, and Answers to Correspondents.

## "A SUBSTITUTE FOR BRANDY."

WE have received a long letter from the friend who gave Mrs. Oliver the prescription for the substitute for brandy. The writer does not wish to disclose her name unless her letter is printed in its entirety, and this we are unable to do, but we subjoin the principal portions thereof.

"Strongest tincture of ginger, sal volatile, and chloric ether—granting that these three drugs are as alcoholised as brandy I still claim that the mixture is a desirable substitute for brandy. For it must be distinctly understood that temperance reformers have no quarrel with the drug alcohol provided it be kept in its proper place side by side with the other poisonous drugs that find their legitimate place in the doctor's dispensary. If alcohol were kept there and simply used as other drugs are used in combating disease there would be no need for temperance societies.

* * * *

And I would urge first our right to protest against being sent to the publican and the wine merchant for our medicine. To say the least, it is a slipshod way of performing an important duty. And its results are often direful. Patients ought not to be subjected to such risks at the hands of their medical advisers. If they need alcohol, why should they not get it in its pure form as rectified spirits of wine made up as a mixture from the chemist; or if there should be any other constituent in these public-house drinks that is considered desirable for the patient, surely the doctor's professional knowledge is sufficient to enable him to prescribe it in some other form. To tell a poor mother to give her ailing daughter gin, or to tell the rich mother to give her child port wine two or three times a day, seems to my lay mind a most unfair way of treating cases, and a most irresponsible and dangerous way. For how does the poor woman know that she is giving her girl, not only alcohol, which comes to have a deadly fascination for her ere long perhaps, but also, it may be, fusel oil, turpentine, or some other horror added? And how does the wealthy mother know what the 'port wine' would reveal, if analysed, or whether it contained even a particle of grape-juice?

"We contend that the 'substitute for brandy' given in the article quoted from is a thousand times better and safer than brandy. It is a medicine pure and simple, kept as such in the medicine-cupboard to resort to *only* in emergencies, whilst 'nips' of brandy may be resorted to on many a plausible occasion when there is no crying need for it, but only a craving for its flavour and transient stimulating effect. And unlimited supplies of brandy can be got at the nearest public-house or licensed grocers, alas!

"I shall continue to give broadcast this 'substitute for brandy' with as much confidence as I gave it to Mrs. Oliver, having tested its efficacy for many years without seeing any evil result of its use."

We give the writer of the above every credit for being perfectly honest in her desire to promote the cause of temperance, but she altogether mistakes the reason why brandy and port wine are ordered. It is not on account of the alcohol which they contain so much as on account of the ethers. Therefore, giving rectified spirit would not in the very least be the same thing as giving old brandy. But we need not pursue this line of argument. Our contention is still the same. The temperance reformer objects to brandy because it is alcoholic and because it can be obtained at any public-house. As a substitute for this she recommends a cordial which has some 80 per cent. of alcohol as against 50 per cent. in brandy, which any chemist will "make up for 6d." and which she will continue to give "broadcast." This, to our minds, is not the line on which temperance reform should go.

## UNQUALIFIED ASSISTANTS.

*To the Editors of* THE LANCET.

SIRS,—In view of the recent regulations regarding unqualified practice and the covering of such by qualified men, I am desirous of knowing if the undermentioned cases are breaches of the regulations of the General Medical Council. X is a qualified man who has during the past two years had a succession of dispensers or unqualified assistants. On August 21st, 1898, the then "assistant" attended a case of midwifery and all the after-attendance was done by him. X, the principal, passed this man off as thoroughly qualified and when he left his service assigned as a reason that Dr. So-and-So was going in for his "Fellowship." During the summer X was asked to visit a case which turned out to be one of a dangerous and infectious nature. On three dates the dispenser or unqualified assistant made all the visits. And Y, a qualified man, made a supplementary visit on the last occasion on behalf of X. X was also sent for to see a patient of another practitioner, but the visit was made by the then "assistant," who was in sole charge of the practice, X being away from home. The man who attended the two latter cases was engaged as a dispenser at a weekly wage of 15*s*. He made visits with the help of X's trap, attended midwifery cases, and consulted in the surgery, as can be easily proved. His predecessors (unqualified assistants) visited patients for Y and Z—qualified men—during their absence from home or when they were ill.

I am, Sirs, yours faithfully,

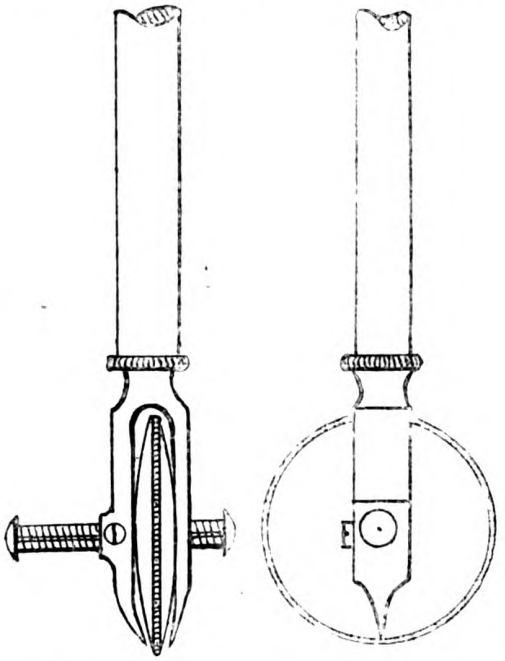
August 20th, 1900. JUSTITIA.

*** The facts as stated constitute "covering," and if they are accurate and were proved against X before the General Medical Council would be very likely to lead to his removal from the Medical Register.—ED. L.

## MEASUREMENT OF TUMOURS.

*To the Editors of* THE LANCET.

SIRS,—The instrument called an opisometer used for measuring distances on maps might be applied by medical men for the measurement of swellings and tumours of various sorts with a view to recording their varying dimensions from time to time. Two small lines might



be marked on the skin with nitrate of silver and the opisometer rolled from one to the other and then rolled back upon an accurate scale. In this way minute alterations of bulk and contour might be recorded. It might also be used in operations on the cranium. The instrument is fully described by W. F. Stanley in his book on drawing instruments.

I am, Sirs, yours faithfully,

Bartholomew Villas, N.W., Sept. 18th. RICHARD INWARDS.

## THE PIGMENTATION OF THE FÆCES.

*To the Editors of* THE LANCET.

SIRS,—I cannot find any mention of the following fact in books of reference. Normal fæcal matter will lie in water without imparting any colour thereto, but sometimes the water rapidly becomes deeply coloured either of a rich yellow or brown tint. Can this pigment be an excess of stercobilin, or is it some other pigment? Has the phenomenon any pathological significance? I should be glad to have the opinion of your readers on the matter.

I am, Sirs, yours faithfully,

Sept. 19th, 1900. F.I.C.

## COSMETIC SURGERY.

IN the September number of the *Royal Magazine* is an account of what is called "A Beauty Factory" in the United States, and a correspondent who draws our attention to this article wishes to know if the marvels therein described are limited to the American continent or are also attainable in England. On the whole it may be said that most of the operations referred to in the article are frequently performed in England and we may be permitted to retain a healthy scepticism as to the possibility of some of the others. The article describes the removal of a scar by means of electricity so that no trace of the cicatrix was left. We may be permitted to doubt the possibility of this performance, though there is no difficulty in releasing adherent scars so that they are much less noticeable. No doubt some of the obscurity in the description in the article referred to is due to the fact that the narrator is not a member of the medical profession; for instance, we are told that

"some substance was placed on the bones to cement them together." This occurs in the description of an operation for "building up a nose with a sunken bridge." Even in England dimples can be produced at command, but whether it is justifiable to use a general anæsthetic for such an operation is rather doubtful. In all these cosmetic operations the immediate result is not what has to be considered, but rather the result after a few years, and in no small proportion of the cases the final condition is by no means all that could be desired.

## THE SMOKE NUISANCE.

*To the Editors of* THE LANCET.

SIRS,—Would a medical officer of health be justified in going into court and swearing that smoke issuing from brick-kilns that are situated within 10 and 20 feet of inhabited houses and a large board school was a nuisance injurious to health? and upon what grounds could he (the medical officer of health) prove it?

I am, Sirs, yours faithfully,
X. Y. Z.

Sept. 14th, 1900.

*** Nuisance from brick kilns is due to the smoke and sulphurous fumes issuing from the kilns. These fumes are irritating and lead to the closing of windows and thus are prejudicial to the inmates. It must be recollected that for the purpose of abatement an emanation must be a nuisance or injurious to health; it need not be both. Even if injury to health cannot be proved a kiln within the distance stated is probably a nuisance. Such emanations, however, frequently give rise to headache.—ED. L.

## EDUCATIONAL AID FOR MEDICAL STUDENTS.

*To the Editors of* THE LANCET.

SIRS,—I shall be greatly obliged should you kindly inform me through the medium of THE LANCET if there exists in the medical profession a society or some such a body having as its object the granting of pecuniary assistance to deserving men who through no fault of their own may be unable to continue their studies through lack of means, such assistance being, of course, granted on particular terms and after recommendation? Thanking you in anticipation for the favour of your reply in THE LANCET of this week,

I am, Sirs, yours faithfully,
DANIEL.

Sept. 16th, 1900.

*** We know of no such society in the medical profession. Tancred's Charity assists students in divinity, law, and physic who are "not capable of obtaining the education without assistance of this or a like charity." Our correspondent might apply for particulars of this charity to Mr. George Edgar Frere, clerk to the Governors and Trustees, 28, Lincoln's Inn-fields, W.C.—ED. L.

## THE LIFE ASSURANCE MEDICAL OFFICERS' ASSOCIATION.

*To the Editors of* THE LANCET.

SIRS,—I am much interested in insurance work and am local referee for some half-a-dozen insurance companies. If you could give me any nformation about the "Life Assurance Medical Officers' Association" I would esteem it a favour.

I am, Sirs, yours faithfully,
PROVINCIAL.

Sept. 12th, 1900.

*** The Life Assurance Medical Officers' Association was founded in 1893. The President is Sir Hermann Weber and the secretary is Dr. H. Mackenzie, 59, Welbeck-street, W.—ED. L.

## "A CONVALESCENT HOME FOR UPPER-CLASS CHILDREN."

MR. F. JAFFREY, F.R.C.S. Eng., L.R.C.P. Lond., writes to us in answer to Dr. A. G. Barrs's letter which appeared in THE LANCET of Sept. 15th, giving the address of a convalescent home—Heather Brow, Headly Hill, near Liphook, Hants. The home is kept by Miss Calvert.

## A POINT IN DIAGNOSIS.

*To the Editors of* THE LANCET.

SIRS,—Can any reader of THE LANCET suggest treatment for the following case? A boy, aged 15 years, complains of sneezing in the mornings but at no other times. Local examination of the nose reveals nothing abnormal. I have used the electro-cautery, local applications of cocaine, tonics, &c., but without any effect.

I am, Sirs, yours faithfully,
Q. R. S.

Sept. 14th, 1900.

## WANTED—A HOME FOR AN EPILEPTIC.

*To the Editors of* THE LANCET.

SIRS,—I should feel obliged for information as to a home or institution where a clergyman (Roman Catholic) can be accommodated under the following circumstances. He had, I understand, marked epileptiform seizures three and two years respectively, none in the interval. After the first memory was affected slightly—after the second very badly. Since then attacks have been more frequent—every two months or oftener. There is a peculiar post-epileptic condition with marked delusions. He is never violent, never irrational, and knows that what he sees must be creations of his own fancy. He is persuaded, however, that the devil appears to him and means to carry him off. He has an allowance of about £2 weekly.

I am, Sirs, yours faithfully,
S.

Sept. 17th, 1900.

## "THE SCHEDULING OF CARBOLIC ACID."

IN commenting upon the commercial resistance which is being brought forward to prevent the scheduling of acids as poisons a provincial paper remarks that "The National Union of Mineral Water Manufacturers, which represents a numerous body of manufacturers in England and Wales, who are of course the largest organised consumers of carbolic acid, has petitioned the Home Office begging that the official intention may be persisted in." This resolution must surely have related to the fact that carbolic acid was largely sold in ginger-beer bottles, a state of things which rendered the control of the sale of carbolic acid very desirable, rather than to mineral water makers being "the largest organised consumers of carbolic acid." Or did the writer mean carbonic acid?

## BOOKS REQUIRED.

*To the Editors of* THE LANCET.

SIRS,—I shall be much obliged for information as to the best text-books on the following subjects: (1) Practical Physiological Chemistry, and (2) Practical Experimental Physiology. Thanking you in anticipation,

I am, Sirs, yours faithfully,
MALEBRANCHE.

Sept. 17th, 1900.

*** A list of books will be found in THE LANCET of Sept. 1st, 1900, under the heading "The Student's Library."—ED. L.

## THE QUESTION OF A TRANSFER.

*To the Editors of* THE LANCET.

SIRS,—I shall be grateful for an opinion on the following points. A and B are partners in a middle-class practice of £2000 a year. A is going to retire and so B is going to take in C on the understanding that he pays two years' purchase of the gross receipts on the average of the last three years. B is to occupy A's house, a large one and associated for 20 years with the practice, while C is to occupy B's house, a smaller one. To what extent should the purchase price be affected (1) by B not occupying A's house but another one of the same rental close by; and (2) by A remaining in the neighbourhood as consulting physician?

I am, Sirs, yours faithfully,
AJAX.

Sept. 18th, 1900.

*** Our correspondent should obtain advice from some competent solicitor or agent.—ED. L.

## THE RIGHT TO A COCKADE.

*To the Editors of* THE LANCET.

SIRS,—I am a surgeon-lieutenant in the Volunteers. Is my coachman entitled to have a cockade in virtue of my commission? If so, is there any annual fee to be paid to Government as a tax?

I am, Sirs, yours faithfully,
VERDANT.

Sept. 19th, 1900.

*** Anyone holding Her Majesty's commission may use a cockade. It is not an armorial bearing and no tax has to be paid for its use.—ED. L.

---

*Mr. M. F. Cahill.*—It is a little difficult to mention any French works on general surgery exactly corresponding to the works to which our correspondent refers, but we may mention as corresponding to the larger work, "Nouveaux Éléments de Pathologie Chirurgicale" (Paris, 1898), by Gross, Rolmer, &c., in two volumes. A very useful book is "Traité de Chirurgie d'Urgence," by Lejars, Paris. A second edition has recently appeared.

*Mr. G. Reginald Jones.*—The Liverpool Home for Epileptics receives patients at a charge of from 7*s.* 6*d.* per week. The honorary secretary is Mr. W. Grisewood, 2, Exchange-street East, Liverpool. We do not know of any free home.

*Namron.*—If the card is only given to patients on their attending at the surgery we do not think that it could be considered "a form of advertising."

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

---

**During the week marked copies of the following newspapers, have been received:** *Lisburn Standard, Gainsborough Leader, Bradford Observer, Baker's Record, Western Morning News, Leek Times, Blackburn Weekly Standard, Walsall Advertiser, Cambridge Chronicle, Dundee Advertiser, Morning (London), Leeds Mercury, South Wales News, Vegetarian, Birmingham Daily Post, Dublin Daily Express, Lancaster Standard, Liverpool Daily Post, Lancashire Daily Post, Scotsman, Clifton Chronicle, Sheffield Daily Telegraph, Leicester Daily Post, Leamington Spa Courier, Normanton Herald, Times of India, Pioneer Mail, Citizen, Leeds Mercury, Builder, Bristol Mercury, Architect, City Press, Yorkshire Post, Newbury Weekly News, Huddersfield Examiner, Sanitary Record, Hertfordshire Mercury, Liverpool Journal of Commerce, Reading Mercury, St. Andrew's Citizen, Monmouth Beacon, Stamford Guardian, Mining Journal, Newcastle Daily Chronicle, Surrey Advertiser, Cheshire Daily Echo, Local Government Chronicle, Bournemouth Visitors' Directory, Scarborough Post, Leighton Buzzard Reporter, Evening Telegraph (Dublin), Nuneaton Observer, &c., &c.*

## OPERATIONS.

### METROPOLITAN HOSPITALS.

**MONDAY (24th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.).

**TUESDAY (25th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

**WEDNESDAY (26th).**—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.)

**THURSDAY (27th).**—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.) University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

**FRIDAY (28th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

**SATURDAY (29th).**—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

**At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.**

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**MONDAY (24th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. W. Anderson: Consultation. (Skin.)

**TUESDAY (25th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. C. T. Williams: Consultation. (Medical.)

**WEDNESDAY (26th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—5 P.M. Dr. A. E. Sansom: Clinical Lecture.

**THURSDAY (27th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. Hutchinson: Consultation. (Surgical.)

**FRIDAY (28th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. StClair Thomson: Consultation. (Nose and Throat.) 5-7 P.M. Mr. J. Griffith: Class. Practical Ophthalmology. Demonstration I.

## EDITORIAL NOTICES.

**It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.**

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Lectures, original articles, and reports should be written on one side of the paper only,* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1900, which was completed with the issue of June 30th, and the Title-page to the Volume, were given in THE LANCET of July 7th.

### VOLUMES AND CASES.

VOLUMES for the first half of the year 1900 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

| FOR THE UNITED KINGDOM. | | TO THE COLONIES AND ABROAD. | |
|---|---|---|---|
| One Year ... ... ... | £1 12 6 | One Year ... ... ... | £1 14 8 |
| Six Months ... ... ... | 0 16 3 | Six Months ... ... ... | 0 17 4 |
| Three Months ... ... | 0 8 2 | Three Months ... ... | 0 8 8 |

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France,—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

# An Address
ON
# THE TREATMENT OF TYPHOID FEVER.

*Delivered before the Wigan Medical Society on Dec. 14th, 1899,*

BY JAMES BARR, M.D. GLASG., M.R.C.P. LOND.,
PHYSICIAN TO THE LIVERPOOL ROYAL INFIRMARY AND LECTURER ON CLINICAL MEDICINE AT UNIVERSITY COLLEGE, LIVERPOOL.

GENTLEMEN,—I feel honoured by your special request that I should deliver an address on the treatment of typhoid fever, and I shall as far as possible comply with your instructions that I should describe a method of treatment which can be readily carried out in private practice—perhaps shorn of the elaborate details which I have elsewhere advocated.[1] This will not very much curtail the scope of the address, as, in my opinion, every system of treatment can be carried out in private if you have got efficient nurses, but where you cannot rely on your nursing arrangements I should strongly recommend you to send such patients to a hospital. There is nothing more annoying to a medical attendant than to find his patient imperfectly nursed at a late stage of the disease, when perhaps it is im ossible to remove him.

I am sure you do not wish me to attempt to describe any system of treatment "made easy" which is so dear to the practical English mind. There is no straight path in the treatment of typhoid fever, so you will excuse me for not attempting to describe one. There are hundreds of men who would prescribe the latest synthetical product from Germany, of which they know nothing, on the authority of a chemist's testimonial—which, perhaps, was well paid for—who would not undertake the labour attending the use of cold baths which have undoubtedly diminished the o rtality in this disease. Now I do not approve of Brand's system as a routine treatment, not because it is troublesome but because it is, as Sir William Gairdner says, too much of a battledore-and-shuttlecock treatment—on the one hand cold baths, and on the other alcohol—and because the same end can be better attained by less heroic measures.

The treatment of disease is an applied art. Scientific methods may be laid down, but the application is an art and there is no disease where there is greater scope for the display of our skill than in the treatment of typhoid fever; the ever-varying picture and the danger signals ahead afford an interesting study which should well repay the diligent inquiry of every practitioner. In the treatment of typhoid fever death seems to dog some men's footsteps. This is not because they do not know the disease as well as others do, but because they are not artists. They do not clearly see the picture which nature has unfolded; their perspective is too limited and they have no eye for detail.

As a correct diagnosis is the first part of treatment I should like thus to have commenced my address, but in the time at my disposal this would carry me too far afield. I must therefore content myself by pointing out the necessity for an early recognition of the disease, and this note of warning is especially necessary in the present day as there is now a great tendency to leave the diagnosis to the bacteriologist. In my opinion in nine cases out of 10 the diagnosis should be made by the third day, whereas if you wait for Widal's reaction you will never have an opinion before the fifth day, and frequently the patient will be on the high road to recovery, or perhaps the grave, before the diagnosis has been made for you. It is an excellent confirmatory test and as such should not be neglected; moreover, as it shows a reaction on the part of the patient against the typhoid bacilli it has some prognostic value. As a very early test I prefer Ehrlich's diazo-reaction of the urine which, although present in some other febrile affections, is never so pronounced as in typhoid fever. When the patient is improving this test gradually disappears, but Widal's, or rather Grünbaum's, reaction becomes more marked.

When you are called in to see a patient with severe headache, suffused face, moderate fever, perhaps vomiting or other gastro-intestinal symptoms, chilliness, and pains in the limbs, do not jump at the conclu-ion that he has got influenza and commence to dose him with antipyrin, phenacetin, or acetanilid. These drugs do a great deal of mischief in this disease and are wholly unnecessary for any other. In my opinion it is a great pity that they were ever invented.

We will suppose that you have seen the patient during the first day of the fever, which only occasionally happens, but even then you will probably get a history of some prodromal symptoms during the incubation period of the previous fortnight. There have been general malaise, lassitude, inaptitude for business, and perhaps one or two slight attacks of diarrhœa which may have been injudiciously checked. During the first day or two you may call the disease influenza, or a cold, or a chill, or whatever else you like, but, in my opinion, it is much better not to give it a name unless you feel confident as to the nature of the affection with which you have got to deal. Your thermometer will show you that the patient is feverish and so you should send him to bed after a warm bath. For any febrile process it is not necessary that he should be overclothed—nay, it is better that no method should be adopted further to elevate the temperature. Whether there be diarrhœa or constipation he should get a good dose of calomel to be followed by a saline draught on the following morning. If there be vomiting he should have three or four tumblerfuls of hot water to wash out the stomach. If there be much headache, restlessness, or sleeplessness he should get 10 grains of Dover's powder which may be combined with 10 grains of salicylic acid or salol and repeated as often as may be necessary. This should carry you on to the third day, by which time, I presume, the diagnosis will have been made, though in some cases it may require further confirmation.

## PROPHYLAXIS.

Prevention is better than cure and typhoid fever is a preventable disease, but unfortunately it is one which is not prevented. By giving us a fresh water-supply sanitary authorities have lessened or almost abolished widely spread epidemics, but as an endemic in many large centres of population it is as prevalent and of as severe a type as it was a quarter of a century ago. Although the type is now as severe as ever it was, the death-rate during this period has been diminished at least 50 per cent., and I think there is still room for further improvement. Until medical officers of health succeed in extinguishing that very motile organism the typhoid bacillus it is our duty as practitioners to use every possible precaution to prevent our patients from becoming either directly or indirectly a cause of disease in others. In every case we should try to find out the source of infection so that the patient may not be further subjected to any deleterious influence and that others may not be exposed to the risk which he has failed to escape. Milk is not an infrequent medium of carrying the typhoid bacilli, and some time ago 32 children in the Liverpool district contracted typhoid fever on the same day from partaking of ice-cream from an Italian vendor of that article. At that time Dr. Charles A. Hill found some samples of ice-cream to contain a greater number and variety of micro-organisms than were to be found in Liverpool sewage. The oyster scare, which was well founded, had an excellent effect in improving the conditions under which these bivalves are reared, but even now many oysters, shrimps, &c., are not above suspicion. Flies have been credited with the spread of disease, and it is easy to see how they might readily contaminate meat and other articles of diet by conveying the bacilli from fæces or other filth. The house drainage should receive immediate attention, and all suspected articles of food or drink should be well boiled.

To prevent any spread of disease from the patient all the excretions and soiled clothing should be thoroughly disinfected; the difficulty is not so much in finding a good and cheap disinfectant as in inducing nurses to use it in efficient quantities. About half a pint of the disinfectant should be placed in the bed-pan and afterwards another half-pint should be poured over the fæces, and the whole should be well mixed and allowed to stand for two hours before being poured down the closet or otherwise disposed of. The urine and sputum should also be disinfected. The soiled linen should be soaked for two days in a solution of perchloride of mercury or biniodide of mercury (1 in 1000) before being washed. After the recovery or the death of the patient all the bedding and wearing apparel should be

[1] The Treatment of Typhoid Fever, 1892.

disinfected by heat. The nurses should be instructed to keep bed-pans and other utensils scrupulously clean and to avoid all splashing when removing the dejecta. Nurses should keep their finger-nails short, and they should thoroughly wash their hands in a solution of biniodide of mercury (1 in 1000) after every time they attend upon a typhoid fever patient and more especially before they handle any article of food. A person could carry a sufficient number of bacilli under a finger-nail to infect many people. We should all remember that many micro-organisms are really very difficult to kill. I recently found in the urine of a patient suffering from cystitis a very motile bacillus which closely resembled the bacillus of typhoid fever, and it was exceedingly lively in urine containing 40 per cent. of strong hydrochloric acid. Professor Wright and Major Semple, R.A.M.C., have introduced a typhoid vaccine as a preventive against this disease, but its value is not yet clearly defined.

### GENERAL MANAGEMENT.

The patient should be put to bed and kept there until convalescence is well established. He must be taught to use the bed-pan and urinal from the commencement. His posture should be occasionally changed. He should be kept quiet, fed at regular intervals, and encouraged to sleep. The nurses should be kind, bright, and cheerful; they should have a noiseless tread and be well versed in their duties; and they should keep an accurate record of all matters appertaining to the case. The room should be large, airy, well ventilated, and kept at a temperature of from 60° to 65° F., preferably by an open fire. I like to see the windows somewhat open both day and night. It is no doubt difficult in cold weather to maintain a uniform temperature with open windows, but ventilation must never be sacrificed for heat. The relatives should be taught that fever patients do not catch cold. It is often difficult to instil this doctrine even into medical men. Often when I have exposed a fever patient for examination I have seen the medical attendant almost shivering with fear lest his patient should catch a chill. The bronchitis and congestion of the lungs from which typhoid fever patients frequently suffer are due to the typho-toxin and not to any chill, but still it is not well to increase the mischief by making the patient breathe cold air. Cylinders of oxygen have not yet been introduced in the treatment of this disease, and I hope we may long escape such a delusion and snare; what the patient requires is the pure air of heaven. The late Sir B. W. Richardson showed that prebreathed or devitalised oxygen did not support life, but in the stuffy rooms in which many fever patients are treated they can get little else, and in such cases a little oxygen from a cylinder is a poor substitute for a breath of fresh air. The room should also be well lighted, and a certain amount of carpeting on the floor as a means of lessening noise is decidedly useful. The bedstead should, if possible, be narrow and be approachable from either side. It should be fitted with spring and hair mattresses, and the latter should be protected by waterproof sheeting. Flock- and feather-beds, eider-down quilts, and other non-conductors of heat should be strictly interdicted. During the continuance of the fever it is much better that the patient should have no nightshirt. He should lie between linen sheets and should only have an additional counterpane, or at most a single blanket and light quilt. As a rule, I keep the blanket and quilt over the lower extremities and only cover the body with a sheet. There are, of course, many serious cases in which with a high internal temperature the extremities are very cold, where the covering has to be considerably modified, and it may be even necessary to apply hot bottles to the limbs and wrap them in flannel. All the clothing should be kept scrupulously clean. In many thin and emaciated patients it may be advisable to use a water-bed to prevent bed-sores, but it should never be used as an antipyretic agent. It is usually, however, only requisite at a late stage of the disease when an antipyretic effect is not needed. When the patient's temperature approaches the normal the risks from chills begin, and of course the covering should then be increased.

In severe cases the patient is dull, apathetic, and stupid; his intellectual faculties are blunted; and he is, perhaps, delirious and oblivious to all external impressions, so that he makes no demand and does not care to do anything for himself. The nurse, therefore, should be well trained and on the alert. She should keep his nose scrupulously clean, as dry, offensive secretions quickly accumulate and rhinitis is readily established with consequent risk of secondary infection. These secretions do not annoy the patient and he makes no attempt to remove them. An excellent method of keeping the nose clean is by frequently spraying it with a 2 per cent. solution of menthol in paroleine, or liquid vaseline. All dried secretions can be readily removed by a little cotton-wool on a probe. The mouth, also, should be kept very clean and all sordes should be removed from the lips and teeth. An excellent cleaning agent for spraying out the mouth consists of equal parts of glycerine and peroxide of hydrogen. Equal parts of tincture of iodine and glycerine painted along the gums is a good antiseptic. Sponging the hands and face and the application of a little eau de cologne to the head are grateful to the patient.

### DIET.

Milk is almost universally held to be the staple diet in typhoid fever. It is looked upon as a model food because it contains all the ingredients necessary for repairing waste and supplying heat, but it does not necessarily follow that because the constituents are in the proper proportions for a growing infant it is best suited for a fever patient where the conditions are completely reversed. In the latter the anabolic processes are in abeyance, and the katabolic processes are exceedingly active. Where milk is the only diet in fever cases the tissue waste is exceedingly great. The nitrogenous element of food may be readily supplied by milk, but the sugar and fat are not in sufficient quantity in that fluid and they require to be supplemented from other sources. Moreover, as Sir William Jenner pointed out, a pint of milk is often more difficult to digest than a mutton-chop, and whatever foods we order we should see that they are properly digested. The stools should therefore be carefully inspected, and when any curd of milk or other undigested food is present the diet should be peptonised. The milk should be invariably diluted with an equal quantity of plain water, barley-water, or whey. I also recommend the addition of sugar of milk and chloride of sodium—the latter is too frequently omitted from febrile diets. Dr. Burney Yeo recommends the addition of an alkaline tabloid composed of bicarbonate of soda, bicarbonate of potash, carbonate of magnesium, and common salt, but I have arrived at the conclusion that all alkalies are positively injurious in typhoid fever. Latterly I have been trying buttermilk, which, as you all know, contains a large quantity of lactic acid, as I found that the typhoid bacilli did not multiply so rapidly in it as in new milk. However, they do multiply and become very active in buttermilk, and I have not yet found a diet inimical to their growth. When buttermilk is used it should be well diluted, otherwise the curds will appear in the stools. A patient in a recent severe case did remarkably well on buttermilk, with cold compresses on the abdomen and three injections of anti-typhoid serum. From two to three pints of milk are sufficient in the 24 hours, though the total quantity of fluid drunk by an adult should be at least five or six pints. When there is much intestinal decomposition with flatulent distension I am very fond of ordering whey prepared by boiling equal quantities of buttermilk and new milk and straining. To each pint of whey one or two ounces of cream may be added.

The best diet to prevent the wasting in typhoid fever has not yet been determined. The loss of weight during the febrile process is to a considerable extent due to the dehydration of the tissues, but the water is afterwards quickly replaced and this to a great extent accounts for the rapid increase of weight which usually takes place when the convalescent stage is reached. During the fever there is little or no tissue upbuilding and therefore the demand for nitrogenous food cannot be great, but if the pyrexia, which is inevitable, is not to be maintained at the expense of the tissue we must supply an abundance of other fuel in the form of easily assimilable carbohydrates or hydrocarbons. The great objection to carbohydrates is their undoubted liability to undergo fermentative changes with the liberation of gas in the intestinal tract. No doubt when the salivary and pancreatic secretions are much diminished ordinary farinaceous diet should not be given until it has been subjected to the amylolytic action of some of the many ferments in the market. If you keep the patient's temperature down by hydrotherapeutic measures you will find that the whole of the digestive processes are much improved. Of this class of diet I frequently order peptonised bread and milk, Benger's food, Mellin's food, or Horlick's malted milk, and about two ounces of butter, or five or six ounces of cream daily. During the febrile stage the food, whatever it be, should be liquid and should be administered every two or

three hours when the patient is awake. If there be constipation or not much diarrhœa extract of malt will be found useful, and sugar or sugar of milk may usually be given, also the expressed juice of ripe grapes, but neither the skins nor seeds. If any stimulating effect is required beef-tea, mutton broth, or chicken broth, with vegetable juices but no cellulose, clear soup, beef essence, cocoa, and coffee may be given, and one or two raw eggs may be administered daily during any stage of the disease. The patient should be encouraged to drink plenty of pure cold water, toast-water, barley-water, whey, or home-made lemonade. If there be any constipation a little cream of tartar may be added to the lemonade.

During the whole course of the fever do not rest satisfied with the report that the bowels are freely opened but daily inspect the abdomen, examine the urine, and, if convenient, see one of the stools. If the bowels be at all loaded, if the abdomen be distended, and if the urine contain an appreciable amount of indican you have sufficient evidence that decomposition of the contents of the bowel is going on, consequently the bowels should be cleared out with a dose of castor-oil or other gentle laxative, and the diet should be diminished.

The liquid nourishment should be continued until the temperature has been normal for a week or ten days and then you should begin cautiously with fish, chicken, mutton, lightly-boiled eggs, sweetbreads, boiled tripe, &c. When the patient has been fairly nourished during the fever his temperature is not likely to be affected when he begins to take solid food unless there be constipation, and this should not be allowed to occur. Recrudescences and relapses are often ascribed to the use of solid food when the occurrences are merely coincidences. Constipation with retention of the typhoid and colon bacilli is a more likely source of future mischief.

### ALCOHOL.

The most severe case of typhoid fever can be better treated without alcohol than with it, and the conditions demanding its use in this disease are very few and far between. Alcohol is not a food in the proper acceptation of the word: it is a sedative, or, to use a commoner though less accurate designation, a stimulant. It causes vaso-motor paresis which is usually sufficiently accomplished by the fever poison without any assistance. This effect may be necessary during the chilly stage, during collapse, or to counteract the effect of a cold bath, but in a well-managed case, without any heroic treatment, such influence should not often be necessary. In cases where there is high body temperature with cold extremities I occasionally allow a pint of good bitter beer in the 24 hours as a diffusible stimulant to lessen peripheral resistance to the circulation. When there is obstinate vomiting a little champagne occasionally does good and in cases of sudden collapse a few teaspoonfuls of brandy may be given. By writers on this subject most elaborate rules have been laid down to guide the administration of alcohol according to the state of the heart, the pulse, the tongue, and the nervous system, but these rules are usually utterly devoid of any physiological basis, and even their authors would have great difficulty in determining beforehand their proper application in practice. Alcohol is not a cardiac tonic, but it is usually prescribed in typhoid fever with that object in view, and we frequently see drugs having a diametrically opposite action—such as alcohol on the one hand and strychnine or digitalis on the other—given with the view of strengthening the heart's action and tiding the patient over a difficulty. I have seen the limbs jumping about under the influence of alcohol and strychnine given with the view of supporting that common bugbear, a weak heart, when there was not the slightest probability of any cardiac failure. We frequently hear of patients being "kept alive" for a certain number of days on brandy; but as these cases generally end in death it would perhaps be more accurate to say that the only nutriment they had during the last few days of life was diluted brandy. The tenure of life held under such conditions is usually dearly bought. I have never been able to see why dying patients should have their mouths parched with brandy, often of an abominable quality, which would early make them cry out, if they were only able, for a drop of cold water to moisten the tongue. Some men prescribe alcohol freely in typhoid fever and pneumonia because they believe in its efficacy; others because they are too weak to run counter to the views of the patient's relatives; and teetotalers, who have no personal knowledge of alcohol, because it is the popular thing to do and they do not like to be considered prejudiced. They have a vague idea that what they consider a potent poison in health must be a powerful remedy in disease. Many of those who prescribe it very sparingly think that it should be specially given to patients accustomed to it in health so as not to disturb any long-acquired habit, but in my experience—and I am supported by the experience of Sir William Broadbent—these are just the cases which do better with other medicaments. Frequently I prescribe some alcohol for myself and my healthy friends, but when any of them are diseased I am not likely to poison them with this drug. If I were convalescing from typhoid fever I would enjoy some good port, and I do not care to prohibit others from what I would probably take myself. As a food or antipyretic agent it is of very little value and should be avoided during the febrile stage unless there be some special reasons for its use. The large quantities of alcohol which are frequently prescribed must inevitably lead to cardiac asthenia and so protract convalescence. It is not a cardiac tonic and should be reserved for a time when its potency in lessening peripheral resistance and so relieving the heart will be of service.

### ANTIPYRETIC TREATMENT.

The fever induced by the typho-toxin is a natural part of the disease and so long as it remains moderate in degree it does not demand much interference. There are some severe cases where the intensity of the poison stupefies the nervous system and subdues the temperature, so that the case only assumes a normal course when the bowels have been well cleared out and we get febrile reaction. We know that high temperature can work mischief irrespectively of the agent which induced it, though it is a mistake to suppose that all the evils of fevers are due to the high temperature, because apyrexia might be maintained throughout the whole course of the illness by the use of powerful antipyretic drugs without modifying the course of the disease or improving the patient's chance of recovery. The albuminous degeneration which occurs in the striped muscular fibre of the heart and voluntary muscles, in the cells of all the glandular organs, and even in the nerve cells, is no doubt largely due to the high temperature, though I think the fever poison must also be partly credited with this degradation, because evidence of its existence can be found in all severe cases no matter how well the temperature has been subdued. The temperature, however, is the one factor in fever which can be most readily combated, and when this has been efficiently carried out by the antipyretic action of water the signs of degeneration are correspondingly lessened. For example, in my tank cases[2] the heart's action improved and there was no anxiety as to cardiac paralysis. The functions of the glandular organs were restored, and although the nervous irritability was heightened there were no signs of nervous exhaustion and consequently convalescence progressed rapidly. I have discarded the use of drugs as antipyretic agents, and I shall now consider some of the methods of applying water for the reduction of the temperature.

*Warm or tepid bath.*—At the very commencement of an attack of fever, before we know the exact nature of the illness with which we have got to deal, when the patient is chilly and restless, I think the cleansing and soothing effects of a warm or tepid bath will be decidedly beneficial. Cold sponging is very grateful to the patient, but it has no lasting effect on the temperature and is only suitable for mild cases.

*Cold compresses.*—Cold compresses kept constantly applied over the whole abdomen form the antipyretic agent which I most frequently employ, the patient having no nightdress or other body-covering except a large compress sufficient to cover the abdomen and lower ribs. This is wrung out of cold or iced water and frequently changed, except when the patient is asleep; even then it can be changed without much disturbance, but so long as it is moist it acts as a cooling agent and frequent renewal is not necessary. A large cradle is placed over the patient and this is covered with a single sheet, so that evaporation is allowed to take place freely. In order to keep the four extremities comfortable I direct a large stocking to be kept on each, or they may be wrapped in flannel. In the case of the lower extremities it is often advisable to keep a warm bottle in the bed.

*The hammock.*—In very severe cases I have used the continuous bath, and latterly I have been adopting a somewhat more convenient method of having the patient swung in a hammock and a small constant stream of tepid water kept

[2] The Treatment of Typhoid Fever, 1892.

playing over the abdomen. This is best carried out by taking the framework of an Ilkley couch and stretching over it loose canvas cloth such as is used for sunblinds in greenhouses; this hammock can be set on any ordinary bedstead. A water-pillow is placed to receive the patient's buttocks, but otherwise he can be placed naked on the canvas. A large piece of flannel is now used as a wet compress to cover the abdomen and lower part of the chest. A small, constant stream of water at 80° F. diffuses over this flannel, passes on to the hammock, and gravitates to the most dependent part near the buttocks, where it is easily collected in a large bucket or other receptacle. If it be thought necessary to increase the comfort of the patient a large spirit lamp can be kept constantly burning under the bed; this increases the evaporation and so carries away a great amount of latent heat. The patient's thighs and legs should be kept wrapped up in a dry blanket. This method so far has been successful in each case in which I have tried it. One of my best cases was a severe attack of typhoid fever in a delicate woman who was in the sixth month of pregnancy; she was also suffering from advanced mitral stenosis and congestion of the lungs, and towards the end of the third week she had a severe attack of intestinal hæmorrhage. She made a good recovery, carried the child to the full time and on many occasions since has shown herself and child at the Liverpool Royal Infirmary. Any man with a little ingenuity can easily devise a method to suit the circumstances of any individual case. An ice-bag to the right iliac fossa in cases of intestinal hæmorrhage is very useful, but even in these cases I prefer its use to be intermittent as the constant application is apt to lower the vitality of the parts. Where there is a tendency to pulmonary œdema, one of the most fatal complications of this or any other disease, it indicates failure of the right side of the heart, and in such cases I like cold compresses to the abdomen to lower the temperature, rouse up the nervous energy, and increase the depth of the respirations.

*Cold-water enemata.*—It is an excellent plan to allow a pint and a half of cold water containing some antiseptic, such as permanganate of potassium or peroxide of hydrogen, to gravitate up the large bowel once or twice daily. This helps to cool the body, but, what is of much more importance, it washes away all decomposing matter which has accumulated in the large bowel; this should be adopted in every case where there is an excess of indican in the urine. These methods of treatment keep the temperature within bounds, improve the vaso-motor tone, and raise the systemic blood-pressure and increase the depth of the respirations. There is marked improvement in the digestive tract; the tongue becomes moist and clean, the salivary secretion increases, the appetite and digestion improve, the diarrhœa disappears, and the character of the motions changes for the better. There is, as a rule, no delirium and the general well-being of the patient greatly improves. Although the diet is, in my opinion, always liberal, there is usually a craving for more to eat long before it is deemed advisable to give solid food.

## MEDICINE.

I have not much faith in trusting too much to physic in typhoid fever, though I usually adopt a routine plan of giving some intestinal antiseptic, not with the view of killing the bacilli, but to prevent intestinal decomposition. If the patient comes early under observation and there is much retching or vomiting I am sufficiently old-fashioned to order an emetic, and of all emetics the simplest is the best. I prefer two or three tumblerfuls of hot water to anything else. If these symptoms occur at a later stage of the disease they are indicative of prostration with congestion of the stomach or perhaps some cerebral affection and should be treated accordingly, but no emetics should be administered. If the cause be referable to the stomach a sinapism should be applied to the epigastrium, and a few small doses of calomel, and perhaps a little champagne, be given. When the vomiting is due to typhoid ulcers in the stomach, which I have seen in two cases, it is a most difficult matter to control. I always begin treatment with a good calomel purge and afterwards keep the bowels well opened during the whole illness.

Constipation in this disease is frequently due to an inactive and distended condition of the large bowel, of which the natural secretion is defective and consequently the liquid portion of the fæces is absorbed. The hard scybala may cause irritation and set up a catarrhal flux which, however, is usually insufficient to effect their removal; the frequent small liquid motions may give rise to the impression that the trouble is diarrhœa rather than constipation. To empty the large bowel and lessen its torpidity enemata given daily or every other day will prove highly efficacious. I saw a patient recently who had been dosed with lead and opium pills until the abdomen was as tense as a drum. The tympanitic distension was relieved and real constipation established by repeated cold-water enemata containing permanganate of potassium.

The more or less routine administration of intestinal antiseptics has a good effect in preventing decomposition and lessening distension, but you must not suppose that you are thus going to kill the typhoid bacilli. I generally use benzo-naphthol or salol, but no doubt many other antiseptics are equally useful. The chlorine mixture of Dr. Burney Yeo has, perhaps, the advantage of neutralising his alkaline tablets. You can more effectually disinfect the fæces outside than inside the intestinal tract. Frontal headache and sleeplessness in the early stage are best relieved by Dover's powder and salicylic acid; these remedies are also useful in tympanitis. For bronchial catarrh and hypostatic congestion of the lungs use ammonium carbonate and caffeine. Pulmonary œdema, indicative of right cardiac failure, is best relieved by cardiac tonics and agents to increase the action of the respiratory pump, such as caffeine, strychnine, digitalis, cold applications to the abdomen, &c. Pneumonia and pleurisy are usually supposed to demand stimulants, but the stimulant should be more especially ammonia, or ammonia, caffeine, and quinine, but not alcohol. In pneumonia and hypostatic congestion of the lungs there is vaso-motor paresis which requires to be counteracted by a vaso-motor tonic and not intensified by alcohol.

## HÆMORRHAGE.

A sudden fall of temperature, a blanched anxious face, and a small weak pulse should direct our attention to the occurrence of hæmorrhage, even before the blood has appeared in the stools. No doubt epistaxis, and even hæmorrhage from the bowels, at an early stage of the fever from congestion of the mucous membranes, is not a matter of much importance, but profuse hæmorrhage about the end of the third week is a fact of the gravest significance. The patient is not then in a position to bear the loss of blood, and the sudden fall of blood-pressure places his life in imminent danger. The horizontal position should be strictly maintained, and if the loss of blood has been great the foot of the bed should be raised so as to depress the patient's head below the rest of his body. All unnecessary disturbance of the body should be avoided, and the urine should be drawn off with a catheter. The first internal remedy should be a dose of opium. A teaspoonful of laudanum is a fair dose for an adult, and it is much better to give one large dose than several small ones. The best hæmostatic is perhaps turpentine in 10-minim doses every hour or two. In these cases there is generally defective arterial tone, to counteract which ergotin may be injected hypodermically, or chloride of calcium may be added to the turpentine mixture. Suprarenal capsule is a good vaso-constrictor, but its value in intestinal hæmorrhage is somewhat problematical. If there be any vomiting the patient should have ice to suck or swallow. Until all hæmorrhage has ceased the stomach should not be troubled with much food, and this should only consist of beef essence, soup, peptonised gruel, and whey. The intermittent use of a large ice-bag, especially if there be any febrile temperature, to the right iliac region is efficacious.

## PERFORATION.

Early surgical operation, though hitherto not very successful, offers perhaps the best chance of recovery. If the operation be not performed early there is apt to be general peritonitis, which further militates against the patient's recovery. Moreover, the coils of bowel get glued together, and it may be difficult to find the perforation. Some time ago I saw a case with Mr. W. R. Judd in which we diagnosed perforation on account of the collapse, abdominal distension, and complete absence of hepatic and splenic dulness. From the history we concluded that the perforation occurred soon after Mr. Judd's visit on the previous day, and at least 24 hours before the night on which I saw the patient. We thought him too ill for operation, but agreed that Mr. F. T. Paul should see him with us early on the following morning. We put him on a starvation diet, and ordered

10 grains of Dover's powder and 10 grains of salicylic acid every four hours. In the morning when we three met he seemed better; his pulse was fuller and less frequent, and the tympanites was less. The question of operation was postponed for 24 hours, and we directed that the starvation and powders should be continued. On the following morning he was much better; the tympanites was less, and the hepatic and splenic dulness could be made out. The question of operation was dismissed and he eventually made a good recovery. In this case, I presume, the perforation was soon sealed up by glueing to a neighbouring coil of bowel, but such a happy result is of rare occurrence.

### PERITONITIS.

When this follows on perforation the treatment will be similar to that of the condition which induced it. When it occurs as a rare complication of typhoid fever without any antecedent perforation, it should be treated on general principles. In these cases it is usually due to indiscreet attempts to check the diarrhœa, and is perhaps not so frequently caused even in these typhoid cases by the bacillus typhosus as by the bacillus coli communis and other micro-organisms. The intestinal congestion should be diminished by small and repeated doses of calomel and opium, and if there be constipation or only slight diarrhœa small doses of some saline, such as sulphate of soda, should be given as frequently as is requisite. The pain should be completely subdued by opium. The circulation in the abdomen and the distension of the bowel should be lessened by an ice-bag or cold compresses applied to the abdomen.

### CYSTITIS.

Cystitis is not of infrequent occurrence and may be due to either the typhoid or colon bacillus. The best remedies are urotropine and salol.

### TYMPANITES.

There is always, or nearly always, a certain amount of flatulent distension of the abdomen in typhoid fever, but excessive tympanites usually occurs when there is great nervous prostration and should be treated accordingly. It is not infrequently due to over-feeding and consequent intestinal decomposition. When, therefore, you find much abdominal distension and excessive indican in the urine the diet should be materially diminished. Cold compresses to the abdomen do good; intestinal antisepsis should be carried out to lessen fœtor and prevent decomposition of the contents of the bowel. For this purpose such remedies as salicylic acid, salol, benzo-naphthol, turpentine, menthol, cajuput, ammonia, quinine and caffeine, &c., will be found useful. The food should be peptonised.

### CONSTIPATION.

Sir William Jenner pointed out that this condition when persistent is frequently associated with deep ulceration and a greater liability to hæmorrhage. It should be counteracted by mild laxatives, such as calomel, salines, or castor-oil, and any over-loading of the large bowel should be removed by enemata. I never see a case where the diarrhœa is such as to require astringents. The possibility of retention of urine, too, should always be kept in mind.

### ALBUMINURIA.

This is a valuable indication as showing the state of the circulation. It indicates renal congestion and is associated with defective cardiac energy, diminished vis viva in the circulation, and vaso-motor paresis. Such conditions are improved by hydro-therapy, and vaso-motor tonics such as caffeine, digitalis, ammonia, and quinine.

### PROTRACTED INTERMITTENT PYREXIA.

Typhoid fever is often protracted by recrudescences and relapses, but occasionally we get evening rises of temperature lasting for one or more weeks due to secondary infections. I have seen the pyrexia in some such cases cut short by a few injections of antistreptococcic serum.

### THROMBOSIS AND EMBOLISM.

In both these conditions the part affected should be kept warm and at perfect rest. Ammonia should be freely administered, and frequently opium is of good service. I shall not weary you further with the treatment of rare complications nor with that of convalescence. If you follow the lines which I have laid down you will have a low mortality, and that is a point of primary importance to your patients.

# EXPERIMENTAL PROOF OF THE MOSQUITO-MALARIA THEORY.

BY PATRICK MANSON, C.M.G., M.D., LL.D. ABERD., F.R.C.P. LOND., F.R.S.,
MEDICAL ADVISER TO THE COLONIAL OFFICE; LECTURER, LONDON SCHOOL OF TROPICAL MEDICINE, ETC.

ALTHOUGH the theory that the malaria parasite is transmitted from man to man by particular species of mosquito is now accepted by all biologists and medical men who have given adequate attention to the subject it cannot be said that the general public (including those Europeans who in malarious countries might benefit by the practical application of the theory) unreservedly believe in it, much less practically apply it. Endless objections the outcome of an imperfect acquaintance with the subject—and perhaps of a disinclination to admit that a pathological puzzle of so many centuries' standing could receive so simple an explanation—have been raised by the amateur biologist and sanitarian; so much so that it seemed not improbable that a great principle, pregnant with important issues, might remain barren and unutilised.

Impressed with this fear and being anxious to see some fruit from a theory which I knew to be true and for which I was in a measure responsible, I cast about for means by which the conversion and coöperation of the public might be secured. I felt that unless the public believed in the efficiency of the sanitary measures so definitely indicated by the mosquito-malaria theory and to some extent understood the principles on which these measures should be founded they would not adopt them or, what is so necessary to the success of all such measures, coöperate heartily in carrying them out. As the histological, biological, and experimental evidence which had satisfied men of science was not understood by the public it seemed to me that some simple demonstration was required such as would be unanswerable and at the same time readily comprehended by laymen.

Grassi, in conjunction with Bignami, had succeeded in conveying malaria by mosquito bite. Although these experimenters took every care to exclude fallacy the fact that the experiments were made in Rome—itself of fever repute and in the middle of a highly malarial district—had an undoubted influence in preventing due appreciation by the public of the conclusive nature of their work. Furthermore, things occurring at a distance and in a strange land do not appeal so strongly as do things happening in our midst. It occurred to me, therefore, that if I repeated Grassi and Bignami's experiments in a more dramatic and crucial manner—that if I fed laboratory-reared mosquitoes on a malarial patient in a distant country and subsequently carried the mosquitoes to the centre of London, and there set them to bite some healthy individual free from any suspicion of being malarial, and if this individual within a short period of being bitten developed malarial fever and showed in his blood the characteristic parasite—the conclusion that malaria is conveyed by the mosquito would be evident to every understanding and could not possibly be evaded. It also occurred to me that if a certain number of Europeans who had never suffered from malaria kept in good health and free from malaria during an entire malarial season in an intensely malarial locality where all inhabitants and visitors suffered from malaria, and if they kept well without the use of quinine or other medicinal prophylactic, simply by avoiding mosquito-bite, that the above conclusion would be accentuated; and, also, that if this immunity were attained by inexpensive means, means which did not interfere seriously with comfort, pleasure, or business, the mosquito-malaria theory would not only be proved to the satisfaction of the public but the public would be willing to accept the sanitary measures which the theory and experiments indicated. After having obtained promise of support from the Colonial Office and from the London School of Tropical Medicine and securing volunteers for the experiments, still further to accentuate my object and to arrest the attention of those principally interested I publicly announced in a popular lecture at the Colonial Institute that the above experiments were about to be undertaken and with the same object in view I ventured to forecast their issue.

### EXPERIMENT I.

Dr. Bignami and Dr. Bastianelli very kindly undertook to send me relays of infected mosquitoes from Rome. I have to thank these gentlemen for the great care exercised in this somewhat responsible matter. Every case of malaria coming to a general hospital is not suitable for experiment. To have sent mosquitoes infected with malignant tertian parasites might have endangered the life of the subject of the experiment; and quartan-infected insects might have conferred a type of disease which, though not endangering life, is extremely difficult to eradicate. The cases, therefore, on which the experimental insects were fed had to be examples of pure benign tertian—a type of case not readily met with in Rome during the height of the malarial season—and the absolute purity of the infection could be ascertained only by repeated and careful microscopic examination of the blood of the patients.

When the insects had fed, Dr. L. Sambon, who had gone to Rome in connexion with Experiment No. II., placed them in small cylindrical cages made of mosquito netting stretched on a wire frame. Four such cylinders were packed in a well-ventilated box and forwarded to the London School of Tropical Medicine through the British Embassy in Rome. By the courtesy of the Postmaster-General they came forward by the Indian mail so that they arrived in London some 48 hours after leaving Rome. A good many of the mosquitoes died on the journey or soon after arrival; but a fair proportion survived and appeared to be healthy and vigorous. We are indebted to Dr. Sambon for the method employed of caging mosquitoes. Future experimenters will find it very useful. To infect the insect, or to become infected by them, the experimenter has merely to place his hand in the cage after carefully untying the netting at one end or, better, by laying the closed cage on his damped hand.

The following notes regarding this experiment are by Mr. P. Thurburn Manson, Guy's Hospital:—

"I am 23 years of age. I was born in China, but have lived in this country since I was three years old, and have never been abroad since, nor in any district in this country reputed to be malarial. I am healthy.

"The first consignment of mosquitoes arrived at the London School of Tropical Medicine on July 5 h. Only some half-dozen had survived the journey. They were in a languid condition and would not feed satisfactorily. One may have bitten me. By July 7th they were all dead. The second consignment arrived on August 29th. They had been infected in Rome on August 17th, 20th, and 23rd by being fed upon a patient with a double benign tertian infection. The patient was reported to have had numerous parasites, including many gametes, in his blood. On arrival 12 insects were lively and healthy-looking. I fed five of them on August 29th, three on August 31st, one on Sept. 2nd, and one on Sept. 4th. They bit my fingers and hands readily. The bites were followed by a considerable amount of irritation which persisted for two days. The third consignment arrived on Sept. 10th. They had been fed in Rome on Sept. 6th and 7th on a patient suffering from a simple tertian infection but with very few parasites in his blood. There were some 50 to 60 mosquitoes in good condition. 25 bit me on Sept. 10th and 10 on the 12th.

"Up till *Sept. 13th* I had been perfectly well. On the morning of the 13th I rose feeling languid and out of sorts with a temperature of 99° F. By midday I was feeling chilly and inclined to yawn. At 4.30 P.M. I went to bed with severe headache, a sensation of chilliness, lassitude, pains in the back and bones, and a temperature of 101·4°. Repeated examinations failed to discover any malarial parasites in my blood.

"*September 14th.*—I slept fairly well but woke at 3 A.M. with slight sweating and a temperature of 101°. During the day my temperature ranged between 101° and 102°. The symptoms of the 13th were exaggerated and anorexia was complete. Several examinations of the blood were made again with negative result. To relieve headache 10 grains of phenacetin were given at 6 P.M.; I perspired profusely but slept indifferently.

"*September 15th.*—I woke at 7 A.M., feeling distinctly better, with a temperature of 100·4°. No malaria parasites were discovered on repeated examinations of my blood by my father. About 2 P.M. I commenced to feel slightly chilly; this soon wore off and I became hot and restless. By 4.30 P.M. my temperature was 103·6°. It remained about 103° till 9 P.M., when profuse sweating set in. I am told there was some delirium.

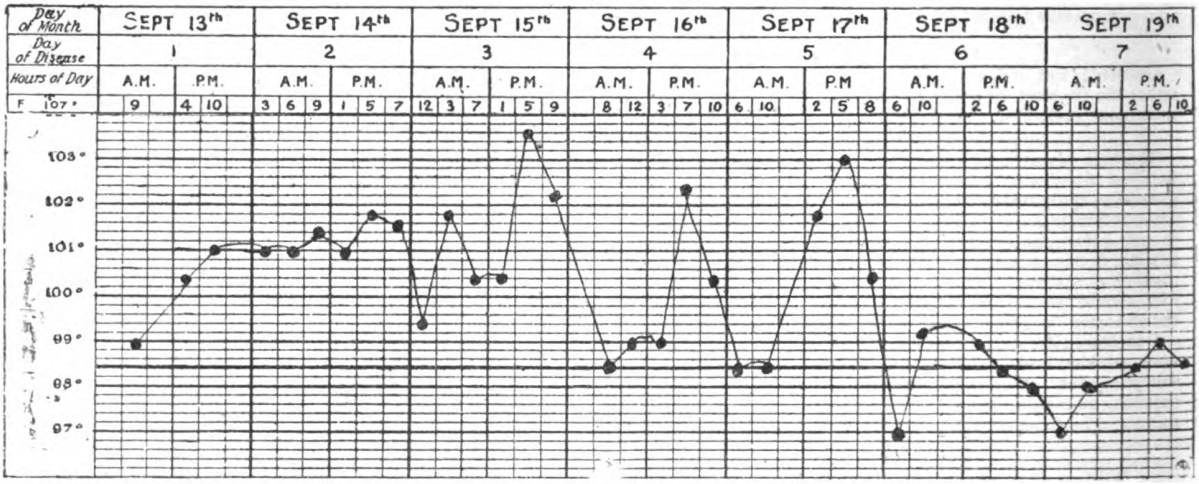

Chart showing course of temperature in the case of Mr. P. Thurburn Manson.

"*September 16th.*—I woke at 8 A.M. feeling quite well; my temperature was 98·4°. I made several blood examinations and found one doubtful half-grown tertian parasite. In the afternoon and evening there was a recurrence of fever (temperature 102·8°) relieved by sweating.

"*September 17th.*—I again felt quite well on waking after a good night's sleep; my temperature was 99°. At 10 A.M. several half-grown parasites, a gamete, and two pigmented leucocytes were discovered in the first blood film examined. During the day many tertian parasites were found. Their presence was verified by my father and by Dr. Frederick Taylor, Lieutenant-Colonel Oswald Baker, I.M.S., Dr. Galloway, Mr. Watson Cheyne, F.R.S., and Mr. James Cantlie, some of whom saw the films prepared. About 2 P.M. the sensation of chilliness returned (temperature 101·8°). By 5 P.M. the temperature had reached 103°. There was then copious sweating. The edge of the spleen could be felt on deep inspiration and there was a slight feeling of discomfort in the region of that organ. Dr. Frederick Taylor and Mr. Watson Cheyne confirmed the presence of splenic enlargement. By 9 P.M. the temperature had fallen to 99·2° and I was feeling better. Quinine (10 grains) was taken.

"*September 18th.*—I woke after a good night feeling perfectly well (temperature 97°). 10 grains of quinine were taken and subsequently five grains every eight hours. I continued perfectly well all day. A few three-quarter-grown tertian parasites and some gametes were found during the forenoon and afternoon; they were seen by Dr. Oswald

Browne, by my father, and by myself. At 10 P.M. the parasites had disappeared, the last being found at 5 P.M.

"*September 19th.*—No parasites were discovered. The temperature is normal. I am feeling quite well. There is no splenic enlargement and no tenderness. Appetite has returned.

"*September 25th.*—In good health. No recurrence of malarial symptoms."

EXPERIMENT II.

A wooden hut, constructed in England, was shipped to Italy and erected in the Roman Campagna at a spot ascertained by Dr. L. Sambon, after careful inquiry, to be intensely malarial, where the permanent inhabitants all suffer from malarial cachexia, and where the field labourers who come from healthy parts of Italy to reap the harvest after a short time all contract fever. This fever-haunted spot is in the King of Italy's hunting ground near Ostia, at the mouth of the Tiber. It is water-logged and jungly and teems with insect life.

The only protection against mosquito bite and fever employed by the experimenters was mosquito netting-wire screens in doors and windows and, by way of extra precaution, mosquito nets around their beds. Not a grain of quinine was taken. Dr. Sambon and Dr. G. C. Low, Signor Terzi, and their two Italian servants entered on residence in their hut early in July. They go about the country quite freely—always, of course, with an eye on anopheles—during the day, but are careful to be indoors from sunset to sunrise. Up to Sept. 21st, the date of Dr. Sambon's last letter to me, the experimenters and their servants had enjoyed perfect health, in marked contrast to their neighbours who were, all of them, either ill with fever or had suffered malarial attacks.

For the present I content myself with announcing this result. Complete details of their experiences will doubtless be made public by Dr. Sambon and Dr. Low at the termination of the malarial season and of their experiment at the end of October. Suffice it to say that these gentlemen express themselves as satisfied that protection from mosquito bite protects from malaria and that protection from mosquito bite is perfectly compatible with active outdoor occupation during the day.

It remains for the public to apply the lesson taught by these experiments. Will this be done? Already I have heard objections and difficulties mooted. I saw it advanced recently that it is impossible to avoid mosquito-bite in the tropics and that it was useless to try to do so. One has sometimes to go out in the evening; a medical man, for example, must visit his patient at any hour. This is quite true; but, surely, because we cannot escape a risk altogether this is no reason why we should not try to minimise it. Dr. C. W. Daniels, who has recently returned from British Central Africa, tells me that not one mosquito in a thousand in that country carries malarial zygotes—that is to say, is infective. If a man exposes himself, therefore, in British Central Africa to mosquito-bite habitually, so that he gets bitten, say, ten times every night, the chances are that he is effectually inoculated with malaria some four times a year; but if the same man systematically protected himself from mosquito-bite and, in consequence of his care, reduced the chances of being bitten to once a month he may be 100 years in British Central Africa before he gets infected. This minimising of risk is certainly worth striving for.

The question of expense cannot for a moment be entertained in discussing the means for protection. One life saved, one invaliding obviated, would, even in a pecuniary sense, pay for all the wire gauze and mosquito-netting requisite to protect every European house in West Africa.

These experiments, together with the work of Ross, Grassi, Celli, Bignami, Bastianelli, and other Italians, and the recent observations on native malaria by Koch and the representatives of the Malaria Commission of the Royal Society and Colonial Office, plainly indicate that the practical solution of the malaria problem lies (1) in avoiding the neighbourhood of native houses, the perennial source of malaria parasites; (2) in the destruction, so far as practicable, of the breeding pools of anopheles; and principally (3) in protection from mosquito-bite.

Queen Anne-street, W.

# PUERPERAL SEPSIS[1]

BY R. P. RANKEN LYLE, M.D. DUB.,
LECTURER ON MIDWIFERY AND DISEASES OF WOMEN AND CHILDREN, UNIVERSITY OF DURHAM COLLEGE OF MEDICINE; EX-ASSISTANT MASTER, ROTUNDA HOSPITAL, DUBLIN.

PUERPERAL sepsis is nothing more or less than a surgical fever arising from the infection of a wound, the only differences being—(1) the large extent of surface liable to infection; (2) the structures involved; (3) the presence of a quantity of dead material which easily lends itself to infection; and (4) the fact that the patient is undergoing certain physiological changes, this, perhaps, making her more liable to infection. The different varieties of puerperal sepsis are as follows: (1) sapræmia, or septic intoxication due to a local cause; (2) septicæmia, or acute septic infection or acute sepsis; and (3) pyæmia. We shall consider these three conditions separately.

## I.—SAPRÆMIA.

Sapræmia is a fever due to the absorption of the products of decomposition from the parturient canal or due to the absorption of toxins produced by micro-organisms in the structures surrounding the parturient canal. It may be divided into different varieties according to the cause: (1) fœtid sapræmia; (2) suppurative sapræmia; and (3) inflammatory sapræmia.

1. *Fœtid sapræmia.*—This is due to the absorption of the products of decomposition in the parturient canal, and the materials which may decompose are the lochia, blood-clot, retained pieces of membrane, or portions of placenta. The symptoms of this variety are: first, a headache which often precedes the initial rise of temperature and pulse, which, as a rule, occurs on the third or fourth day succeeding the confinement but may occur later, and which is usually proportional to the quantity of decomposing material. The lochia of course are abundant and fœtid; the pulse, which is full and bounding, varies from 110 to 120, and the temperature varies from 101° to 103° F. The tongue at first is clean, but in a day or so it becomes heavily coated. The patient sleeps very well and has no pain, and on the second day of the fever the headache usually disappears. In severe cases the symptoms may be ushered in with a rigor, and if the case be allowed to continue without treatment the symptoms become aggravated and the patient's complexion becomes sallow. The milk function is not interfered with and perspiration is usually excessive. The treatment of this condition consists in efficient douching with creolin solution (half an ounce to one gallon of warm water) until the temperature falls to normal. If a vaginal douche be not sufficient to reduce the temperature and the rate of the pulse it should be followed the day after by a uterine douche, and in severe cases this should be administered twice daily. The diet should be generous and easily digestible. In cases, however, where in spite of douching the symptoms do not abate, and where there is reason to believe that some of the membranes or part of the placenta have been retained, a gentle curetting with Rheinstädter's flushing curette will be of service.

2. *Suppurative sapræmia.*—This is a sapræmia due to the absorption of toxins produced by suppuration on the surface of the parturient canal. It includes puerperal ulcer, either on the perineum, the vaginal wall, or on the cervix, suppurative colpitis, and septic endometritis. This condition is usually more sudden and severe than fœtid sapræmia, being generally ushered in with a rigor, with high temperature (from 103° to 105°) and very rapid pulse (from 120 to 150). There is no pain and the lochia are septic but not so abundant or foul-smelling as in cases of fœtid sapræmia. This condition may commence any day during the puerperium after the second, either independently of, or as a consequence of, fœtid sapræmia. The pulse and temperature continue high, and in cases where a small extent of surface is involved and is properly treated the temperature quickly falls to normal, usually by crisis; in other cases—especially in those of considerable septic ulceration of the vagina—the temperature may remain high for some days in spite of treatment, and then suddenly falls to normal by crisis. The tongue is heavily coated. The patient sleeps fairly well, takes her

[1] An introductory communication to the Northumberland and Durham Medical Society on March 8th, 1900.

food well, but generally feels ill. A puerperal ulcer may appear on the perineum, on the vaginal wall, or on the cervix, and always in the situation of a laceration. This ulcer is irregular in outline and its surface is of a dirty greyish appearance and secretes a small amount of highly septic pus. It can be easily seen by separating the vulva and looking at the perineum or examining the cervix by means of a speculum. The treatment consists in washing it three times daily with creolin or corrosive sublimate solution, dusting it with iodoform, and keeping a piece of iodoform gauze applied to it. The ulceration may, however, extend to the whole vaginal wall, causing the pulse and temperature to rise very high—the temperature from 104° to 106° and the pulse from 140 to 160. The treatment which answers best in this condition is similar to the last-mentioned—viz., douching twice daily with creolin solution and packing the vagina loosely with iodoform gauze. Stimulants are usually indicated (small doses at frequent intervals) and concentrated and liberal diet. Septic endometritis is the most fatal form of sapræmia. Its symptoms are much the same as those of a severe case of fœtid sapræmia and its treatment is somewhat similar. The question of curetting in this condition is still subject to discussion. Some authorities maintain that it is best to curette in order to remove the diseased endometrium, while others consider that, no matter how carefully it is performed, curetting will only remove part of the diseased endometrium, leaving a large raw surface for further infection, and the protective layer which is formed under the diseased endometrium is also removed,[2] predisposing to the spread of the septic processes into the connective tissue of the uterus itself and thereby causing a septic metritis or perhaps even acute sepsis. The method, however, recommended by Dührssen of douching and plugging the uterine cavity with iodoform gauze has met with the greatest success. Extirpation of the uterus has also been advocated by some authorities, but in the performance of this operation we are confronted with three grave dangers. The first is the condition of the patient herself prior to the operation, the second is the danger of infecting the patient during the operation, and the third is the impossibility of ascertaining whether the septic condition is limited to the endometrium or has extended into the surrounding structures. The results attained will perhaps teach us not to advise this operation. As a consequence of septic endometritis, salpingitis or puerperal pyosalpinx may supervene. This comes under the head of gynæcology.

3. *Inflammatory sapræmia.*—This is due to an acute inflammation of the vagina, uterus, or parametrium. This condition is invariably associated with considerable pain. In simple colpitis the vagina is red, hot, and tender, with pain on micturition and defecation, but the lochia need not necessarily be fœtid. Douching with weak creolin solution will give considerable relief. The bowels should be kept freely open. In cases of metritis there is considerable pain on palpating the uterus which is enlarged and the lochia are red and abundant. The treatment, besides occasional douching of the uterus, is chiefly symptomatic. Parametritis is an inflammation of the cellular tissue surrounding the uterus and of that between the layers of the broad ligaments. It is usually a consequence of metritis or of sepsis extending through a cervical laceration. The pain is referred to either iliac fossa, and a tender swelling can be felt bimanually on either side of the uterus. The patient may lie with either one or both legs drawn up, indicating that the inflammation has extended to the cellular tissue of the iliac fossa. It is often associated with pelvic peritonitis. The treatment consists in perfect rest, aperients, good, concentrated, easily digestible diet, syrup of the iodide of iron, or small doses of iodide of potassium internally, and tampons of cotton wool, permeated with glycerine and ichthyol (10 per cent.), placed daily in the vaginal fornix. Parametritis usually ends in resolution, but may break down into abscess.

## II.—SEPTICÆMIA.

Puerperal septicæmia, otherwise known as acute sepsis or acute septic infection, is an extremely fatal condition, but fortunately comparatively rare. It may arise independently or as a consequence of any of the preceding conditions. Its chief symptoms are an initial rigor occurring from 36 to 60 hours after the date of infection, with an extremely rapid pulse (from 140 to 160), which is weak and compressible; the temperature is irregular; in some cases it remains normal and in others it may rise to 106° or higher. Vomiting, sometimes uncontrollable, is a common symptom, and the patient has little or no desire for food. She is sleepless and restless and throws her arms about, and although she has an extremely anxious and pinched expression on her countenance yet she says "she feels quite well." This condition is known as "euphoria." The milk is absent or it rapidly disappears from her breasts, and the lochia are scanty or absent. The patient gets rapidly worse, the pulse disappearing altogether at the wrist and the conjunctivæ turning yellow shortly before death. The pathology of this condition is that septic micro-organisms get directly into the blood through the lymphatics, where they multiply by myriads, and the severity of the poison is so great that the sensorium is incapable of receiving impressions of pain and the patient feels and says she is quite well. In cases of septicæmia which are not consequent on septic conditions in or around the parturient canal death is so rapid that pathological conditions have not time to develop. Besides local treatment, such as douching and plugging the uterus with iodoform gauze, large doses of alcohol have been recommended with strychnine and digitalis, but no treatment has as yet been proved to be of any avail. The patient dies in from two to five days.

I dare say that the members of this society would consider me guilty of a grave omission if I did not mention something about what was supposed to be a panacea for this condition—viz., antistreptococcic serum. Well, I have never seen a true case of puerperal septicæmia treated successfully with this serum, neither have I ever read of one. I have seen, however, several cases of different forms of sapræmia treated with it without any beneficial result whatsoever, either transitory or permanent. I have also read a few reports of cases of different forms of puerperal sapræmia which were, in my opinion, wrongly diagnosed as puerperal septicæmia and treated by it with alleged good results which I believe were merely coincidences. In some of these cases great importance was attached to the fall of the temperature and the pulse which usually followed the injection of the serum. This might possibly have been due to the profuse diaphoresis caused by the serum and not to any beneficial result of the serum on the patient. I remember treating a patient about the beginning of 1899 who was very ill from puerperal sepsis. On a certain Sunday morning her condition was extremely grave and I decided to inject some antistreptococcic serum. I was, however, unable to obtain it until the following day, but I am happy to say that this patient anticipated me by having a normal temperature the following morning. Had I been fortunate enough to have had the serum at hand and to have used it that Sunday I might possibly have attributed her improved condition on the following morning to the use of the serum, and this case might possibly have figured in the annals of medical literature.

Now it appears to me, from the very small number of supposed successful cases reported and considering that the antistreptococcic serum is being and has been used very extensively throughout the British Islands and by the ablest obstetricians, that the good results claimed for it have not been sustained. I am also inclined to believe that these reported successes have been merely coincidences and especially so as these cases were apparently cases of sapræmia and not puerperal septicæmia as reported. I went into the shop of a well-known local druggist recently and asked if he kept any antistreptococcic serum. He said that he used to keep a quantity of it but that he did not keep it now as it was never asked for. From this fact, I suppose, puerperal septicæmia has entirely disappeared from this whole district.

## III.—PYÆMIA.

Pyæmia is due to the absorption of a septic thrombus in one of the uterine sinuses into the blood-stream by means of the veins. It may spread by continuity of the veins or septic emboli may form and be carried and lodged in any part of the body, causing localised purulent inflammations or abscesses. The symptoms may develop up to the twenty-first day following the confinement, or perhaps later, by a rigor which is usually followed by a succession of rigors. Its symptoms, sequelæ, and treatment are similar to those of surgical pyæmia.

Now, speaking generally, it is well to remember that any obstetrical operation—even the making of a vaginal examination—is similar to a surgical operation and the sources of infection are exactly similar. You will find it stated in Lusk's "Science and Art of Midwifery," which is one of

[2] Lusk: Science and Art of Midwifery, p. 666, Plate IV.

the very best of modern obstetrical text-books, that "the ordinary carriers of infection are unquestionably the unclean hands, instruments, utensils, clothing, wash material, and the like, which are brought in contact during or after labour with the genitals of the female." Now, this is perfectly true if we have a healthy patient to deal with, but I believe it is quite possible for an unhealthy patient to infect herself. By unhealthy I mean a patient suffering from a gonorrhœal vaginitis or other form of septic vaginitis, or a patient who has suffered on a previous occasion from some septic condition of the internal genitals.

I have not said much about the bacteriology of puerperal sepsis because this matter is at present undergoing investigation and definite conclusions have not yet been formed, and I do not think that until they are formed we can say anything definite as to the use or value of antistreptococcic serum. It is, I believe, possible to grow cultures of streptococci from some samples of this serum, and besides, by injecting a patient with a quantity of this serum it is quite possible to produce a condition known as antistreptococcic neuritis—a condition which has been observed not only in this country but also on the continent and which, if it occurred, would materially prolong the puerperium.

Now there are a few rules which, I think, if they were strictly observed would materially lessen the prevalence of puerperal sepsis.

1. The thorough disinfection of the patient's external genitals and the hands and forearms of the medical attendant and the nurse, prior even to a vaginal examination. It is very easy to understand how, when a vaginal examination is made with fingers which have not been thoroughly washed and disinfected, material may be carried into the vagina which will be rubbed off the fingers and remain there. This material may in some instances be washed away by the liquor amnii, but in a certain proportion of cases it will remain there and cause decomposition of the lochia or perhaps it may get into some of the fissures of the vaginal wall consequent on parturition and either set up acute inflammation or perhaps cause acute sepsis itself.

2. The abolition of routine ante-partum and post-partum douching. The three principal solutions used for this purpose are corrosive sublimate, creolin, and carbolic acid. Corrosive sublimate solution has no advantages over creolin solution and has several decided disadvantages. If it is used for ante-partum douching, besides washing away Nature's antiseptic lubricant[3] (the vaginal mucous secretion), owing to its astringent properties it hardens and corrugates the vaginal mucous membrane, predisposing to extensive fissuring of the vaginal wall and a large laceration of the perineum during parturition, thereby considerably increasing the danger of septic infection. When used post-partum it does not act as an antiseptic because the mercury unites with the albuminous constituents with which it comes in contact, forming an insoluble albuminate of mercury, which is inert. This remains adherent to the surface of the parturient canal, being absorbed into the system later, and causes severe diarrhœa or diarrhœa with melæna (symptoms of corrosive sublimate poisoning). Besides, by hardening the surface of the parturient canal it prevents the natural secretions from taking place, predisposing to subinvolution of the uterus and consequent metritis and endometritis. Creolin and carbolic acid solutions (half an ounce to one gallon) are quite free from these disadvantages. In giving a uterine douche it is not a question of the amount of harm you can do to the bacteria inside the uterus, as this must necessarily be associated with serious injury to the patient. It is more a question of washing away the bacteria out of the uterus, without at the same time doing further injury to the patient, consequently it is the quantity and not the quality of the douche which is important. Routine ante-partum and post-partum douchings are not only unnecessary but are often dangerous.

3. All instruments used during an obstetric operation should be aseptic and when not in use should be kept in aseptic cases.

4. The proper conduct of the third stage of labour. This means, briefly, conducting the third stage with the patient on her back, the obstetrician's hand on the fundus, and waiting until the placenta comes naturally into the vagina before expressing it. If the placenta does not come naturally into the vagina within half an hour massage may be used to the fundus and gentle expression. In case the membranes get caught the placenta should be lifted gently and the membranes twisted so as to secure their coming away entire. The placenta and membranes should be now examined and if any large piece of either be retained steps should be taken to remove it. The uterus should be well contracted before the binder is applied.

5. The strict limitation of vaginal examinations. In an ordinary case where there is no unusual delay one vaginal examination is sufficient, made after the rupture of the membranes to ascertain if there is a prolapse of the cord. Any further information, especially as regards the position of the fœtus, can be more easily and more accurately obtained by means of abdominal palpation.

6. The disuse of all so-called "aseptic lubricants." The use of lubricants is only a means of carrying infection into the parturient canal and preventing the infection from being washed away by the liquor amnii. Lubricants are absolutely unnecessary, just as they are unnecessary in performing an abdominal section except where the patient has sores on the vulva or vaginal wall, in which case a practitioner should use them for his own safety. The commonest so-called aseptic lubricant is carbolised vaseline. It has been proved to be a good culture medium for bacteria, the vaseline protecting the micro-organisms from the action of the carbolic acid. I once saw a large puerperal ulcer which I believe was directly due to the use of this lubricant.

7. The immediate suturing of all perineal lacerations, not only for the sake of the patient's comfort in after life, but also to diminish the extent of surface liable to infection.

Newcastle-on-Tyne.

[3] The Bacteria of the Vagina and their Practical Significance, by J Whitridge Williams, American Journal of Obstetrics, October, 1898.

## THE ETIOLOGY OF SCARLET FEVER.

BY WILLIAM J. CLASS, M.D.,
MEDICAL INSPECTOR, CHICAGO HEALTH DEPARTMENT.

IN the *Berliner Klinische Wochenschrift* of July 2nd and 9th there appeared an article by Adolph Baginsky and Paul Sommerfeld in which they announce the discovery of a micro-organism whose constant presence in the throat secretions and blood of patients suffering from scarlet fever causes them to believe that it is probably the causative factor of this disease. It is this article that has inspired me to a further communication, as well as a desire to present to the medical profession the evidence that has so far accumulated favouring the view that the diplococcus scarlatinæ, the germ discovered by me, is the cause of scarlet fever. The only notice taken by Baginsky and Sommerfeld of my investigations into the cause of scarlet fever is the statement that I had found a diplococcus resembling a very large gonococcus, which organism was considered by me as being the cause of scarlet fever. As the source on which this statement was based they mentioned a leading article on the subject which appeared in THE LANCET of Nov. 18th, 1899 (p. 1385). This article dealt with a preliminary report made on the subject under consideration. I mention this fact, not because I feel in the least hurt by receiving such scant consideration at the hands of Baginsky and Sommerfeld, but for the reason that if they had taken the trouble to read some of the later contributions by myself and others on the diplococcus scarlatinæ they would not have failed to notice the similarity in many particulars of this germ with the one whose discovery they announce. I do not presume to state positively that these two germs are identical—in fact, this would be almost impossible without having seen their cultures; but I will take the liberty to compare certain parts of the description of their organism with those made of the diplococcus scarlatinæ. The reader may then judge for himself whether there is any similarity or not. In order not to be accused of any inaccuracies or twisting of terms I shall give Baginsky and Sommerfeld's statements in German exactly as they appeared in their article. Before beginning this comparison, however, I will say a few words in regard to the term "streptococcus."

In recent medical literature it is quite common to find an organism described as a streptococcus when a culture shows short chains of three or four cocci mixed with single cocci. I have even seen an organism described as a streptococcus where an examination showed perhaps one or two short chains in a microscopical field filled with single cocci. It

appears to me that the term "streptococcus" should be reserved for an organism the cultures of which show the chain form predominating, the chains being well defined and not simply an accidental arrangement of three or four cocci of perhaps different size and shape. In ordinary life one would hardly call three pieces of iron, each of different size, when joined together a chain. This statement is made because we are about to deal with an organism that has been described as a streptococcus but which does not seem to conform with the proper conception of the term "chain coccus."

Baginsky and Sommerfeld describe the morphology of their germ as follows: "In direkten aus Blut in den Organen entnommenen Trockenpräparat erkennt man zu 2-3 gelagerte runde Keime, also Diplokokken oder kürzeste Ketten, hie und da auch wohl als Tetraden gelagert."[1]

In an article published by me[2] I made the following statement in regard to the diplococcus scarlatinæ under the heading "Morphology": "In young cultures grown from the blood of a scarlet-fever patient the germ is usually seen as a diplococcus, both segments of which are globular. Streptococcus forms are occasionally, though rarely, met with, as are also single cocci." "Tetrads are frequently seen and probably denote the beginning division of the organism." It would be very peculiar if two observers who have each examined over 300 cases of the same disease should find two entirely different germs whose morphology at the same time bore such close resemblance. So much for the primary blood examinations. As we continue our comparison certain discrepancies apparently appear. I shall again quote from the article by Baginsky and Sommerfeld: "Die Morphologie der so dargestellten Mikroben ist folgende; von wechselnder Länge; in solchen von 3-4 Individuen, indess auch in langen geschlängelten Ketten bis zu 50 Gliedern und darüber. Der Keim des Streptococcus ist meist kreisrund, zuweilen allerdings auch abgeplatten und zwar in der Richtung senkrecht zur Kette, so dass zwei mit den breiten Seiten aneinander liegen. Studiert man einzelne Glieder der Ketten genauer in gefärbten Präparaten so erkennt man vielfach Diplokokkenformen, indess nicht immer, andere erscheinen als kleinere oder grössere runde Körner. Die Form war, wie man erkennt, äusserst wechselnd und wandelte sich je nach den Medien, in welchen die Cultur weiter poussirt wurde. In direktem Präparat als Diplokokken aufgetretene oder als kurze Kettchen erscheinende Formen wuchsen in alkalischer Peptonbouillon zu langen Ketten, die z. Th. bei der Umzüchtung auf Agar und bei der Thierpassage sich wieder in kurze Ketten von 3—6 Gliedern umwandeln lassen. Hierbei variirte auch die Grösse des einzelnen Keimes aus demselben ursprünglichen Stamm in mannigfachster Weise."[3] In the article referred to[4] I made the following statement in regard to the morphology of the diplococcus scarlatinæ: "A diplococcus polymorphous in character, but resembling as ordinarily seen in slides made from fresh cultures grown on *my medium* (earth agar), a very large gonococcus. This biscuit-shaped appearance is best seen in specimens that have been but lightly stained. Tetrads are frequently seen, and probably they denote the beginning division of the organism. In very old cultures grown under favourable conditions it shows as an enormous coccus having a slight cupped appearance, the dividing line between the two portions being very indistinct in the more deeply stained specimens. By the division of the large diplococcus a number of smaller organisms are formed which group together and do not appear as diplococci during the very early stages of their growth." This description of the organism was made from cultures grown on earth agar, while that of Baginsky and Sommerfeld showing long chains was made from cultures grown in alkaline peptone bouillon (vide ante). It is of importance to remember this fact, as the morphology of the germ varies according to the medium in which it is grown. ("Die Form war, wie man erkennt, äusserst wechselnd und wandelte sich je nach den Medien, in welchen die Cultur weiter poussirt wurde.") It is this great variability in form when grown on other media than earth agar which caused me to think—as I mentioned in the article in the *New York Record*—during my early experience that the growth upon plain agar, &c., was a contamination. Jaques[5] who studied cultures of the diplococcus scarlatinæ grown on the ordinary media says in regard to its morphology: "This germ has a wide morphology. Sometimes one stage and then another will become accentuated according to the environment and nutrition. Sometimes conditions are favourable to its growth in chains and the culture will show streptococcus form. In another case it will grow as a staphylococcus and still in another as a diplococcus." This variability of form which characterises my germ, as well as that which Baginsky and Sommerfeld claim as a new discovery, is further shown by the description of the diplococcus scarlatinæ by Gradwohl,[6] who states that it shows no permanence of morphologic character, as well as by the following statement made by me in an article[7] on the subject: "This germ varies greatly in size and shape, and although the form usually seen in primary cultures grown on the earth agar is the diplococcus resembling a very large gonococcus, still a primary culture may show it in one of its other forms. In order to prove the identity of the organism it becomes necessary to make successive transplantations of the culture from one tube to another, allowing it to grow for a few days at the least before transferring to a fresh tube. The different forms can be best studied by beginning with a culture of the large diplococcus; by transferring a loop of this culture to another tube of earth agar and allowing it to grow for a few days and then making an examination of the growth it will be found to consist largely of tetrads; by the still further division of the tetrads in the next subculture small diplococci are formed, and through the division of these single cocci," &c. Another point of semblance between these two findings is the variability in virulence which both germs seem to possess in common.

Baginsky and Sommerfeld state: "Bei allen Thieren war die Virulenz eine äusserst variable"[8]; and again, "Die Virulenz der Kokken ist nicht nachhaltig und geht leicht verloren, verminderte sich zumeist schon erheblich nach wenigen Tagen."[9] This is a fact to which I have repeatedly called attention when speaking of the diplococcus scarlatinæ. I will not attempt to draw any comparison from the biologic characters of the two germs, as the following statement by Baginsky and Sommerfeld excludes such a course: "In unseren eigenen Culturen waren wir vergeblich bemüht gewisse Eigenheiten des Wachsthums in den einzelnen Stämmen zu fixiren; immer wieder variirte ebensowohl der einzelne Keim der Ketten in Form und Grösse, wie auch die Virulenz und selbst das biologische Verhalten in den Nährmedien, so dass wir die Differenzirung einzelner Formen schliesslich aufzugeben gezwungen waren."[10] In looking over the comparison made in the preceding remarks I think the reader cannot fail to be impressed with the fact that in all probability the germ found by Baginsky and Sommerfeld in their primary examinations was identical with the diplococcus scarlatinæ, as the description given of it by them and my description of the germ as seen in primary cultures have almost the same wording. Of course, a point of difference is that Sommerfeld and Baginsky, in the description of the growth of their germ on agar, &c., speak of it as a streptococcus, while this term cannot be applied to the diplococcus scarlatinæ as ordinarily seen. However this may be, the germ found by Baginsky and Sommerfeld in their primary blood examinations was certainly not a streptococcus but a

[1] "In a dry preparation taken directly from the blood in the organ micrococci are seen arranged in groups of two or three—that is to say, diplococci or very short chains; here and there also tetrads appear."—ED. L.

[2] New York Medical Record, Sept. 2nd, 1899.

[3] "The morphology of the microbes is as follows: of variable length; generally consisting of three or four units, but sometimes arranged in long twisted chains. The nucleus of the streptococcus is usually circular but sometimes flattened, and lying in a direction perpendicular to the chain, so that two lie with their broad sides together. On observing individual cocci more closely in stained preparations numerous diplococci are seen, which occasionally contain larger or smaller circular nuclei. As will be seen, the form was very diverse and varied according to the medium in which the culture was grown. In fresh preparations containing diplococci or short chains these microbes when inoculated in alkaline pepton-bouillon grow in long chains, which can partly be again changed to short chains when transferred to agar or passed through animals. At the same time the size of the individual cocci, though derived from the same source, vary greatly."—ED. L.

[4] New York Medical Record, Sept. 2nd, 1899.

[5] The Journal, May 26th, 1900, p. 1299.

[6] Philadelphia Medical Journal, March 24th, 1900, p. 682.

[7] New York Medical Record, Oct. 7th, 1899, p. 33.

[8] "In all animals the virulence was extremely variable."—ED. L.

[9] "The virulence of the cocci is not lasting and is easily lost; it is considerably lessened after a few days."—ED. L.

[10] "In our own cultures we endeavoured in vain to establish certain characters of the growth in separate generations; but again the individual units of the chain always varied in form and size as well as in virulence and even in the biological behaviour in the nutrient media, so that finally we were compelled to abandon the differentiation of individual forms."—ED. L.

diplococcus. As they themselves say: "Zu zwei bis drei gelagerte runde Keime, also Diplokokken oder kürzeste Ketten." If a germ which shows such an arrangement is a streptococcus, why, then, every known coccus is a streptococcus. In their further description they speak of chains containing 50 or more cocci being found in the bouillon cultures. Such lengthy chains my diplococcus scarlatinæ never forms, and from an experience based on the examination of hundreds of cases of scarlet fever I feel justified in stating that a long streptococcus, an organism to which the name streptococcus can be properly applied, cannot be found in cultures made from the blood of an uncomplicated case of this disease. If it is present it is a sign either that the case is not an uncomplicated one or that the culture is contaminated. The impression made upon me by the reading of Baginsky and Sommerfeld's paper was that they had in their culture the diplococcus scarlatinæ mixed in some instances with a long streptococcus the presence of which was accidental. Streptococci are present in the pharyngeal mucus of a certain proportion of cases of scarlet fever, but not by any means invariably, nor do they ever compose the bulk of the culture. So much for the present in regard to the discovery of Baginsky and Sommerfeld. Let us now consider the evidence in favour of the view that the diplococcus scarlatinæ is the cause of scarlet fever.

1. *Evidence showing that the diplococcus scarlatinæ is a germ not heretofore described.*—In March, 1899, at a meeting of the Chicago Medical Society, I presented a preliminary report, together with a demonstration of specimens of a germ whose constant presence in a series of about 30 typical cases of scarlet fever had led me to believe that it was probably the cause of this disease. This germ, when grown upon a medium especially devised by me, showed certain peculiarities in its morphology—very large gonococcus form—and growth whereby it could be distinguished from other germs. A very careful and exhaustive search in bacteriological literature made prior to this announcement had failed to show the description of any germ resembling the one described by me. Since this preliminary report was published I and others have further elaborated the matter without finding anything conflicting with it. It is true that the large gonococcus form is not a constant feature of this organism, nor did I ever claim this to be the case; but it is the usual form seen when grown on the earth agar and one which serves to distinguish it from other organisms. This form, if not present in the primary cultures, can always be obtained by successive transplantations on the earth agar.[11] A full description of the different forms of this organism appears in the June issue of *Medicine* and in the *New York Medical Record*, Sept. 2nd, 1899. Numerous findings of diplococci and streptococci in scarlet fever had been recorded before I announced my discovery, and may give rise to the view that I presented nothing new. While it is possible that some of these discoverers really had the diplococcus scarlatinæ in their cultures they at best only described one of its forms, and none prove the constant presence or the relationship of the germ to the disease. Neither did they reproduce the disease or show any way by which the germ could be distinguished from others. Thus Crajkowski[12] in 1895 announced that he found diplococci in the blood of 16 cases of scarlet fever; this organism presented nothing characteristic, nor did Crajkowski follow up his examination as far as can be seen by searching the literature on the subject. That the diplococcus scarlatinæ is a *new* germ is further shown in an article by Gradwohl,[13] who gives a very good description of its biological characters.

2. *Evidence showing that the diplococcus scarlatinæ is constantly present in scarlet fever.*—The presence of this germ in cases of the disease has been well proved. Thus Gradwohl[14] found it in seven consecutive cases and Jaques[15] demonstrated its presence in every one of a large number of cases examined. I myself announced before the Chicago Pediatric Society in December, 1899,[16] that I had found it in 300 successive cases of scarlet fever and scarlatinous sore-throat. Page[17] of Boston announced that he had found a germ corresponding to the description of the diplococcus scarlatinæ in a number of cases. Besides these published findings I have personal knowledge of its having been found in the blood, throat secretions, and scales of scarlet fever patients by a number of other competent observers whose results have not as yet been published. These results have been so uniform that I am absolutely certain of my ability to demonstrate the presence of the diplococcus scarlatinæ in the blood, throat secretions, and scales of every typical case of scarlet fever given me for examination.

3. *Evidence showing that the diplococcus scarlatinæ is a pathogenic micro-organism.*—This germ is pathogenic for mice, swine, and guinea-pigs. Mice are most susceptible, and a small quantity of a virulent culture injected subcutaneously will sometimes kill the animal in an hour's time. As a rule, death takes place within 12 hours of the time of inoculation. Swine, as a rule, show no reaction from the subcutaneous injection unless a very large quantity of a virulent culture is used. Swine are known to be insusceptible to the influence of most pathogenic germs when injected subcutaneously. Even the bacillus of hog cholera produces but little effect when administered in this manner; therefore it is not surprising that the diplococcus scarlatinæ is not very pathogenic when injected subcutaneously. Intra-abdominal injections give rise to grave symptoms, and if a sufficient amount of a virulent culture is used it will cause the death of the animal. The usual method which I have used in order to produce typical symptoms of scarlet fever in swine has been to inject a culture grown on agar and mixed with sterilised water directly into the circulation. For this purpose either the ear veins or the femoral veins were used. The amount of culture used for these experiments varied according to its virulency; usually, however, one cubic centimetre was sufficient, and in some instances caused the death of the animal a few days subsequent to its injection. Guinea-pigs usually succumb to the intra-abdominal injection of 0·1 cubic centimetre of a virulent culture. During the first few days after inoculation these animals usually showed but little signs of sickness; then they began to refuse food, gradually became more and more emaciated, and death occurred as a rule from 10 to 14 days after the injection was made. Subcutaneous injections generally were without result. These observations have to a great extent been verified by the experiments of Gradwohl.[18] Rabbits and white rats appear to be but slightly, if at all, susceptible, while cats and dogs are immune. The diplococcus could, as a rule, be easily obtained from the organs of the susceptible animals after death and from their blood during life. Cultures taken from the blood of the ventricles and from the spleen generally showed a pure growth.

4. *Evidence showing that scarlet fever can be reproduced in animals by the diplococcus scarlatinæ.*—The diplococcus scarlatinæ is the first germ that has ever been discovered through whose agency a disease has repeatedly been produced, which has been recognised by competent men as being apparently identical with scarlet fever as it appears in human beings, so far as the rash and scaling are concerned. The animals used to reproduce the disease were white swine. When such an animal receives an intravenous injection of a virulent culture of the diplococcus scarlatinæ it will usually sicken within a few hours, there will be a rise in temperature, the animal will become restive and refuse food; after three or four days, as a rule, a decided reddening of the skin will appear, which lasts from one to two days, to be followed within a week to two weeks by profuse scaling. Sometimes the eruption is more of a papular character and the reddening not well marked, but usually it can be easily demonstrated, especially if the colour of the animal is compared with that of one in good health. The disease has been reproduced by the writer in a considerable number of swine, the number being large enough to exclude the possibility that it was merely an accidental phenomenon. These results have been further verified by Gradwohl[19] and Jaques.[20]

5. *Evidence showing that the pathologic changes in the organs caused by the diplococcus scarlatinæ resemble those of scarlet fever.*—As an example of the gross changes produced by the diplococcus scarlatinæ I will give a brief statement of the findings in a young pig which was inoculated in the pathological laboratory of Rush College on Feb. 17th, 1900. About one cubic centimetre of agar culture was rubbed up with five cubic centimetres of sterilised water and injected into the femoral vein. On the 24th the animal was found dead and on post-mortem examination the following changes

were found: "Spleen is enlarged and congested; Malpighian bodies stand out prominently. Kidneys show cortex pale in colour, with a few small hæmorrhages near surface; capsule comes off easily; pelvis of kidney is congested and drips blood on section; pyramids stand out plainly. Liver shows numerous whitish necrotic areas and is congested; blood drips on cutting. Lymphatic glands of neck are enlarged, varying in size from a Lima bean to that of a hickory nut. Slight amount of effusion appears between layers of pericardium. Walls of intestine are congested and show numerous hæmorrhagic spots. Other organs are apparently normal." The mice and guinea-pigs that were examined post mortem also usually showed gross signs of nephritis. In regard to their other organs nothing positive could be stated on a macroscopical examination. The organs of a considerable number of animals were preserved for microscopical examination the results of which will be reported later. Gradwohl has confirmed the occurrence of nephritis in swine and guinea-pigs after inoculation with the diplococcus scarlatinæ.

6. *Evidence showing that the disease produced through the agency of the diplococcus scarlatinæ is of a contagious nature.*—There are a number of facts on record which go to prove that this germ produces a contagious disease. Thus, Jaques[21] stated that when a healthy pig was placed with two pigs that were scaling after having been inoculated with the diplococcus it developed a rise in temperature lasting several days, followed by scaling, thus showing that it had evidently contracted the disease by contact. Gradwohl, in an article previously quoted, states that if a healthy mouse be put in a cage in which another mouse that has been inoculated with the diplococcus scarlatinæ has been kept the healthy mouse will sicken and die and will show the diplococcus scarlatinæ in its organs post mortem. I have seen similar results occur a number of times while carrying on my own experiments, and I think that it must be admitted that the contagious nature of the disease produced is extremely suggestive and speaks strongly in favour of the claim that the diplococcus scarlatinæ is the causative factor of scarlet fever.

7. *Influence on blood of scarlet fever patients on the activity of the germ.*—Under this heading I will quote a few experiments described in a paper[22] by me, to wit: "A loop of pure culture of the diplococcus was diluted with 15 minims of distilled water. One-half of this was poured over a plate of glucose-agar; to the other half were added 10 drops of blood from a patient who had just recovered from an attack of scarlatina, and this mixture was poured over a similar plate. Both were put into an incubator, the temperature of which was kept at about 36° C. At the end of 24 hours the plates were removed. The plate made from the culture without the addition of the blood showed innumerable minute colonies of the diplococcus, while on that to which the blood had been added there were only a very few colonies. Presumably these had grown, because from the tendency to clump some of them had not been exposed to the action of the blood. This experiment was repeated five times with almost identical results. Each time there was a slight growth of the culture to which the blood had been added, but the growth was so much more profuse in the one without this addition that the inhibitory action of the scarlet fever blood on the growth of the germ could be plainly demonstrated. Blood from a child five months old where the possibility of a prior infection with the germ could safely be excluded produced no inhibitory action. The other experiment consisted in inoculating four ordinary grey mice, each of which received five minims of a solution of a virulent culture of the diplococcus scarlatinæ in distilled water. Two of the mice had previously received by subcutaneous injection five minims each of blood serum taken from a patient recently recovered from scarlet fever. The two animals that had not received the blood inoculations died within 18 hours, while of the two that had been injected with the blood one lived about 40 and the other 72 hours." These experiments have since been repeated a number of times with practically the same result. In making the first set of experiments quoted it was also necessary to use a virulent culture, as one that has been grown a long time on artificial media is not so sensitive.

8. *Finding of the diplococcus scarlatinæ in throat secretions of patients with scarlatinous sore-throat, a further proof of its specific character.*—In an article on the etiology of acute tonsillitis[23] I made the following statement regarding the diplococcus scarlatinæ: "It is not only invariably present in the angina of scarlet fever, but during an epidemic of this disease it will frequently give rise to an acute tonsillitis without any eruption, although not infrequently these cases are followed by a nephritis and sometimes by desquamation. It may sound like a bold statement to make, nevertheless I am fully convinced that a person who has had an attack of acute tonsillitis due to the diplococcus scarlatinæ is rendered immune against scarlet fever, or, in other words, that this form of angina is nothing more or less than scarlet fever without the presence of an eruption." And, further, "the contagion from a case of scarlatinous sore-throat is capable of giving rise to typical scarlet fever in another person who has been exposed to it." The occurrence of scarlatina sine eruptione is something that has for a number of years been accepted, more or less generally, but it could not be proved positively, as the causative germ of scarlet fever was not known. Admitting for the present that the diplococcus scarlatinæ is the cause of scarlet fever it will be found that during an epidemic of this disease cases of scarlatina sine eruptione are of far greater frequency than has generally been supposed to be the case. Your sceptic may cry out that the finding of the diplococcus scarlatinæ in so many cases of apparently simple sore-throat speaks strongly against its being a specific micro-organism. On the contrary, it is just this fact which goes a long way to prove its specific nature. If it was only present in typical cases of scarlet fever how could we explain those cases in which one child in a family has scarlet fever while several others at the same time develop only a tonsillitis, followed perhaps by nephritis and desquamation? The contagion must necessarily be the same, for frequently these cases of angina give rise to an attack of typical scarlet fever in another member of the family. Furthermore, if these cases of angina were not scarlatina sine eruptione, how could we account for the fact that so many people escape scarlet fever? The finding of the diplococcus shows that they had in the majority of instances been rendered immune by an attack of angina caused by this germ and that the eruption of scarlet fever is simply one manifestation of the activity of this micro-organism. The presence of an eruption is not absolutely necessary to make a diagnosis of scarlet fever, however inconsistent this may seem when the name of the malady is considered.

9. *Growth in milk without affecting this medium a fact in favour of its being the cause of scarlet fever.*—In speaking of the diplococcus scarlatinæ a leading article in the *Interstate Medical Journal*, March 1st, 1900, states: "It is interesting to note in the description of the biologic characteristics of this diplococcus scarlatinæ that the micro-organism grows in milk, but does not produce any visible change in it, such as coagulation or digestion, &c. This will serve to explain the dissemination of this disease, which has been from time to time traced to the infected milk. It is important from a public health standpoint. And the fact that cows are known to be susceptible to scarlet fever, taken into consideration with the fact that the diplococcus scarlatinæ is probably excreted in the milk of these animals, will explain how this milk which spreads the disease is infected. Of course, it might also be infected by means of contamination with the hands of patients with scarlet fever or from milkers or dairymen in whose families scarlet fever is present."

10. *Finding of the diplococcus scarlatinæ in cases of surgical scarlet fever demonstrates its diagnostic value.*—In the May number of the *Chicago Medical Recorder* for 1900 there appeared a report of a case of double crypto-orchidism complicated by scarlet fever by Dr. Edward Ochsner. The patient 18 hours after the operation for the relief of his trouble suddenly developed a high temperature together with vomiting. On the following morning the patient showed a scarlet rash all over his body. The only things that had come in contact with the patient prior to the appearance of the rash were saturated solutions of boric acid and alcohol dressings, no iodoform being used. The question naturally arose whether the rash was of a simple septic nature or true scarlet fever. I made cultures from the blood, obtaining a pure growth of the diplococcus scarlatinæ. A similar finding was obtained from the patient's urine, which showed traces of albumin. Subsequently the patient scaled. Since the publication of the above report I have again had an opportunity to examine blood and throat cultures taken from a patient

[21] Loc. cit.
[22] The Journal, Feb. 24th, 1900.
[23] Interstate Medical Journal, March, 1900, p. 120.

developing a sudden rise in temperature and scarlet rash after a slight operation upon the heel. The result of the examination of these cultures also showed the case to be one of scarlet fever. I mention these cases because in all probability a large number of cases of so-called septic rashes are nothing more or less than true scarlet fever.

In concluding, I wish to state that all the experiments quoted are open to investigation and that I feel confident that unprejudiced and painstaking investigators will further confirm what has been said. Allowing that these statements are based upon facts, I think it must be admitted that the diplococcus of scarlatinæ fulfils all of Koch's laws and is therefore entitled to some consideration at the hands of those engaged in a search for the solution of the etiology of scarlet fever.

Chicago.

# A LYMPHATIC ANÆMIA MET WITH IN CHILDREN.

BY ALEXANDER MACGREGOR, M.D. ABERD., M.R.C.P. LOND.,

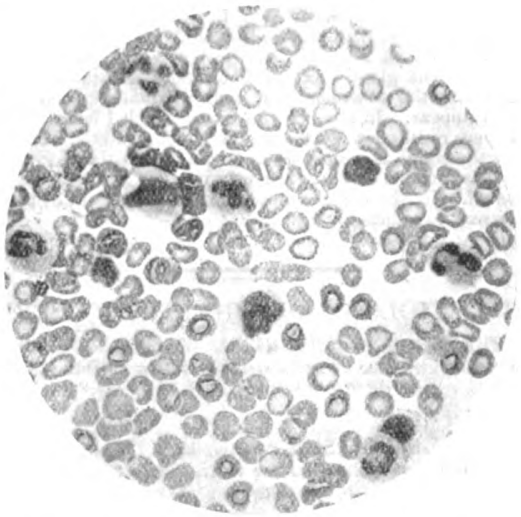
PHYSICIAN TO THE NORTH LONDON HOSPITAL FOR CONSUMPTION AND TO THE WESTMINSTER GENERAL DISPENSARY.

NEITHER in any special work on the diseases of children nor in any work on systematic medicine have I been able to find an account of, or any reference to, a form of anæmia which is not uncommon in children and which, I believe, is never met with in the adult. The following short description of the characteristic signs and symptoms of the disease may therefore be found of sufficient interest to be worthy of a place in the pages of THE LANCET.

The disease is one of childhood and the signs and symptoms are so characteristic that it cannot be mistaken for any other form of anæmia or affection of the lymphatics. Of 23 cases of which I have taken notes during the last few months the ages range from three to 16 years and 18 of these patients were between three and 11 years of age. As to sex, 19 of the patients were boys and four were girls. In no case have I been able to find a history of an acute stage or sudden onset. The disease runs a very chronic course and recovery is the rule. The history of the cases shows that the glandular affection is in no way connected with those enlarged glands which usually become (or are from the first) tuberculous, and the characteristic adenitis and the chronic course mark it sharply off from glandular fever. The anæmia may or may not be very marked, but it is, of course, readily recognised; the adenitis is always marked, but it is easily overlooked because none of the glands are large enough to attract the eye. The form of adenitis and the groups of glands affected are characteristic of the disease. The glands are small and hard, and they are always numerous in the cervical triangles and in the groins. The axillary glands are never affected. That the bronchial glands are frequently, if not always, enlarged one may safely infer from the fact that cough is in many cases a troublesome symptom when there is nothing in the lungs to cause it. The mesenteric glands are probably also affected but abdominal symptoms are rare. In a large proportion of cases the spleen is distinctly increased in size. Catarrhal pneumonia of one or both bases is not uncommon; in one of the cases there was pleural effusion and in another there were well-marked signs of thickened pleura. Examination of the blood shows a decrease of the red and a large increase of the white corpuscles, and of the latter the increase of the large uninucleated corpuscles is very striking. This is well seen in the accompanying illustrations.[1] Normally, it is said, lymphocytes form from 15 to 20 per cent. of the white corpuscles, the large uninucleated from 6 to 8 per cent., the multinucleated from 70 to 80 per cent., and the eosinophilic from 2 to 4 or 7 per cent. I have stained a large number of films of the blood of children suffering from this lymphatic anæmia and on counting the leucocytes have found that the lymphocytes formed from 12 to 13 per cent., the large uninucleated from 20 to 39 per cent., the multinucleated from 41 to 63 per cent., and the eosinophilic from 2 to nearly 7 per cent. The increase of the large uninucleated corpuscles from 6 to 39 per cent. is thus seen to be very marked. In two cases the multinucleated and the large uninucleated corpuscles were present in practically equal numbers, and very few small lymphocytes were seen. The blood films were stained with eosin and hæmatoxylin, and the illustrations show two typical fields.

[1] The Diseases of the Blood. By Alfred C. Coles, M.D.

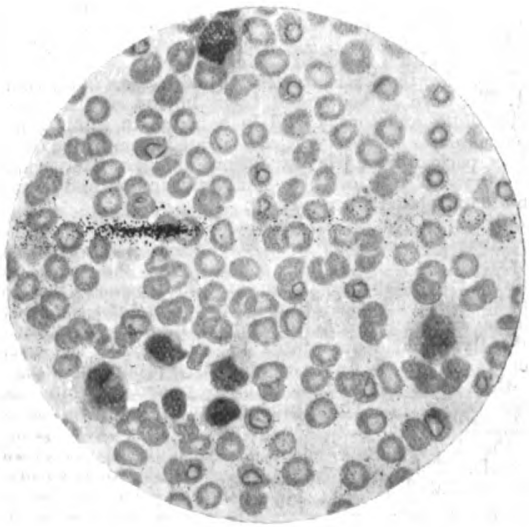
FIG. 1.



Shows five multinucleated, four large uninucleated corpuscles, and one small lymphocyte.

With regard to the family history in five cases a parent or one of the other members of the family suffered from phthisis, and in eight cases phthisis appears in the history of the grandparents, uncles, or aunts. Otherwise nothing of interest was noted in the family histories, and some of the most typical cases showed no trace of any direct or indirect connexion with tuberculosis.

FIG. 2.



Shows five large uninucleated corpuscles and two lymphocytes.

As to the signs and symptoms they are so characteristic that it would be uninteresting and tedious to quote cases in detail. There is always a history of gradually failing health, the child becomes listless and easily fatigued, loses flesh, and becomes anæmic. Cough is frequently a troublesome symptom and it is usually worst at night; occasionally there are night sweats. There is great loss of appetite; the tongue

is as a rule clean, and the bowels are usually constipated. In a typical case the cervical triangles are packed with small, hard glands, and in the groin a chain of similar glands is always found along Poupart's ligament. Then in most cases the spleen is distinctly enlarged.

With regard to treatment, arsenic and iron naturally suggest themselves as the best remedies and on these, with cod-liver oil occasionally given in addition, the patients usually do well. Improvement is slow in all cases, but as a rule the appetite rapidly improves, the child regains his naturally bright spirits, is not so easily fatigued and becomes less anæmic. The glands, except in a few cases, are not readily affected by the treatment but they gradually become softer and disappear. In none of the cases which I have watched has there resulted a local or general tuberculosis. In many cases the cough is a most troublesome and obstinate symptom and it is difficult to convince parents that the lungs are not affected. In those cases a sedative mixture at night may be necessary to secure undisturbed sleep.

# THE ETIOLOGY OF RHEUMATIC FEVER

BY FREDERICK J. POYNTON, M.D., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, AND CASUALTY PHYSICIAN TO ST. MARY'S HOSPITAL;
AND
ALEXANDER PAINE, M.D. LOND.,
ASSISTANT BACTERIOLOGIST TO ST. MARY'S HOSPITAL.

(*Concluded from p. 869.*)

## GENERAL CONCLUSIONS AND REMARKS.

*Concerning the isolation of the diplococci.*—1. We have demonstrated these diplococci in eight successive cases of acute rheumatism. 2. They have been present in five cases in pure culture. 3. We have obtained them (*a*) from the blood of living patients suffering from acute rheumatic pericarditis; (*b*) from the pericardial fluid and from the fragments of granulations removed from the valves after death; and (*c*) from the throat of the living patient suffering from rheumatic tonsillitis.[1] 4. We have isolated them and grown them in an acid medium and also upon blood agar. 5. They have also grown in the pericardial fluid which we proved on those occasions to be acid. 6. They do not thrive on ordinary media. 7. We have isolated them in pure culture from the joint exudation, heart blood, urine from the bladder, and cerebro-spinal fluid of rabbits that have been inoculated with a sufficient dosage.

*Concerning the demonstration of the diplococci in the tissues.*—1. We have demonstrated them in the cardiac valves, pericardium, and tonsils, and in a nodule in fatal cases of rheumatism.[2] 2. We have demonstrated them in the cardiac valves, pericardium, joint exudation, kidneys, liver, connective tissues, pleuræ, cerebro-spinal fluid, lungs, and urine of rabbits inoculated intravenously.

*Concerning the results produced by inoculation of these organisms intravenously into rabbits.*—1. They produce a polyarthritis, bursitis, and tenosynovitis. 2. This polyarthritis may completely disappear. 3. In some of the joints that have been affected for a considerable time the fluid is opaque and contains fibrin, endothelial cells, mononuclear and polynuclear leucocytes. In other joints the exudation is clear. 4. In one case they produced a paresis of the lower extremities which passed off in about three weeks. 5. They produce multiple valvulitis and pericarditis, both non-suppurative. 6. They produce in the liver and kidneys a condition of coagulation necrosis. This in the case of the kidneys chiefly occurs in the convoluted tubules. 7. They produce plastic pleurisy and pneumonia. 8. The urine is acid and loaded with urates. 9. They have not produced suppurative foci in the viscera. 10. They produce in the myocardium a condition of fatty degeneration and destruction of the muscle fibres analogous to that found in the human heart as a result of severe rheumatic carditis. 11. The clinical symptoms are characterised by multiple painful joint swellings, wasting, with (in the less severe cases) a maintenance of the appetite. There is moderate pyrexia. 12. The heart is affected early; tachycardia, dyspnœa, and irregularity of cardiac action, together with valvular murmurs, pericardial and pleural friction, have all been observed. 13. The clinical symptoms are, on the whole, remarkably constant when the organism is passed from animal to animal, though the tendency is for increase in the severity of the cardiac lesions and diminution in the arthritis.

[1] Since the completion of this paper we have twice isolated them from the urine of a patient suffering from acute rheumatic pericarditis and have demonstrated them in the pleural exudate.

## I.—THE MORPHOLOGY AND OTHER CHARACTERISTICS OF THE DIPLOCOCCUS.

We are not as yet in a position to state fully the morphological characteristics of this micro-organism. Our research has been concerned more especially with the elucidation of the symptoms and morbid changes that are the result of their access to the living body. We have, however, ascertained the following details.

1. They are minute cocci associated in pairs, the individual elements of which vary somewhat in size but average 0·5 $\mu$ in diameter, as measured by Zeiss's micrometer eyepiece.

2. In liquid media they grow in chains of varying length. In solid media they grow in masses that resemble the arrangement of staphylococci.

3. They grow both aerobically and anaerobically. They may be cultivated upon ordinary media but do not thrive and rapidly lose both their virulence and characteristic appearances. When isolating them from the tissues we have succeeded best with a medium of milk and bouillon slightly acidified with lactic acid, and, on the whole, the anaerobic tubes have proved more suitable to them than the aerobic. When they have been isolated they grow well upon blood agar aerobically at a temperature of 37° C., at which temperature the milk tubes were also incubated. Upon blood agar they form in 24 hours small, raised, yellowish-white, discrete colonies, the average size of which is 0·456 millimetre. The colonies are more or less circular and have, under a high magnification, a slightly granular appearance. By transmitted light they show a darker centre.

4. They stain with the various aniline dyes, though by Gram's method they are easily decolourised. The stain which we have used for them in the tissues and which has given the best result has been carbol-thionin. The metachromatism that is produced with this stain has assisted us in differentiating them from the tissues in which they were lying, for when deeply stained they appear a deep blue, whereas the tissues are usually a light blue or have a red tinge.

## II.—THE RELATION OF THESE DIPLOCOCCI TO THOSE ISOLATED BY OTHER OBSERVERS.

There can, we think, be but little doubt that these diplococci are identical with those discovered by Triboulet in 1897 and by Wassermann in 1899. Triboulet isolated them from the blood in acute rheumatism and grew them anaerobically. He also produced in one instance a valvular lesion in a rabbit but did not produce polyarthritis. In spite of this absence of joint lesions he thought these diplococci were the cause of rheumatism. Wassermann originally isolated them after death from a case of rheumatism and produced polyarthritis and tenosynovitis in a series of rabbits. He grew them best on a strongly alkaline medium aerobically, but did not apparently obtain any valvular lesions. In addition to the isolated lesion obtained by these observers the entire picture of rheumatic fever resulted in our cases. We have succeeded with acid but failed with strongly alkaline media.

## III.—IS THIS ORGANISM THE CAUSE OF RHEUMATIC FEVER.

In the face of the statements by Achalme, Thiroloix, Bettencourt, Litten, and others, we cannot claim that this diplococcus is the only cause of rheumatic fever. More extended observations will doubtless settle this most important point. That it is one cause we believe to be proved to all practical purposes by this investigation and we believe it highly probable that it will prove to be the cause of all cases of rheumatic fever which conform to the usual type of the disease, for the disease in man, as we have insisted before, is a very definite one and therefore probably caused by a specific micro-organism.

## IV.—THE CLINICAL LIKENESS BETWEEN RHEUMATIC FEVER AND THE DISEASE PRODUCED BY THE DIPLOCOCCUS IN RABBITS.

The resemblance between the disease produced in rabbits and the rheumatic fever of man is, we think, a very striking one. There is moderate pyrexia and wasting, and the

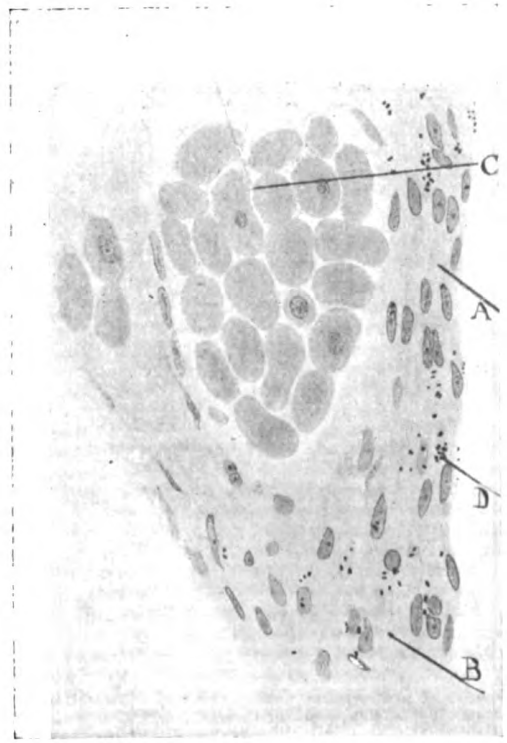
occurrence of a painful polyarthritis, which is metastatic and may entirely disappear. The tissues around the joints, such as the tendons and bursæ, are also affected, and the large joints are especially liable to this arthritis. The heart is affected early, even before the joints or irrespectively of the joint-affection. In the severe cases there occur pericarditis, valvulitis, pleurisy, and pneumonia, and the myocardium suffers as it does in acute rheumatism. The urine is acid and loaded with urates. There is no suppuration in the viscera and the peritoneum escapes as it does, as a rule, in rheumatism. In one case following the arthritis there occurred a passing weakness of the hind limbs. We do not venture to explain this, but think it suggestive of paralytic chorea.

The course of the disease is, as in rheumatic fever, prolonged and inclined to recovery unless the dose is a large one. Finally, there is a tendency to exacerbations of symptoms similar to those so frequently observed in the rheumatism of childhood. In this it is well known that even when progress seems to be satisfactory there may be, without assignable cause, a sudden exacerbation of symptoms which may almost as quickly disappear; in the rabbit also these variations may be noticed.

## V.—THE DEMONSTRATION OF THE DIPLOCOCCUS IN THE TISSUES.

The demonstration of these organisms in the human tissues is not easy. We think that one reason for the difficulty lies in the fact that rheumatic fever is essentially a disease to which there is great resistance. Even in fatal cases the reparative processes are often well advanced at the site of some of the local lesions. Such tissues, too, as the granulations upon valves, the nodules, and the pericardial exudation are among the more difficult of the structures that require investigation under the highest powers of the microscope. The micro-organism, again, is a very minute one and often present in compact masses which are liable to be mistaken for Mastzellen. Their discovery in the rabbit is far easier, for the animal can be killed early in the disease, and it is a point of great interest that numerous diplococci can be demonstrated in the pericardium before any cellular reaction of consequence has had time to develop. The animal tissues have afforded us the very greatest assistance both in localising the diplococcus and in getting a true picture of its appearance in the viscera.

FIG. 6.



A section through the endocardium part of the heart wall and base of the mitral valve of a rabbit. During life there were evidences of pericarditis and valvulitis with well-marked polyarthritis. The necropsy verified the clinical diagnosis. A, The endocardium. B, The base of the valve. C, Transverse section of cardiac muscle. D, The diplococci. Stain, carbol-thionin.

We are not at present in a position to state with confidence the number of diplococci that are present in the human tissues, but have good reason to believe that at some period of the illness they are present in large numbers. Usually they are seen in small clumps, but when they reach a free surface they are sometimes in large masses, although the individual diplococcus is very small. In the short description that is given below of their occurrence in particular regions, such statements as are made are supported by the proof of microscopic demonstration.

1. *Occurrence in the heart.*—The valves of the heart are attacked from within and the diplococci are not at first found upon the surface (Figs. 6 and 7). In both man and rabbits we have examined valves in a very early stage of the local disease and found the diplococci beneath the endocardium in the substance of the valve and at the base in the region of the valve ring. When the connective tissue proliferation they produce in the valve becomes a granulation and breaks down then they may be found on the surface; they may also be found in the connective tissue cells of the valve and chordæ tendineæ. It is especially difficult in our experience to demonstrate them in the necrotic material of an early granulation. They are found in man in the deeper part of the visceral pericardium, in the fibrino-cellular exudation, and in the parietal pericardium. In the rabbit they can be seen in the visceral pericardium and in the parietal pericardium following the course of the blood-vessels. In the heart-wall they are seen sometimes in the areolar tissue near the blood-vessels in the intermuscular septa. In the very earliest stages these organisms can be discovered in these tissues without having apparently caused any reaction, but a proliferation of connective tissue-cells and a free exudation of leucocytes is usually easily recognised as a result of their presence. During the acute phase of rheumatic pericarditis they circulate in the general blood-stream (Figs. 8 and 9).

FIG. 7.

Section showing micro-organisms in the mitral valve from a case of chorea with acute endocarditis. The endothelium is intact and the organisms are invading the substance of the valve from within. × 2100 times.

2. *Occurrence in the nodule.*—The discovery of the diplococci in the rheumatic nodule is, we think, of especial interest, for this lesion above all is looked upon as highly characteristic of rheumatic fever. It is a strong point in favour of the view that these diplococci are the cause of the symptoms of rheumatic fever. Further, it completes the proof of the analogy of this lesion with the valvular and pericardial inflammation—an analogy which has been long suspected by clinicians. In the rabbit the connective tissues near the affected joints are sometimes swollen and gelatinous. In one case a nodule appeared over a vertebral spine and after a month gradually disappeared. Sections of the tissue in this condition show the three zones that are

found in the rheumatic nodule. This series of changes in these tissues is a strong support of the views expressed by Dr. Poynton and Dr. Still in the Transactions of the Pathological Society of London for 1899 upon the Structure of the Rheumatic Nodule.

3. *Occurrence in the kidney.*—This we believe to be one of the most interesting aspects of the subject and we briefly recapitulate here the chief facts that have come to light.

FIG. 8.

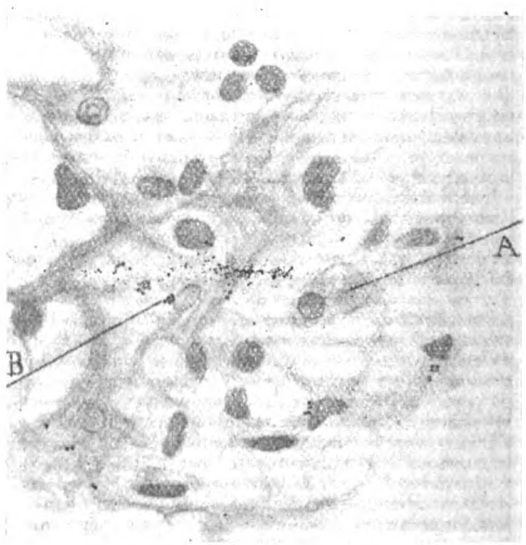
A part of the parietal pericardium of a rabbit stretched out and stained. The diplococci are distinctly seen. A, In the blood-vessel. B, In the wall of the vessel. C, In the pericardial tissues external to the vessel. They are arranged mostly in the small clumps which are so frequently seen both in the human and other animal tissues. Stain, carbol-thionin. The rabbit died from pericarditis and valvulitis.

In the first place, there is the definite proof of their occurrence in the kidneys of rabbits after death. They are found especially in the convoluted tubules lying in the cells and produce coagulation necrosis of the protoplasm. Secondly, their presence is associated with a urine which is acid, contains granular casts, and is loaded with urates. Thirdly, they have been isolated and cultivated from the urine in the bladder of rabbits. Since we ascertained these facts we have had no opportunity of following up the investigation in the human kidney.[3] The indications, however, seem clear. It is highly probable that the kidney takes an important part in the preservation of the organism against the results of this infection. The character of the urine in rheumatic fever, the occasional occurrence of nephritis, possibly, too, the occurrence of infarcts, together with the researches of Chvostek and Singer, all point to an investigation on these lines as likely to produce some valuable facts. Have the relapses that occur so frequently any dependence upon the condition of the kidney? Does the occasional association of gout and rheumatic fever bear any relation to the occurrence of renal lesions? These, among others, are the problems that suggest themselves to us. Finally, the acute nephritis which sometimes occurs in childhood without any apparent cause may possibly find its solution as being in some instances, the result of this infection.

4. *Occurrence in the liver.*—In the rabbit we have found in the liver areas of coagulation necrosis. The liver cells undergo a rapid destruction and the micro-organisms can be demonstrated within them. In this organ they do not stain well and our examination of these sections leads us to suppose that they are destroyed by the agency of the liver cells. As yet we have not found in the liver of the rabbit that extreme vascular engorgement seen in rheumatic fever, but the hepatic venules are more dilated than usual. In one severe case of rheumatic fever (Case 6) we found the condition of the liver cells resembled closely that found in the rabbit, and we believe that in this case also the diplococci, whose presence we had proved by isolating them from the pericardial fluid, were being destroyed in this organ. The small size of the micro-organisms and the fact that they stained with difficulty does not, however, permit as yet a dogmatic statement upon these points.

5. *Occurrence in the joints.*—We have no personal knowledge of their occurrence in the joints in the human being, but Triboulet discovered a diplococcus in the joint exudation. They occur, sometimes in vast numbers, in the exudation in the rabbit. The fluid in the joints of rabbits may be clear or opaque and may even have the consistence of pericardial lymph. This thick fluid is found in the joints that have been affected for some time and such joints remain distended with this fluid. Possibly this may be thought to be an important difference between the condition produced artificially in rabbits and the rheumatic fever of man. In no single case, however, have we found suppuration in any of the viscera associated with this condition of the joints; further, the exudation is definitely fibrino-cellular in character. We lay especial stress upon this point, for we are sure that to jump to the conclusion that this condition found in the rabbit was a suppurative one simply from the macroscopic appearance of the exudation would be an error. The disease must be studied both clinically and pathologically and the affected organs examined microscopically before pronouncing upon the nature of the infection. The bursæ and tendon sheaths are affected in the neighbourhood of the

FIG. 9.



A section of a rheumatic nodule, showing diplococci in the tissue. The patient (Case No. 7), a boy, aged nine years, was admitted for rheumatic pericarditis and arthritis. The course of the disease was characteristic of rheumatic fever in childhood, and death occurred after a prolonged illness. Towards the end active rheumatism reappeared and nodules developed. The section has not passed through the centre of the nodule, but through the connective tissue zone of the formation. The figure shows retiform connective tissue with small clumps of diplococci scattered through it. A, Areolar tissue. B, Diplococci. Fixative, perchloride of mercury.

[3] Ibid.

joints in rabbits as in man. As further evidence upon the question of suppuration the following experiment is of value. A rabbit was inoculated under the skin of the abdomen with the contents of six blood agar tubes of a virulent culture. A large firm swelling resulted, a gigantic nodule, which increased in size for some days and then gradually subsided without any indication of abscess formation. There were no symptoms of a constitutional affection and except for this slightly tender swelling no clinical symptoms followed. Apert, in a similar experiment with the diplococcus, isolated by Triboulet and himself, produced a like result.

6. *Occurrence in the lungs and pleuræ.*—In the lungs and pleuræ of one of the rabbits that had been killed when suffering from pericarditis, valvulitis, pleurisy, and pneumonia we demonstrated diplococci which we believe to be identical with those found in the other viscera. They were present in masses and in vast numbers beneath the visceral pleura and in the alveoli of the lungs. The alveoli were filled with an exudation resembling very closely that seen in lobar pneumonia, though the exudation had a less reticular arrangement. In a case of rheumatic morbus cordis complicated with pneumonia we have also demonstrated diplococci in the alveoli of the lungs in great numbers. More than this we are not prepared to state, for the organisms were not isolated in this case, and it cannot, therefore, be asserted that they were identical with those which we have found in rheumatic fever. When it is called to mind how frequently both pleurisy and pneumonia occur in rheumatism this demonstration of numerous diplococci in the lungs and pleuræ of the rabbit is suggestive.[4]

7. *Occurrence in the throat.*—This, again, is of considerable interest and some of the facts that have come to light have a close bearing upon the treatment of the disease. We briefly recapitulate here the most important of the results. In the first place we have in one case (Case 7) found after death both tonsils large and inflamed and this when the illness had been one of long duration. Before death there had been an exacerbation of rheumatism and this development of tonsillitis is known to occur not only at the commencement but also during the course of a prolonged rheumatic attack. In a film from the deeper part of these tonsils we found diplococci and they were also present in the sections that were made of the tonsils. Secondly, in none of the rabbits, all of which were injected intravenously, was there any inflammation of the tonsils. Lastly, we isolated diplococci from the throat of an adult the subject of rheumatic fever who was suffering from an acute faucial catarrh. These micro-organisms rapidly produced death in a rabbit. After death valvulitis, pericarditis, and cardiac dilatation were found and the organisms once more isolated. It has been already stated that many observers have insisted upon the throat as an important site of infection in rheumatic fever, and these facts strongly support this view. Further, they point to a very watchful regard for the throat in rheumatic patients and to the assiduous treatment of it, not only in the acute stage at the commencement of the illness, but also throughout the period during which active manifestations of rheumatism, other than angina faucium, are present.

8. *Occurrence in the brain and its membranes.*—Our facts with regard to this are scanty, but, coupled with the observations of Dana, Apert, Westphal, Wassermann, and Malkoff, seem worthy of record. In one rabbit after the subsidence of arthritis a paresis of the hind limbs ensued which lasted for three weeks. This was one of our earlier cases and at the time we hardly grasped the significance of the symptom. From another rabbit which died from severe valvulitis we isolated the diplococcus in pure culture from the fluid in the lateral ventricles. In a case of chorea that died in St. Mary's Hospital in 1898 in which the movements were very severe and the heart but little affected we demonstrated numerous diplococci in the perivascular lymph spaces of the pia mater, in its capillaries, and also in some parts of the motor area of the brain. In a case of chorea of similar type we demonstrated them in large number in the mitral valve. In neither case, however, were these micro-organisms isolated. Diplococci have also been discovered in chorea by Dana, Apert, and Wassermann, and in Westphal's case, examined by Wassermann, polyarthritis was produced in rabbits. It is probable, then, that there is a close association between rheumatic chorea and the occurrence of diplococci in the brain and its membranes. It is also probable that the frequency of the occurrence of chorea in childhood depends upon the more extensive dissemination of these micro-organisms in the young, as pointed to by the clinical manifestations of the disease at this age.

### VI.—The Relation of Infective to Rheumatic Endocarditis.

It is clear that the term "infective endocarditis," which has for some time been under suspicion, can now no longer be used in contradistinction to "rheumatic endocarditis," for both are plainly infective. The relation of this type of heart disease to that found in rheumatism has, we believe, been made much clearer by this investigation. That "malignant endocarditis," as we prefer to name it, is due to various causes is beyond doubt, but the frequent association of this type with rheumatism has hardly, we think, received a sufficiently minute investigation. It is indeed thoroughly recognised, but the explanation of its occurrence as due to a mixed infection has possibly been too willingly accepted.

There are cases which have the history and many of the symptoms of rheumatic fever but differ in the progressive nature of the valvulitis and in the occurrence of marked pyrexia, frequent infarction, and nephritis. With such there may be no suppuration. These cases suggest that under certain circumstances rheumatism may depart from its usual type and yet the infection be still rheumatic—a view which is also maintained by Professor Litten of Berlin.

We can offer no complete explanation of this alteration in the type of the disease, but think that a clue may be found in the distribution and behaviour of the diplococci in the cardiac valves. In simple rheumatism they are not found at first upon the surface of the valve, and the disease tending, as it does, to recovery, they are destroyed by phagocytosis, and possibly in other ways, the valve itself undergoing sclerosis. In the malignant type they reach the free surface and then appear to multiply with great rapidity, for they are found in large masses. If then they are detached by the force of the blood-stream they may possibly give rise to a condition of rheumatic septicæmia recognised clinically as malignant endocarditis. Why they should overstep the barrier of the endocardium in this way we do not know, but it is suggestive that the valves have usually been already injured by a previous rheumatic attack and that the patient is usually in feeble health at the time of the final infection.

Finally, we must say that throughout this investigation we have on all sides received the greatest help. To Mr. H. G. Plimmer we are indebted for assistance, criticism, and advice, and we can only express our obligation by claiming to be his pupils. The physicians at St. Mary's Hospital and the Hospital for Sick Children, Great Ormond-street, have placed their clinical cases at our disposal, and to Dr. H. Thursfield, the registrar at the Children's Hospital, we are indebted for leave to make use of any necropsies that might be of service. To Mr. Forbes Tulloch, a student of St. Mary's Hospital, we are indebted for the photo-micrographs. This generous help has greatly lightened the labour of this investigation and has been an additional incentive to pursue the subject.

## THE DETERMINATION OF CHLOROFORM.

### A METHOD OF DETERMINING WITH PRECISION MINUTE QUANTITIES OF CHLOROFORM IN THE BLOOD, SECRETIONS, OR ORGANS OF ANIMALS VARIOUSLY ANÆSTHETISED WITH CHLOROFORM.

BY JAMES EDMUNDS, M.D., M.R.C.P. LOND., &C.,

MEDICAL OFFICER OF HEALTH AND PUBLIC ANALYST OF ST. JAMES'S, WESTMINSTER; CONSULTING PHYSICIAN TO THE LONDON TEMPERANCE HOSPITAL.

THE determination with rapidity and precision of minute quantities of chloroform is a problem which has hitherto not been accomplished, or only accomplished by processes so elaborate as to be impracticable. Two courses have been taken. In one set of methods the CH group has been measured by oxidimetry, much as diabetic sugar has been measured by means of the alkaline tartrate of copper devised by Fehling. In the other the $Cl_3$ has been measured after various prolonged and troublesome devices for breaking

up the $CHCl_3$ and reducing the chlorine to the saline form, so as to make it amenable to measurement by means of routine methods.

In view of the facts (1) that chloroform ($CHCl_3$) consists of chlorine to the extent of 89 per cent.; (2) that chlorine in the saline form is measurable with an ease and exactitude which rank its determination among the most charming and precise of chemical processes; (3) that the determination of chlorine is free from any sort of fallacy; (4) that the CH form only 11 per cent. of the $CHCl_3$; and (5) that their measurement by oxidation is full of fallacies—it would seem obvious that the true objective at which to aim was the measurement of $CHCl_3$ by means of its chlorine. Yet so difficult have been the methods hitherto in use for the reduction of its chlorine to the saline form that this natural objective has been to a great extent set aside. My object is to describe a method by which the chlorine is promptly and easily reducible to the saline form and made to serve as the measure of its chloroform. The weight of the chlorine being accurately determined, multiplication by the factor 1·12314 gives the weight of the chloroform.

If a solution of permanganic acid and potash in excess be made with 3·137 grammes of the potassium permanganate, 55·71 grammes of potassium hydrate, and water to one litre at 60° F. we get a solution in which nascent oxygen readily oxidises carbon and hydrogen into carbon dioxide and water, while potash potently abstracts and fixes chlorine as KCl. If to this solution we add less than half the permanganate equivalent of chloroform, disruption takes place in the course of a few days at the ordinary temperature of a warm room, and, on heating to 100° C., almost immediately. All that remains, practically, is to introduce the chloroform without loss, and so to secure the flask containing the mixture that it can be exposed in a water-bath which is slowly raised to the boiling-point without any volatilisation of chloroform pending its chemical disruption. The disruption of the $CHCl_3$ having been completed in the presence of the hot solution of potash, its $Cl_3$ is so perfectly fixed as KCl that it is thenceforth absolutely amenable to the everyday measurements of the laboratory. The presence of ether or alcohol, or of other volatile substances free from haloids does not interfere.

For the purpose of controlling the experiments chloroform must be weighed out uniformly and accurately in minute quantities. In aqueous solution chloroform diluted to 1 in 1000 is fairly manageable. In order to get a saturated aqueous solution I put pure chloroform into an all-glass burette with a sediment-end projecting downwards below the glass tap. Chloroform is then poured into the burette in quantity sufficient to fill up this tube below the tap but so that no chloroform can flow out through the tap. On filling the burette up to zero with distilled water and shaking we have a solution of chloroform which can be run off by gravity through the glass tap, while surplus chloroform remains always present at the bottom of the burette. As the chloroform-water is measured off for the purpose of experiment we fill up the burette with fresh water and, from time to time, add further portions of chloroform. A properly constructed glass stopper at the top converts the burette into a well-stoppered bottle in which, on turning the stopper round 90° one way or other, we have a burette which discharges freely, or is a perfect vessel for the storage of our solution of chloroform.

If a good balance, such as will weigh easily to 0·0001 gramme, be available, it is best to weigh out pure chloroform for the control experiments. I use a miniature test-tube having a capacity of about one cubic centimetre and a length of some two inches, standing in a 60-minim measure in the scale pan. The tube and its stand having been carefully cleansed, dried, and weighed, weights amounting to a further 0·1186 gramme are added to the other scale pan. Then by means of a very delicate pipette I drop the pure chloroform into the tube until it somewhat overbalances the weights. By means of filaments of fine filtering paper held in a pair of forceps the surplus chloroform may now be easily absorbed and the exact weight secured. Then by means of the forceps the tube with its contents is lifted out of its stand and dropped bodily into the solution and the bottle is promptly closed. If reliable apparatus be not available for preventing loss of chloroform by volatilisation under the high tension of chloroform vapour at 100° C., it is best to use strong glass bulbs of 100 cubic centimetres capacity and with long tubular necks that, under the blow-pipe flame, may easily be drawn out and sealed hermetically. I have used six-ounce strong Jena bottles, with a flat, wide, ground-down nose and a small aperture. Upon the flat nose there fits a slab of strong glass ground finely to a true flat surface on one side so as, by mere apposition, to make the nose steam-tight if properly held in place. A little flour-and-water luting on the end of the nose perfects the joint and the glass slab is retained solidly *in situ* by a brass frame and a screw-down plate. A hook upon the brass frame allows the bottle to be swung in a water-bath and beneath the gas is lighted so as to raise very slowly the surrounding water to the boiling point. With reasonably good manipulation the installation is free from any sort of risk or uncertainty, and the operation when set going may be left to itself.

In an hour or two the purple colour of the permanganate is seen to have been replaced by the bluish-green colour of the manganate, while the solution is made turbid by a large quantity of out-thrown hydrated dioxide of manganese. The gas is turned out and everything is left till cold. The flask is then unshipped and opened. If the solution be now filtered a brilliant blue-green liquid passes through. But filtration is not necessary. Decinormal solution of sodium sulphide is now dropped cautiously into the solution and the bottle is agitated enough to mix the sulphide uniformly. Decolouration takes place until the blue-green manganate is largely replaced by a colourless liquid in which float brown flocculi of manganese dioxide. Reduction having been effected the solution is poured on a filter, the bottle is washed carefully into the filter, and the filter is finally rinsed through with boiling distilled water. The filtrate is acidified with normal sulphuric acid and then, if any haze of surplus sulphur comes out, the solution is run through a second filter of fine close texture until bright. This second filter is washed through with boiling distilled water and the filtrate is finally made up to 200 cubic centimetres at 60° F. The whole of the chlorine will be found in this filtrate unless the reduction has been mismanaged. 20 cubic centimetres are enough to titrate.

If sulphur comes out on acidifying, the solution has been over-sulphurised and must be treated with fresh permanganate until an enduring rose colour comes. On running this rose-coloured solution once or twice through a fresh filter the last traces of permanganate are reduced by the action of the paper filter and a bright colourless filtrate comes through. But it is better to work the sodium sulphide as a reducer rather than as a sulphuriser of the excess of permanganate and to drop it in so cautiously that the solution yields a filtrate in which residual manganate leaves a distinct blue-green colour. Upon acidifying and running this once or twice through a fresh filter the residual manganate is reduced and a bright colourless filtrate is obtained. This is washed up to 200 cubic centimetres. 20 cubic centimetres are taken for titration.

The 0·1186 gramme $CHCl_3$ taken is an equivalent of chloroform in milligramme atoms. Under the conditions and manipulation described it is easy to weigh out the chloroform to 0·0001 gramme. The charge into which the weighed chloroform is dropped is 50 cubic centmetres of the solution. This solution, as to releasable oxygen, is decinormal; as to potash it is of full normal strength. In oxidising the carbon to carbonic acid and the hydrogen to water one atom of nascent oxygen is obtained by reduction of the permanganate in alkaline solution, and there is also used up the oxygen displaced by the three atoms of chlorine which unite with potassium. The chemical reactions may be represented as follows:—

$$CHCl_3 + 5\,KHO + O = K_2CO_3 + 3\,KCl + 3\,H_2O.$$

The disruption is effected by the double action of the nascent oxygen upon the carbon and hydrogen, while the newly-formed carbonic acid and the released chlorine are greedily absorbed by the potash. It will be noticed that only a small part of the charge is used in breaking up the chloroform. The remainder of the charge is introduced in order to raise the chemical potential and thus secure the complete disruption of the chloroform.

The determination of the chlorine is a routine matter of laboratory work. I much prefer, however, the beautiful process of Volhard to any other. The method of applying Volhard's process for urines, serums, and other such matters in which a quick and accurate method of determining chlorines is desired has been already described by me.[1] But this solution containing the chloroform-chlorine presents

[1] Sutton's Volumetric Analysis, 1896, pp. 379-380.

none of the difficulties which are presented by urines and serums. Therefore any of the processes for determining chlorine may be used.

In applying this process to the determination of traces of chloroform in the blood, urine, organs, &c., of animals variously anæsthetised with chloroform, it is obvious that the saline chlorine in blood, urine, &c., must be kept back. Chloroform is so volatile that this presents no sort of difficulty. Such matters put into a properly fitted distilling flask immersed in water that can be raised to 100° C., and furnished with a good condenser, will yield all their chloroform by slow volatilisation in the course of a few hours, and the distillation may be left to itself. Provision must be made for conveying the condensed liquid into the cold permanganate and potash solution without loss. The separation having been completed the receiving bottle must be unshipped, securely closed, and heated in the water-bath slowly up to 100° C., at which temperature it may be left for a time.

Blank determinations must be made with the identical reagents and apparatus in order to be sure that these minute quantities of chlorine are not mixed up with chlorine pre-existing in the reagents. Any such chlorine must, of course, be deducted from the determinations, or reagents must be used which are so pure as to exclude all traces of extraneous chlorine.

Manchester-square, W.

# ON THE CALORIE-VALUES OF CERTAIN ARTIFICIAL INFANT'S FOODS.

BY WALKER OVEREND, M.D., M.A. OXON., B.SC. LOND.,
LATE SENIOR PHYSICIAN TO THE TOTTENHAM HOSPITAL AND RADCLIFFE TRAVELLING FELLOW.

## I.—THE COMPOSITION OF HUMAN MILK, COW'S MILK, GOAT'S MILK, AND ASS'S MILK.

IN the present paper only those foods are considered which are suitable for the first six months of infantile life. It is obvious that such foods should approximate as nearly as possible to the natural infant's food. The first point of importance, therefore, is to determine the average composition of human milk.

From the period when lactation becomes well established (about three weeks) until the period of weaning (seven months) the composition of human milk under normal conditions remains fairly uniform. According to Biedert[1] it contains 1 per cent. of proteid, 3·2 per cent. of fat, and 6·8 per cent. of lactose. One of the most important rules in artificial feeding, therefore, should be the maintenance, as far as possible, of a uniform composition of the food throughout the first six months or at least after the third week until the end of the above period. The quality, in other words, should be preserved and the quantity increased according to the age and needs of the infant.

By the term "calorie" is understood the amount of heat required to raise the temperature of one kilogramme of water one degree centigrade. One gramme of fat in its combustion generates 9·3 calories; one gramme of sugar and one gramme of proteid (counting urea as the end-product) each liberates 4·1 calories. By an easy calculation it follows that 100 grammes of human milk of average composition correspond to 61 calories. In the case of *poor* human milk, that of starvation, the fat may diminish to 2 per cent. and the sugar to 4 per cent., but the proteid may increase to 2·5 per cent. 100 grammes of such milk represent only 36 calories, whereas in over-rich milk, as in mothers who live luxuriously and take little or no exercise, the fat may reach 5 per cent., the sugar 7·5 per cent., and the proteid 3·5 per cent. Milk of this description is very indigestible, and 100 grammes represent 90 calories.

When we compare the composition of average cow's milk the fat is about the same percentage (3·88), the lactose is diminished to 4·5 per cent., whilst the proteid reaches 3·3 per cent. The proportion of caseinogen to lacto-albumin is as two to one, whereas in human milk it is as one to two. 100 grammes of cow's milk are equivalent to 68 calories. Goat's milk, which contains 4 per cent. of proteid, 4·8 per cent. of fat, and 5 per cent of lactose, has a calorie-value of 80. Ass's milk, which contains less proteid (about 2 per cent.), is more suited for very delicate infants. Its percentage of fat reaches only 1·6 and lactose 6. The calorie-value is nearly 50. The disadvantage lies in the deficiency of fat. Assuming the composition of average cream[2] to be, fat 12 per cent., lactose 2·8 per cent., and proteid 4 per cent., one teaspoonful (four grammes) is equivalent to five calories. Two teaspoonfuls of cream added to each 100 grammes (three and a half ounces) would raise the calorie-value of ass's milk to 59.

[1] Die Kinderernährung im Säuglingsalter, edition iii., p. 93.

## II.—THE MINIMAL REQUIREMENTS IN HAND FEEDING.

The following table is modified from Biedert.[3] It is evident from its results that the calorie-value should not fall below 40 per 100 cubic centimetres of liquid nourishment.

| Lunar month. | Proteid. | Fat. | Sugar. | Volume per kilogramme. | Calorie per kilogramme. | Total calories. | Average weight in kilogrammes. | Calorie-value per 100 grammes of food. | Proportion of N. to Non-N. |
|---|---|---|---|---|---|---|---|---|---|
| | Grms. | Grms. | Grms. | c c. | | | | | |
| First month. | 2·3 | 4·5 | 6·6 | 140 | 74 | 278 | 3·770 | 50 | 1 to 5 |
| Second ,, | 3·1 | 3·6 | 8·0 | 227 | 75 | 246 | 3·285 | 33 | 1 to 3·7 |
| Third ,, | 2·8 | 3·3 | 9·9 | 250 | 79 | 286 | 3·630 | 33 | 1 to 4·7 |
| Fourth ,, | 4·2 | 4·8 | 11·8 | 248 | 104 | 442 | 4·25 | 44 | 1 to 4 |
| Seventh ,, | 3·0 | 5·3 | 7·7 | 266 | 89 | 570 | 6·4 | 33 | 1 to 4·3 |

As the child grows the quantity must be increased *pari passu* with its age and with its weight. For the sake of reference the accompanying table, which indicates the amounts necessary for an average infant at different ages in the 24 hours, is inserted:—

| Age. | No. of bottles. | Quantity in each bottle. | | Total amount. | | Approximate number of calories required per day. |
|---|---|---|---|---|---|---|
| | | Grammes. | Ounces. | Grammes | Ounces. | |
| First week. | 10 | 30 | 1 | 300 | 10 | 180 |
| First month. | 9 | 45 | 1½ | 400 | 13½ | 240 |
| Second ,, | 8 | 85 | 3 | 680 | 24 | 400 |
| Fourth ,, | 7 | 120 | 4 | 840 | 28 | 500 |
| Sixth ,, | 6 | 170 | 6 | 1000 | 36 | 600 |

## III.—RESULTS OF OVERFEEDING.

The quantitative estimation of the income and excretion of nitrogen shows, as, indeed, one would expect, that in hand-fed children the deficit of nitrogen, in spite of the greatest care, is greater than in infants brought up on the breast. In other words, the breast-fed infant deposits a larger proportion of its nitrogen within the tissues and the muscles. Hand-fed children consequently require more nourishment, inasmuch as their food is not so perfectly assimilated. In overfed children, however, brought up by hand as much as 90 per cent. of the nitrogen may pass out in the excreta. This excess leads to a heavy and useless expenditure of energy on the part of the stomach, intestines, and kidneys. The child suffers from colic, flatulence, with diarrhœa at times (the stools containing undigested curd), and becomes exceedingly restless and fretful. Biedert has demonstrated that the stomach of a breast-fed child is usually empty about one and a half hours after a meal, whereas in the hand-fed this is not always the case even after two and a half hours. In children over four months old the residue will be further digested by the action of the pancreatic juice, with the gradual development of an alkaline reaction. In breast-fed infants the reaction of the stools is generally acid, in the healthy hand-fed (on cow's milk) it

[2] If good milk be allowed to stand in a cool atmosphere and in shallow vessels the cream taken after two hours contains from 10 to 15 per cent. of fat. Cream obtained by means of the centrifugal separator is much richer and may even reach 66 per cent. In purchasing cream from the dairy it is necessary to have some idea of its percentage of fat. In this paper the calorie-values have been estimated on the assumption that the cream contains 12 per cent. of fat.

[3] Op. cit., p. 94.

is alkaline. An acid reaction in the latter would indicate imperfect assimilation and future danger.

With regard to the percentage of sugar, this should not exceed 7 per cent. When an excess of sugar is ingested its absorption becomes deficient and diarrhœa may supervene with the formation of green acid stools. Such children are apt to become fat, flabby, and rickety.

When foods very rich in fat are administered the stools may become more frequent, acid, sometimes glistening and soapy-looking, at other times green. If the fat be diminished the motions become normal, but may reappear as before with increase of fat (fat-diarrhœa). In such cases the fat must be eliminated from the food for a time and skimmed milk along with one of the artificial foods, to be mentioned later, as Mellin's or Theinhardt's, should be employed.

### IV.—MILK PREPARATIONS.

1. *Sterilised milk.*—Budin[4] recommended in 1893 the employment of undiluted sterilised cow's milk. If the patient does not thrive on the breast from 50 grammes to 250 grammes of sterilised milk, according to the extent of deficiency, may be given daily, and if the mother is unable to feed the child altogether from 500 grammes to 700 grammes of sterilised milk per diem. The calorie-value is naturally satisfactory, but the amount of proteid is obviously three times the amount required, whilst the lactose is less than what is necessary. Its use has not become general.

2. *Artificial human milk.*—The late Sir E. Frankland suggested a method of imitating human milk, the principle of which was to remove a part of the cream, digest the milk with rennet, filter off the casein, and add the necessary amount of milk-sugar. As the milk becomes acid during the process of curdling it is advisable to add a few grains of bicarbonate of sodium. In a modified method[5] the cream is separated from a pint of milk and the casein of one-half of the skimmed milk is coagulated by rennet and strained off. The whey is then boiled, and to it is added the cream and the remainder of the skimmed milk, and the whole is sterilised in separate bottles. Such a mixture would contain about 2 per cent. of proteid, 4·5 per cent. of fat, and 5 per cent. of sugar, and its calorie-value would be 74. Rotch[6] gives prescriptions for the manufacture of milk of any desired composition. The mixture approximating that of human milk most nearly is 72—viz., cream (10 per cent. fat), five ounces; lime water, one ounce; water, 14 ounces; and milk-sugar, two and a half measures (each measure holds three and three-eighths drachms or 13·5 grammes). The percentage composition of this mixture is proteid, 1; fat, 2·5; and sugar, 6. The calorie-value is 52. Some of Rotch's mixtures can only be employed temporarily and as stop-gaps, useful in feeding premature children or infants suffering from chronic gastro-enteritis, infantile atrophy, and the like. For instance, prescription 69, with 1 per cent. of fat, 5 per cent. of sugar, and 0·75 per cent. of proteid, represents 33 calories only. Biedert[7] recommends mixtures of cream, milk-sugar, and water, with the addition of milk according to the age of the child. For instance, mixture No. 2 corresponds to 49 calories and is to be employed during the second month. It is obtained by the addition of one-eighth of a litre (about four ounces) of cream (10 per cent. fat), one-sixteenth of a litre of milk, 18 grammes of milk-sugar, and three-eighths of a litre of water. Its composition is 1 per cent. of proteid, 2·6 per cent. of fat, and 5 per cent. of sugar. Ashby's[8] mixture of milk-sugar, cream, and milk contains about 1·6 per cent. of proteid, 2·6 per cent. of fat, and 5 per cent. of lactose, and corresponds to 51·5 calories. In certain cases it is advisable to replace the water by means of barley-water which contains 1 per cent. starch. This quantity, however, is very small and not harmful. The cream-conserve of Loeflund might be used in the manufacture of these cream mixtures. It contains 5 per cent. of proteid, 50 per cent. of fat, 1·8 per cent. of carbohydrate, and 20 per cent. of water. Gärtner's "fett-milch" resembles Biedert's fourth mixture. It is obtainable in England from the Friern Manor Dairy. Cow's milk is diluted with an equal quantity of sterilised water and then submitted to centrifugalisation. From the peripheral layer of milk which is rich in fat the "fett-milch" is taken and from three to four grammes of milk-sugar are added to 100 cubic centimetres. It consists of 1·8 per cent. of proteid, 3·3 per cent. of fat, and 6 per cent. of sugar. Its calorie-value is 62. Cautley,[9] by taking equal quantities of cow's milk and lactose (10 per cent. solution) and passing them through the separator with the two out-going streams equal, obtains a cream-milk of the following composition: proteid, 2·0 per cent.; fat, 3·5 per cent.; and lactose, 7·2 per cent.; and a calorie-value of 70. It was found necessary in some cases to diminish the proteid. The milk is supplied in air-tight bottles pasteurised at 160° F. and rendered faintly alkaline. The price is 6*d.* per pint. For newly-born infants or those with dyspepsia, chronic gastro-enteritis, marasmus, and with liquid green curdy stools, whey has been recommended. Ashby[10] adds two or three drachms of milk-sugar to the pint and a few grains of bicarbonate of sodium. Whey has a composition (as made according to his directions) of 2 per cent. of fat, 4·5 per cent. of lactose, and 0·8 per cent. of proteid, and its calorie-value is only 40. If 10 ounces of milk are added to two ounces of sterilised whey and half an ounce of milk-sugar the percentage become 1·75 of proteid, 2·5 of fat, and 6·0 of lactose, whilst the calorie-value becomes 55. Whey may also be used as a diluent instead of sugar or barley-water.

3. *Milk dilutions.*—If cow's milk be diluted with an equal quantity of water or barley-water the calorie-value becomes 34. Heubner and Hoffmann diluted the milk with an equal quantity of lactose of 6 per cent.[11] strength. The calorie-value then increases to 46. Other sugars, as maltose and saccharose, are not to be recommended. If barley water be used as a solvent for the milk-sugar less of the latter must be added. The composition of the mixture would be 1·6 per cent. of proteid, 5 per cent. of lactose, and nearly 2 per cent. of fat. Children with very weak digestive powers or those convalescent after acute illness might be fed with milk diluted with twice the amount of a 4·5 per cent. solution of milk-sugar. The Obstetrical Society in its "Rules for the General Management of Hand-fed Infants" (1893) recommend in the first month cow's milk, boiled and diluted with at least twice as much hot water or barley-water. This mixture represents only 23 calories per 100 cubic centimetres. Proceeding, it is said that "one teaspoonful of cream to each half-bottle of food renders the mixture more nutritious." It would increase the calorie-value to about 28. No directions are given as to the quantity of the food per diem and nothing is said of the quality of the cream.

4. *Predigested milk.*—In certain cases of infantile dyspepsia and diarrhœa Starr[12] recommends a mixture of two ounces of milk, two ounces of water, half an ounce of cream, and one teaspoonful of peptogenic milk powder (Fairchild). The last contains pancreatin, bicarbonate of sodium, and milk-sugar. The mixture is heated to 115° F. and kept at this temperature for six minutes. It has an alkaline reaction and its proteid is in a digestible form. The percentage composition is 4·5 of fat, 7·0 of lactose, 2·0 of proteid, and its calorie-value is 77. Loeflund's peptonised milk contains 5·6 per cent. of albumoses and peptones, 12·2 per cent. of fat, and 5·5 per cent. of carbohydrates (milk-sugar, maltose, and dextrin). At first it is diluted 12 times with water, and the degree of dilution is gradually lessened with increasing age of the infant to six times at the sixth month. In the more diluted forms it is poor in fat and proteid. When diluted 12 times the calorie-value is only 32. Biedert's infants' food is a condensed creamy substance which when diluted 10 times contains 0·75 per cent. of proteid, 3·6 per cent. of sugar, and 1·8 per cent. of fat, and has a calorie-value of 34·5. The proteid is not casein, but alkali albumin produced by the action of potash on egg albumen. The stronger dilutions may be given to weak infants with delicate digestive powers. In Rieth's albumose milk, albumose is prepared by heating egg albumen to 130° C. and is not coagulated by heat or acids. Milk-sugar and cream are added. It is sold in Berlin in sterilised litre flasks. The motions become fœtid, but the results are good. Two

[12] Hygiene of the Nursery, fifth edition, p. 191.

mixtures are given, one corresponding to a calorie-value of 54, the other to 60. Voltmer's "mutter-milch" is a yellowish-brown substance resembling honey in appearance. After dilution with 12 times its amount of water the percentage composition is proteid 1·8, fat 2·2, and sugar 6·0, and its calorie-value is 51. The casein is partially peptonised by means of extract of pancreas. Here may be mentioned also "somatose-milk" which contains, as its name implies, a certain percentage of somatose. The latter consists of 85·7 per cent. albumose and 2·4 per cent. peptone. Five grammes are dissolved and added to a litre of cream mixture containing about 0·8 per cent. casein and 3·0 per cent. fat.

In that grave form of acute gastro-enteritis which has received the name of infantile cholera treatment often seems hopeless. There are incessant sickness, purging, and great danger of collapse. In many instances washing out of the stomach and irrigation of the colon are impracticable. A mixture of bovinine (15 per cent. soluble albumin) and brandy may be cautiously tried. One teaspoonful (or more) of bovinine is added to a wineglass[13] of recently boiled and cooled water and then one teaspoonful of the best brandy. The mixture should be surrounded by ice and one teaspoonful may be given every 10 minutes. Assuming the calorie-value of alcohol per gramme is seven and that the brandy contains 50 per cent., the heat value of the mixture becomes 17 per 100 cubic centimetres. After two days thin arrow-root, barley-water, and brandy, or peptonised milk, lime-water, and brandy, one teaspoonful of each to the wineglass, may be substituted for three or four days. Another mixture recommended in infantile atrophy and gastro-enteritis is white wine whey. The quantities are—milk 10 ounces and sherry two and a half ounces. The casein is removed. The composition of the whey would be about 0·8 per cent. of proteid, 0·2 per cent. of fat, and 4·5 per cent. of sugar. The sherry contains 12 per cent. alcohol. Ten ounces of milk equal 300 cubic centimetres, and two and a half ounces of sherry equal 75 cubic centimetres. The calorie-value of the 375 cubic centimetres is about 126, or 34 per 100 cubic centimetres. If two teaspoonfuls of cream are subsequently added to each three and a half ounces (100 cubic centimetres) the calorie-value reaches 44.

5. *Condensed milk.*—In a very large proportion of infants belonging to the poorer classes condensed milk is almost exclusively employed during the first nine months of life. It is easily diluted, it keeps well, and the child apparently thrives. Some of the best sweet brands, as the Anglo-Swiss Milkmaid Brand, contain about 8 per cent. of proteid, 50 per cent. of sugar, and 12 per cent. of fat. The directions issued by the above company are explicit enough. If we take those for the age of three months they are—two teaspoonfuls to 24 teaspoonfuls of water every two hours by day and once in three hours by night. Teaspoons, however, vary very much in size; moreover, in the case of condensed milk so much clings to the spoon in addition that no uniform composition of the mixture can be assured. The directions state that the dilutions should be at least one part in seven. The calorie-value of the pure milk is 342 per 100 grammes, and a dilution of one to seven signifies $\frac{342}{8}$, equal to 43 calories. The addition of two teaspoonfuls of cream to each three and a half ounces of fluid would raise it to 53. As is well known, children fed continuously on condensed milk, even of the best brands, become plump and fat, but they exhibit little resisting power. They succumb easily to acute gastro-enteritis and pneumonia. Moreover, there is a tendency to scurvy and rickets.

### V.—FOODS CONTAINING LITTLE OR NO INSOLUBLE STARCH.

1. *Allen and Hanburys' food No. 1.*—This is recommended for infants up to the age of four months. It contains no insoluble starch. The excess of casein from cow's milk is removed, cream, soluble albumin, and milk-sugar are added, and the mixture is sterilised, evaporated *in vacuo* to a powder, and packed in tins. It contains 13·15 per cent. of fat, 14·25 per cent. of proteid, and 65·48 per cent. of dextrin and sugar.[14] If the directions be followed—that is, if one tablespoonful of the food be dissolved in three ounces of warm sterilised water—the food contains about 2 per cent. of proteid, 2 per cent. of fat, and 10 per cent. of carbohydrate, and has a calorie-value per 100 grammes of 68. Its advantages are—(1) a uniform composition of the food during the four months, and (2) the absence of pathogenic bacteria. The disadvantage lies in the excess of carbohydrate. By taking three-fourths of the amount of food (a measure could be supplied with the food) and adding two teaspoonfuls of cream to each 100 grammes a calorie-value of 60 could be obtained and the mixture would then approximate that of human milk more nearly. In marasmus and after gastro-enteritis the amount of food could be lessened still further.

2. *Allen and Hanburys' No. 2.*—This is recommended for older children (from four to seven months old) and contains, in addition, maltose, dextrin, and soluble phosphates. The calorie-value as prepared according to the directions is 76.

3. *Horlick's malted milk.*—This is prepared by the action of malted barley (diastase) on milk, the result being evaporated to dryness *in vacuo* The casein is no longer coagulable by acids and starch is absent. It contains about 20 per cent. proteid, 6 per cent. fat, and 64 per cent. carbohydrate. The directions given are somewhat ambiguous—e.g., under three months it is recommended to dissolve from *one to two* heaped up teaspoonfuls in from *four to eight* tablespoonfuls of hot water. If we take the smaller proportion, and assuming that a heaped-up teaspoonful contains six grammes, the proteid becomes 2·2 per cent., the carbohydrate 6·6 per cent., the fat 0·75 per cent., and the calorie-value only 42. A tablespoonful of cream to each 100 grammes of food (three and a half ounces) would raise the calorie-value to 60 and the percentage of fat to 2·5. It is a reliable preparation, but the directions should be more definite, the amounts of food at each feeding should be noted, and a six-gramme measure supplied. In these two foods it is to be observed that no milk is added in the preparation.

4. *Mellin's food.*—This is a malted flour in which the starch has been entirely converted into soluble carbohydrate. Its composition is about 6·8 per cent. of proteid and 82 per cent. of carbohydrate. Under three months the quantities given are half a tablespoonful of food and one quarter of a pint each of water and cow's milk. The percentage composition would be 1·2 of proteid, 2·0 of fat, 5·5 of sugar, and its calorie-value 45. Above three months the proportions are—one tablespoonful of Mellin's food to four tablespoonfuls of water and six ounces of cow's milk, and the percentage becomes 4·5 of proteid, 2·5 of fat, and 7·0 of sugar. The calorie-value is 70. In the first the fat is deficient and in the second the proteid is in excess.

5. *Theinhardt's infant's food.*—This consists of milk, the proteid of which has been rendered soluble by a vegetable ferment, and of flour, a portion of which has been partially dextrinised. A further portion of the carbohydrate becomes soluble when heated. It contains 14 per cent. of proteid, about 7 per cent. of fat, and 56 per cent. of carbohydrate. Of the last 94 per cent. is soluble. For a child four months old it is recommended to use one and a half teaspoonfuls of food, five large tablespoonfuls of milk, and five large teaspoonfuls of water. Such a mixture represents 3·3 per cent. of proteid, 3·7 per cent. of fat, and 6·6 per cent. of carbohydrate. Its caloric-value is 73. Careful directions are given for each month as to quantity and quality. Biedert has found it useful in the summer diarrhœa of infants when prepared with water only, and used as a thin soup two teaspoonfuls to two ounces of water.

6. *Benger's food.*—This is a white powder consisting of flour partially dextrinised by cooking and containing pancreatic extract. If the directions for young infants are followed the mixture works out to 2·7 per cent. of proteid, 2·3 per cent. of fat, and 8·0 per cent. of carbohydrate. The food itself contains 10·0 per cent. of proteid, 1·2 per cent. of fat, and 75·0 per cent. of carbohydrate. The calorie-value is 56. With two teaspoonfuls of cream to the 100 grammes it represents 65 calories. Without the added cream there is a deficiency of fat, also there is an excess of proteid and carbohydrate.

I have not discussed other foods, such as those of Neave, Ridge, Mufller, Kufeke, Savory and Moore, and Robinson's patent barley, inasmuch as these are more suitable after the first six months are passed. But it is to be recommended: (1) that all proprietary articles, such as condensed milk, humanised milk, and infant's foods in powder, should bear on the label the average composition of the food and its calorie-value when prepared according to the general directions; (2) that, bearing in mind the ignorance of the principles of infant feeding as exhibited by the laity, each label should contain definite

[13] A wineglass is assumed to contain two and a half fluid ounces.
[14] THE LANCET, March 24th, 1894, p. 748.

rules as to the quantity of food required at each period of the infant's existence and the number of times it should be fed during the 24 hours; (3) that when feeding by these sterilised foods it is essential occasionally to add an anti-scorbutic element such as a dessertspoonful of grape or orange juice between meals three times a week, or if the child be above four months old a dessertspoonful of raw meat juice may be added to the food three times weekly (Allenbury); directions for the preparation of this juice should accompany each tin of food; and (4) that the non-liquid foods should be provided with a wooden or glass measure to prevent inaccuracy and secure some amount of uniformity in the composition of the resulting mixture.

# Clinical Notes:

## MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

### A HALFPENNY IMPACTED IN THE ŒSOPHAGUS.

BY T. COKE SQUANCE, M.D. DURH.,
PHYSICIAN AND PATHOLOGIST TO THE SUNDERLAND INFIRMARY; CONSULTING PHYSICIAN TO THE MONKWEARMOUTH AND SOUTHWICK HOSPITAL.

A GIRL, aged six and a half years, was brought to my consulting rooms on April 10th, and her mother gave the following history. Five weeks previously the child was playing with a halfpenny when she accidentally swallowed it. She was immediately taken by her mother to a medical man who "pushed it down with an instrument." After this the child complained of pain and of difficulty in swallowing and she could only take liquids or "boily" and was occasionally seized with suffocative attacks of coughing, during which she would become black in the face. She was again taken to a medical man who declared that "there was nothing there." The child began to lose flesh and the attacks of coughing still continued, though they were rather less violent. I examined the chest with the fluoroscope and discovered the halfpenny apparently somewhat tilted and lying behind the first part of the sternum. I then took a radiograph and sent the patient into the infirmary. On the next morning she was placed under chloroform, and as the ordinary instruments were much too short I took a piece of flexible wire covered with gutta percha three feet in length, doubled it, and made a small hook at the end at an angle of about 45°, and measuring the distance from the mouth to the upper part of the sternum, which was roughly 10 inches, I notched the wire at a distance of 12 inches from the hook, and passing it down to this extent "fished" for the halfpenny, and at the second "cast" caught it. It was very firmly wedged and there was considerable difficulty in drawing it up until I could touch it with my finger, when I held it in position, seized it with the œsophageal forceps, and removed it. On the next morning the little patient ate an excellent breakfast, and as the pain and cough had disappeared she was sent home. The severe cough was evidently caused by the pressure of the edge of the coin on the trachea.

Sunderland.

*** Dr. Squance sent with his note a radiograph which showed very clearly the coin lying at the level of the first or second dorsal vertebra.—ED. L.

### A CASE OF PRESUMED RUPTURE OF THE ANTERIOR ANNULAR LIGAMENT OF THE ANKLE-JOINT.

BY GEORGE W. ORD, M.R.C.S. ENG., L.R.C.P. LOND.

I WAS recently called to a case of so-called "sprained ankle." The patient, a muscular boy, aged 13 years, had twisted his right ankle when bowling at cricket. He did not fall down at the time but he was unable to walk. On examination half an hour later I found a slight amount of puffiness just internal to the external malleolus. There was no ecchymosis, but there was great pain on flexing the foot and on pressure over the swelling—in fact, far greater tenderness than would be expected from so slight a sprain. But for the fact that I knew the boy to be plucky and manly I might have diagnosed his apparent hyperæsthesia as a symptom of a neurotic temperament. Noticing impaired movements of the toes I made him stand up with both feet uncovered and then found the following condition. The big toe could be extended fairly well but not so well as its fellow on the sound limb; the second, third, and fourth toes could not be raised from the ground, though he was just able to communicate movement to them; while the little toe was immobile. I applied the battery to exclude the possibility of ruptured tendon and obtained muscular contraction of the extensor longus digitorum, but with diminished extension, especially of the little toe.

The injury seems to me to have been a rupture of the outer portion of the anterior annular ligament, the "giving way" of the fulcrum preventing the extensor tendons from doing their work. I can neither find nor hear of a record of a similar injury and I wonder that it does not occur more frequently. If anyone will take the trouble to put himself in the position of a right-hand fast bowler at the moment of delivering the ball he will notice the sudden jerk which the ligament in question will have to resist, the foot at the time being turned inwards. Of course, too, it follows that the faster the delivery is the greater the jerk.

The treatment in this case consisted of firm strapping and bandaging and after three weeks' rest limited extension was seen in the second, third, and fourth digits, but only slightly in the fifth. The patient then went to the seaside and on his return seven weeks after the injury (still wearing the strapping) I was pleased to find that extension of the toes was performed perfectly and was assured that he never had pain or discomfort during exercise. Running, however, had not been attempted. I told him that he must give up overhand bowling and had better practise "Jephson's lobs," an underhand yet fatal form of delivery.

The interest of the case lies, I think, in the rarity of such an injury and in the prognosis.

### ST. THOMAS'S HOSPITAL.

#### A CASE OF TYPHOID SEPTICÆMIA; NECROPSY.

(Under the care of Dr. H. G. TURNEY.)

A GIRL, aged 15 years, was admitted into St. Thomas's Hospital on Jan. 24th, 1900, and died on Feb. 2nd. The family history showed that a maternal grandmother and an uncle were treated in an asylum. The mother and the mother's two sisters suffered much from headache. There was nothing else in the history which pointed to inherited disease. The patient had had the ordinary diseases of childhood, but otherwise her health had been perfect. She was said to be of a nervous disposition. No history was obtained of exposure to infection of any sort. The catamenia were regular. There had never been any discharge from the ear. As regards the present illness, the patient complained of headache on Tuesday, Jan. 16th. This was rather troublesome on the following day, but on the Thursday evening she felt better and went to see a pantomime. On her return she complained of pain in the back and limbs and a medical man was consulted. She was then treated for anæmia and influenza. On the 20th she seemed to be worse; she slept very badly and had distressing dreams. On the 22nd she went to bed as usual, but the mother discovered in the night that she was rambling and unconscious. She had not recovered consciousness since. A friend stated that a fortnight ago the patient complained to her of pains in the

head and abdomen with occasional sweating and a feeling of faintness.

On admission the patient was a pale-faced girl in a state of complete unconsciousness. Her illness was described by the relatives as having begun with an "influenza cold" a week before with unconsciousness for the past two days. For the most part the girl lay without movement quite oblivious of her surroundings. She groaned occasionally and coughed now and then. Interference of the more active sort only, as when the mouth was forcibly opened, met with some resistance of a feeble kind. There was no stertor or puffing out of the cheeks with respiration. There was no obvious paralysis in any of the limbs; they did not fall back limply when dropped from a height, and occasionally they were moved voluntarily. The knee-jerks were present and were normal in degree. The plantar reflexes were obtained with extension of all the toes together and with dorsiflexion of the foot. There was on admission no loss of control over the sphincters. The conjunctival reflex was present and the pupils were of moderate size with retained reaction to light. The left pupil was generally a little larger than the right, though this was not always perceptible. There was no optic neuritis. The ears were normal. The lungs were normal save for the presence of numerous moist sounds which were especially audible at the bases. The respirations were 40. The cardiac apex was in the fifth space in the nipple line. Dulness commenced in the third space and was limited by the left sternal margin. No murmurs were heard. The pulse was 130, regular, and of fair volume. The tongue was very dry and was coated with brown fur. The lips and teeth were covered with sordes. The breath was very offensive. The abdomen was not distended or tender. It moved well with respiration. The spleen was not felt and the liver dulness was normal. There were no signs of fluid. A few rose-coloured papules fading on pressure were seen over the abdomen and the back. The urine was normal. The temperature on admission was 102·4° F.

On the day after admission the blood gave a doubtful Widal's reaction. With a 1 in 20 dilution there were clumping and loss of motility in 20 minutes; with a 1 in 50 dilution only a few loose irregular clumps were seen after half an hour. The urine gave a positive diazo reaction. The temperature was 104·4° in the morning and 104·2° in the evening. On the 26th the blood again gave a doubtful Widal reaction. The temperature was 104·8° in the morning and 105° in the evening. On the 27th the serum reaction was positive. With a 1 in 20 dilution there were clumping and loss of motility in five minutes and with a 1 in 50 dilution the same result occurred in a quarter of an hour. The temperature was 104·2° in the morning and 104·8° in the evening. On the 30th the Widal reaction with a 1 in 20 dilution was instantaneous. The temperature was 104° in the morning and 105·2° in the evening. On Feb. 1st the temperature was 104·8° in the morning and 108° in the evening. On Feb. 2nd it was 103·6° in the morning and 107° in the evening.

It is hardly necessary to give in detail the progress of the case for the nine days during which it was observed in hospital. The salient points were the following. As regards the state of the nervous system there was very little change from the state as described on admission. Unconsciousness persisted to the end, though during the last two days of life there were faint indications of a response to simple requests when made repeatedly. The evacuations were passed into the bed after the first day. At various times it was thought that some signs of local nerve disease had been detected—such as rigidity in one or the other upper extremity—but these signs proved to be of the most transient description and changed from day to day. There was no sign of pain, the patient lying quietly on her back. The only positive indication of enteric fever (apart from the Widal reaction) was the presence of what appeared to be typical typhoid spots on the trunk. These never amounted to more than five or six, but they were quite characteristic and developed in crops which faded in from 24 to 48 hours. None came out, however, after the third day from admission.

On Jan. 27th lumbar puncture was performed in three places between the second and third and third and fourth lumbar vertebræ, but not a drop of fluid was obtained, though there seemed to be no doubt that the needle entered the spinal theca. The bowels were kept open by means of enemata, the stools being in no way abnormal. Nasal feeding was necessary throughout the illness. Treatment was of course symptomatic and consisted mainly of antipyretic measures, tepid sponging in the earlier stage and cold water or ice packs in the later. Any good effects obtained were merely transitory. Besides this hypodermic injections of strychnia were administered and oxygen inhalations were repeated frequently during the last 24 hours of life.

*Diagnosis.*—In spite of the unusual features of the case the presence of the characteristic spots on the abdomen at once raised the question of typhoid fever, and this suspicion soon received confirmation from the positive result of Widal's test. The day before the patient's death still further confirmation was obtained by the admission into the hospital of a brother suffering from typical enteric fever and soon afterwards another member of the family came in with symptoms of the same disease. It was hoped that the lumbar puncture might have thrown light on the nervous symptoms which formed the dominant feature of the case clinically. It will be seen that the necropsy failed to explain why no fluid was obtained at any of the three attempts. An attempt to cultivate the bacilli from the urine also failed owing to the contamination of the specimen. The diagnosis was therefore not placed altogether above doubt till after death.

*Necropsy.*—The post-mortem examination was performed by Dr. C. R. Box 24 hours after death. The condition of the alimentary canal was perfectly normal from the fauces down to the rectum. Peyer's patches were not swollen or even hyperæmic, and there was no trace anywhere of ulceration. The solitary follicles were equally unaffected. The mesenteric glands were enlarged and succulent. The vermiform appendix was normal. The spleen was little above the average size, weighing less than six ounces, and was firm in texture. Under the usual precautions cultures were made from its pulp, the results of which are given in Dr. Jenner's report below. The liver and biliary passages showed no deviation from the normal. In the thoracic organs the only pathological changes visible were a marked enlargement of the bronchial glands and some collapse of the lower lobe of the right lung. The larynx was healthy and there was no sign whatever of old or recent tubercle. The nervous system showed no change. The cerebro-spinal fluid was quite limpid and normal in amount. There was the usual free communication between the cerebral and spinal divisions of the cavity, and no explanation was forthcoming as to why the repeated attempts to withdraw the fluid by puncture failed. One puncture mark was detected in the theca in the lumbar region. Various articulations were examined and found to be healthy.

*Bacteriological examination.*—The following is the report of Dr. Louis Jenner: "Six colonies were selected for investigation. Subcultures were made from these on to agar slopes. Subcultures were made again from these into melted gelatin. These were incubated at 22° C. Growth occurred in all, but there was no production of gas. One of the agar subcultures was selected for further investigation. Microscopically the growth showed a motile rod varying in length. This stained with the usual laboratory stains, but lost the colour by Gram's method. Subcultures were made on various media. On potato a colourless growth resulted. In sugar agar (glucose 2 per cent.) growth took place all along the line of puncture, but no gas was formed. On gelatin slopes a white transparent growth resulted resembling that of bacillus coli communis or bacillus typhosus. The colonies on gelatin were typical. On litmus agar there was a very slight production of acid followed by an alkaline reaction. In peptone water there was no formation of indol, as tested by Kitasato's method. In lactose broth there were no bubbles of gas. In cover-glass preparations stained to show them a larger number of flagella were seen on individual bacilli than ever occur on bacillus coli communis. The organism clumped readily in a dilution of 1 per cent. with serum from a known case of typhoid fever. The organism found is, therefore, bacillus typhosus."

*Remarks by* Dr. TURNEY.—It would be superfluous to insist upon the features, apart from the absence of intestinal lesions, which distinguish the above case from ordinary typhoid fever. But even among cases of typhoid fever without disease of the intestines it presents some features of interest. These cases, of which a fair number are now on record, may be divided into several groups. The first group includes those cases which after running a true clinical course as typhoid fever are found post mortem to lack the local lesion. In the second group, on the other hand, the

clinical course has been unusual and often absolutely unlike that of typhoid fever. The symptoms may be referable to the cerebro-spinal system in one case, to the biliary channels in another, and to the respiratory tract in yet another. Post mortem the findings correspond to the distribution of the symptoms during life; at one time they reveal a suppurative cerebro-spinal meningitis, at another an empyema, and at another a purulent infection of the bile-ducts, but in all cases alike the bacillus typhosus is found in more or less pure culture in the exudations. In the third group the symptoms during life and the findings after death correspond rather to what may be called a typhoid septicæmia—that is to say, to an intense poisoning with the organism but without any localised specific inflammation. To this last class the case just described appears to belong. The predominance of the nervous symptoms is not explained by the presence of any local infection and in all probability is due to an inherited neurotic temperament of which the family history gives strong indications. It is unfortunate that the blood was not examined for bacilli during life.

## SALFORD ROYAL HOSPITAL.

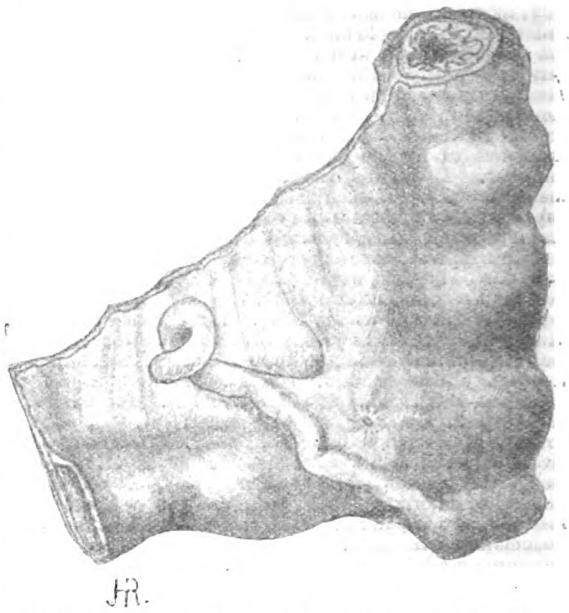
### FOUR CASES OF ACUTE ILEO-CÆCAL INTUSSUSCEPTION; TREATMENT BY LAPAROTOMY WITH REDUCTION OR EXCISION.

(Under the care of Mr. J. HOWSON RAY.)

THE value of primary laparotomy in intussusception is now widely acknowledged, and the results are very fair, though in many cases some days have been allowed to elapse before the patient is brought for treatment. When the operation is performed early the percentage of recoveries is high, but it is difficult to obtain exact statistics, as in so many cases inflation and injection have been attempted previously to operating. When some days have elapsed and adhesions have formed the mortality is much higher, especially if it be found necessary to resect a portion of the bowel. Intussusception is especially dangerous in very young children, as they are prone to suffer severely from shock. In all of the four cases recorded below the patient was under nine months old, and in the two cases which ended fatally the intussusception had existed for several days, and in one of them an enterectomy had to be performed. Within the last few years many cases of laparotomy for intussusception have been recorded, but still more records are required in order to determine the best methods of operating. It has not yet been shown whether it is desirable or not to suture the mesentery after reduction; it must certainly tend to prevent any return, but it prolongs the operation, though only very slightly.

CASE 1.—A strong, well-nourished child, aged eight months, was admitted to the Salford Royal Hospital on July 4th, 1899, with a history of two days' illness, having an acute onset, and marked by vomiting, the passage of blood and mucus per anum, severe abdominal pain causing the child to scream loudly and to draw up the legs, tenesmus, and shock. The abdomen was moderately distended, but it presented a loss of normal resistance over the right iliac fossa, whilst a "tumour" could be palpated extending from the middle line above the umbilicus to the left hypochondrium and then down the left flank to the region of the sigmoid flexure. A finger introduced into the anus at once encountered the apex of the intussusception, which readily came into view when the child strained. The child's condition permitted of no delay and a median laparotomy was performed, the incision extending from the umbilicus to the pubes. Through this incision, after squeezing the intussusception from the rectum and sigmoid to the descending colon, the "tumour" was protruded into hot damp towels, and reduction was rapidly effected to the last couple of inches, where the tucked-in appendix delayed the reduction considerably. After reduction a chromicised catgut suture was passed through the meso-appendix and the left or deep face of the ileo-colic mesentery, so as to draw these together, to excite some adhesion, and to render recurrence unlikely. The position of this suture is shown in Fig. 1, which represents the deep aspect of the ileo-colic union, the appendix, the meso-appendix, and the cæcum. The knot of the suture in Fig. 1 lies under cover of the meso-appendix. The abdomen was next flushed out with warm salt solution, and the abdominal incision was rapidly sutured with one row of silkworm-gut sutures. Dry dressings and strapping having been applied, with a body bandage over all, the child was put to bed, and he rallied fairly quickly from the operation. The temperature rose to 102° F. for two days after the operation and then it fell to normal and remained so throughout. The mother fed her

FIG. 1.



The ileo-cæcal junction and appendix viewed posteriorly and showing the meso-appendix, with loop of suture uniting this to the deep face of the ileo-colic mesentery. The ends of the suture lie under cover of the meso-appendix.

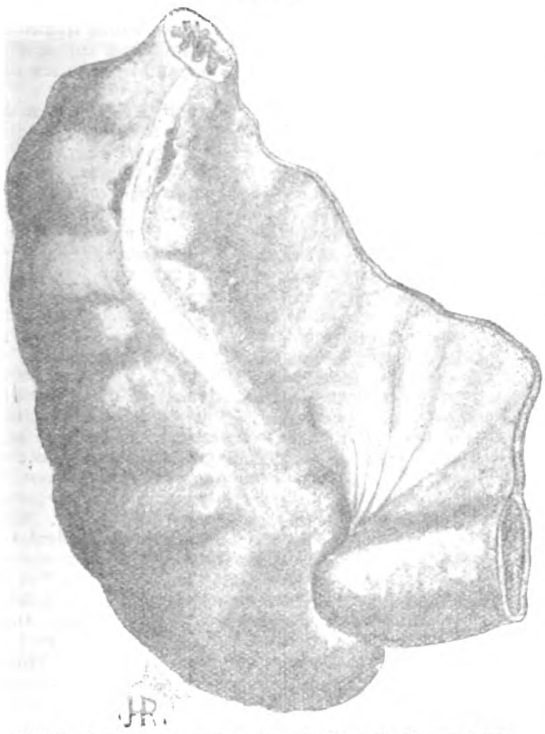
child from the breast by leaning over the cot so as to place the nipple to the infant's mouth, and she repeated this procedure every two and a half hours or three hours by day, and less often by night, for three weeks, when the child was quite well and was able to leave the hospital. (He has remained in good condition since.) The sutures were removed on the tenth day. The bowels acted on the first day after the operation and regularly afterwards. The child had no food beyond the mother's milk.

CASE 2.—The patient, a child, aged seven months, was admitted to the Salford Royal Hospital on July 7th, 1899, with a history of intussusception of 12 hours' duration, marked by sudden onset, with pain, and the discharge of blood and mucus per anum. The boy was puny and a "tumour" could be made out occupying the region of the transverse colon and extending to the left hypochondrium. There was also the *signe de Dance*. Shock, though present, was not pronounced, but an injection having failed to reduce the intussusception median laparotomy was carried out below the umbilicus, and by introducing a finger and thumb it was possible to express the "tumour" from the left hypochondrium to within the right iliac region. The last part of the intussusception was brought into the wound and with some difficulty the appendix was dislodged and reduction was effected. A catgut suture was passed through the meso-appendix and the ileo colic angle of the mesentery as in Case 1. About 18 inches from the cæcum a small double enteric intussusception was found. Here a segment of ileum, about one and a half inches long, contained short ascending and descending intussuscepta which were readily reduced. This enteric intussusception was secondary to the more serious lesion and the intestine at this point did not appear to be damaged or bruised. The abdominal incision was closed as in Case 1. Here also the mother fed the child from the breast soon after the operation and gave most of the nourishment taken in the first week. Later, as her supply was far from abundant, additional nourishment was given from the bottle with diluted cow's milk. The bowels were moved two days after the operation

and thenceforward with more or less regularity. The temperature rose after the operation to 100·2° F. and then fell, rising again on the third day to 103° owing to a superficial abscess. At the end of a week the temperature fell to normal and remained so. The sutures were removed on the tenth day and on the nineteenth day after the operation the child left the hospital soundly healed.

CASE 3.—The patient, a boy, aged seven weeks, was admitted to the hospital on Jan. 15th, 1900, with a history of acute obstruction for five days. The child was suffering from extreme shock, and the greatly distended abdomen permitted with difficulty the diagnosis of a tumour occupying part of the right iliac and lumbar regions. A little blood and mucus were passed per anum shortly after admission, but examination of the rectum revealed no other abnormality. Laparotomy was performed shortly after admission, and the greatly distended coils of small intestine prevented ready access to the intussusception. On opening the abdomen some purulent fluid, having a fæcal odour, escaped, and it was found that the ensheathing layer of the intussusception had given way on the anterior aspect on each side of the lateral band, and near the apex of the tumour (as shown in Fig. 2), setting up a diffused peritonitis. The intussusception was about four inches long and was irreducible. Resection was carried out, the small intestine was drained, and the ileum was anastomosed to the ascending colon by means of a small Murphy's button. The peritoneum having been flushed with warm salt solution and cleansed, the incision in the abdominal wall was rapidly closed by silkworm-gut sutures and the child was sent to bed. Shock was most profound and was never recovered from, death taking place nine hours after operation. An examination of the abdomen after death showed no leakage from the bowel or defect in the anastomosis and practically no free fluid in the peritoneum. The excised intussusception was found to have extensive recent adhesions between the middle and innermost layers.

FIG. 2.



Ileo-cæcal intussusception excised in Case 3. Shown from the anterior aspect. The rent in the ascending colon near the apex of the intussusception is bridged across by the lateral longitudinal band.

CASE 4.—A female infant, aged five months, was admitted to the hospital on June 15th, 1900, with a history of two and a half days' acute obstruction, the passage of blood and mucus per anum, and the presence of a tumour which was obscurely palpated in the lower umbilical and upper hypogastric regions at some distance from the surface. Examination per rectum revealed nothing but a little blood and mucus. The *signe de Dance* was well marked and there was severe peritonism. Laparotomy was performed half an hour after admission and the intussusception was found to occupy a deep position and to extend from the right pelvic brim nearly to the left hypochondrium. The small intestine having been retracted within the limits of the abdomen, the intussusception was reduced, but the last two inches gave very much trouble and required traction as well as expression to effect complete reduction. As the tucked-in appendix was extruded a depressed patch of doubtful vitality was noticed in the ascending colon, evidently due to the pressure of the appendix itself. The child's condition was bad, however, and it was decided to do nothing further except to suture the meso-appendix as in Case 1 and Case 2. The abdomen was rapidly closed as in the other cases. After the operation the temperature rose to 101° F.

TABLE GIVING PARTICULARS OF FOUR CASES OF ACUTE ILEO CÆCAL INTUSSUSCEPTION TREATED BY LAPAROTOMY WITH REDUCTION OR EXCISION.

| Date of admission to hospital. | Sex and age. | Character and extent of intussusception. | Duration of symptoms before admission. | Physical signs noted on admission. | Operation. | Anæsthetic. | Feeding. | Result. |
|---|---|---|---|---|---|---|---|---|
| July 4th, 1899. | M., 8 months. | Ileo-cæcal intussusception reaching to the anal canal. | Two days. | Blood and mucus per anum; vomiting and tenesmus; *signe de Dance*; tumour; shock. | Laparotomy and reduction. Suturing the meso-appendix to the mesentery. | Chloroform and ether. | Entirely by mother's breast. | Bowels acted on day of operation. Recovery. |
| July 7th, 1899. | M., 7 months. | Ileo-cæcal intussusception reaching to the splenic flexure; also a double enteric intussusception. | 12 hours. | Little blood per anum; no vomiting, and little tenesmus; *signe de Dance*; tumour; slight shock. | Laparotomy and reduction; fixation suture. | Chloroform. | Partly by mother's breast; also by bottle. | Bowels acted two days after operation. Recovery. |
| Jan. 15th, 1900. | M., 7 weeks. | Ileo-cæcal intussusception in right flank. Rupture of the colon. Peritonitis. | Five days. | Vomiting; blood per anum; "tumour" in the right flank, which was palpated with difficulty; extreme shock. | Laparotomy; excision of the intussusception; ileo-colic end-to-end anastomosis by Murphy's button. | Chloroform. | Diluted milk from teaspoon. | Death in nine hours. |
| June 15th, 1900. | F., 5 months. | Ileo-cæcal intussusception placed deeply towards the middle line and apparently three and a half inches long. | Two and a half days. | Vomiting; blood and mucus per anum; *signe de Dance*; severe peritonism. | Laparotomy and reduction; fixation suture. | Chloroform and A.C.E. | Four times from mother's breast. | Bowels acted in 14 hours. Death in 30 hours. |

and the child was restless, refusing all nourishment when first offered. About four hours after the operation the child was fed from the breast and subsequently on three occasions. About 14 hours after the operation the bowels were moved fairly well, a natural motion was passed, but the child failed rapidly about 24 hours after laparotomy and died from shock six hours later. Post mortem the peritoneum appeared to be quite normal, there was no recurrence of intussusception, and some adhesions had formed between the meso-appendix and the mesentery. There can be little doubt that earlier operation should have saved this patient.

*Remarks by* Mr. RAY.—The surgical treatment of acute intussusception presents many features of great interest and although the results of treatment by laparotomy and reduction, where this is possible, are not always so good as might be expected, failure is usually due to the fact that operation has been postponed until the involved portion of gut has been most seriously damaged, or that the initial shock and peritonism have caused too deep an impression to be removed by any treatment. In THE LANCET of Nov. 12th, 1898 (p. 1262), I reported a case of acute ileo-cæcal intussusception where laparotomy and reduction revealed a serious lesion in the ascending colon, and where death followed from continued shock in nine hours after operation. Since reporting that case the above cases of acute intussusception have been under my care, all being of the ileo-cæcal type. In three instances laparotomy and reduction were carried out and resulted in two recoveries and one death. In the remaining case the intussusception was irreducible, and, moreover, the ascending colon forming the intussuscipiens had perforated in two places; here the entire intussusception was excised and end-to-end anastomosis was performed by the use of Murphy's button, but this case terminated fatally. The duration of intussusception was 12 hours and two days respectively in the two successful cases, whilst it was two and a half days and five days respectively in the two fatal cases. The irreducible variety occurred in a child, aged seven weeks; the remaining children were aged eight months, seven months, and five months respectively and in each of these the mother fed the child from the breast after operation. In all four cases either a more or less definite tumour or the *signe de Dance* (loss of resistance to palpation over the right iliac fossa) could be made out and in all the cases an acute onset was speedily followed by the passage of blood and mucus per anum. It will be noticed that in three cases the patients were males and in one case the patient was a female. In the accompanying table will be found the leading features of each case.

## STATE HOSPITAL, JAMMU.

### TWO CASES OF RENAL SURGERY.

(Under the care of Lieutenant Colonel JOSHUA DUKE, I.M.S., Resident Surgeon in Kashmir.)

THE difficulty of detection of a renal calculus is often very great and needling has in many cases utterly failed to discover the presence of a stone which has been found later. The Roentgen rays are sometimes of value, especially when the stone is composed of calcium oxalate, for a uric acid stone gives but a very faint shadow. Probably the best procedure to adopt when palpation of the kidney gives no indication of the presence of a stone is to make an incision along the convexity of the kidney, laying open the cavity of its pelvis. In this way the whole of the organ can be very thoroughly explored and the stone can almost certainly be found.

CASE 1. *Nephrolithotomy.*—A sepoy in the Imperial Service troops, Kashmir, came before Lieutenant-Colonel Duke at an annual invaliding board in December, 1898. The patient then complained of severe pain in the right hypochondriac and lumbar regions. He said that this pain rendered his life a burden to him and that he could serve no longer as a soldier. Inquiry proved that he had previously undergone an operation at Gilgit for the relief of the pain and he showed a scar in the right loin. He was therefore admitted to hospital for further examination and operative treatment. A telegram was sent to the agency surgeon at Gilgit (400 miles distant) inquiring whether the man's statement was correct and a reply was received by wire saying that an operation had been performed—the kidney had been manipulated but no stone was found. Owing to the kindness of Major Roberts, I.M.S., Lieutenant-Colonel Duke is able to give the patient's previous history and a note on the primary operation.

The patient, who was 28 years of age, was admitted to the Military Hospital, Gilgit, on Jan. 23rd, 1899. He complained of pain in the right loin. Sometimes this pain was situated in the loin and at other times over the sacro-iliac joint, radiating to the other side. The urine contained albumin. As the case progressed the amount of albumin varied from one-eighth to one-sixth, sometimes almost disappearing. There was no blood. About the middle of April he began to have pain radiating from the loin into the right groin and testicle. As there was no improvement under treatment it was decided to explore the kidney on the supposition of stone, although the amount of albumin in the urine was not in favour of this.

An operation was performed on May 8th, 1899. The usual oblique incision was made in the right loin and the peritoneal fat was exposed. This was stripped off and the anterior surface and the hilum were fully exposed to the touch of the finger. The kidney was judged to be small and no prominence could be made out on any part. The posterior surface and ureter were also explored. It was not judged necessary to try the needle. Deep catgut sutures were placed in the muscles and a drainage-tube was inserted in the wound which healed without any complication. After the operation there was an interval without pain in the loin, but this symptom returned. The patient was sent back to Kashmir and Jammu, leaving Gilgit on June 16th, 1899.

On August 24th, at Jammu, the urine was of specific gravity 1026 and contained one-quarter albumin and lithates in abundance. He was re-admitted into the State Hospital, Jammu, on Dec. 26th, 1899. There was then severe and almost constant pain in the right hypochondriac region and in the right loin. The pain was aggravated by pressure before and behind. The urine was normal in every respect.

The second operation was performed on Jan. 1st, 1900. The right loin was opened for the second time. The incision was now made parallel with, but fully half an inch posterior to, the primary scar. The renal fat was exposed and some was torn out, and the kidney was brought well into view. Careful palpation revealed nothing. Needling was then commenced and six punctures were deeply made in various positions. Nothing could be felt and Lieutenant-Colonel Duke began to despair of finding anything. At the seventh puncture, however, made from below upwards a stone was felt and then struck on audibly. A deep incision was made and a Thompson's sound was passed. This at first entered the ureter, running easily; it was then withdrawn and turned and struck the stone in the upper calyx of the kidney with a metallic noise. The opening was then enlarged, free bleeding ensuing. The finger was now passed into the hilum on to the stone. The calculus, however, was firmly adherent and its pointed apex was imbedded, so that it had to be slowly peeled off and loosened. It was then removed with forceps. The hæmorrhage was controlled by sponge-pressure and after it had ceased a drainage-tube was inserted and the wound was firmly closed. The stone, which was roughly triangular in shape, weighed on removal 36 grains. The patient did well after the operation, though a good deal of blood was passed in the urine, a symptom which continued until the ninth day. On Jan. 15th the drainage-tube, which had been frequently shortened, was taken out and the sutures were removed. There was slight sweet discharge. The urine contained mucus and lithates but no blood or pus. On Feb. 1st the wound was soundly healed and the patient was up and about.

CASE 2. *Nephrotomy.*—A Hindu male, aged 35 years, was admitted into the State Hospital, Jammu, on March 16th, 1900. Ten years ago he had an acute attack of pain in the left lumbar region which lasted for 12 hours and was relieved by taking a warm drink, prescribed by a native physician. The pain was associated with a sensation of something rough passing down from the kidney and the patient thought that his left testicle was drawn up. Three years later he passed some sand and gravel with his urine. Four years subsequently he had another attack of lumbar pain similar to the first. There was no history of hæmaturia or definite pain with drawing up of the testicle. He had never had retention of the urine. His general health had failed since these attacks. On admission there was marked tenderness on pressure over the lower border of the right kidney below the rib, the patient wincing when the thumb was pressed on.

The pain was increased when the hand was placed over the abdomen and pressure was made from behind. He complained of a sensation of something rough moving in the region of the kidney. The above were the only symptoms. The urine was of specific gravity 1029 and was healthy in every way.

An operation was performed on March 21st, 1900. The kidney was exposed in the left lumbar region by an incision four inches in length. About two inches of perirenal fat were removed and the kidney was brought into view, but not outside the loin. On drawing the lower end of the kidney into the wound a small cyst of the size of a pea was seen. This was needled and a little yellow serum was evacuated. On passing the needle in deeper some more of the same serum (almost pus) oozed up. The needle was then passed in deeply at the lower fourth and struck on what felt exactly like a stone or concretion. A cataract knife was passed down over the needle, which was withdrawn, but no stone was felt, although the needle had given the actual sensation of hitting a stone. A free incision was then made in the lower part of the organ and the finger was passed in but nothing could be felt. A sound was then inserted which, however, did not pass down the ureter owing probably to the incision being in the lower third of the organ. The finger was then thrust on the hilum. All the calyces were explored but no stone could be felt with the finger inside and careful palpation outside. Several small nodules or lumps were felt; all these were needled. They were probably small cysts of the same nature as that seen on the surface. The operation had therefore unwillingly to be abandoned, although the operator could have sworn that a stone or concretion had been originally struck on. It may be noted that while exploring with the finger inside the respiration twice stopped. The hæmorrhage in this case was very trifling. A drainage tube having been inserted, the deeper structures were drawn together by catgut sutures and the wound was firmly closed by six silk sutures. One-third of a grain of morphia was injected after the operation, as the kidney had been severely handled.

On March 22nd the patient passed a restless night. The dressings, which were soaked with bloody serum, were changed. The temperature was 102° F. The patient had a cough and there was viscid white expectoration pointing to pneumonia. On the 23rd the temperature was normal, the pain was much less, and the general condition was satisfactory. On the 24th he was doing well. On the 27th the urine was still smoky. There was a discharge from the wound with a uriniferous smell. The cough was still present, with frothy expectoration; the respiratory sounds were clear over both lungs. On April 3rd and 4th there was a rise of temperature in the evening. On the 5th the dressings were still soaked with a uriniferous discharge. The lower two-thirds of the wound had healed but there was no attempt at union in the upper third, which was a fistulous track four inches deep. The urine was now quite clear. There was an erysipelatous blush around the wound and the interscapular region. The patient was removed to a separate room, the ward in which he had been treated being rather overcrowded and occupied by some very foul cases, including famine-stricken patients with sloughing ulcers. To continue briefly, the patient was brought to death's door by this and subsequent erysipelatous attacks from which recovery was slow, and he was not discharged from the hospital until June 3rd. The wound had then completely healed, the process of union being retarded by consecutive attacks of erysipelas. There had been no recurrence of pain in the loin ever since the operation and the deep-seated tenderness over the kidney was no longer complained of.

*Remarks by* Lieutenant-Colonel DUKE.—Considering the enormous preponderance of cases of stone in the bladder in India and the extensive removal of calculi by litholapaxy, it is curious that stone in the kidney is comparatively rarely met with, and surgeons in India do not appear to have the opportunities of exploring the kidney that fall to their *confrères* at home. When Mr. Henry Morris, the great pioneer and exponent of kidney surgery in England, was house surgeon at Guy's Hospital I had the honour of being dresser at that institution; but during my period of studentship I cannot recall seeing a kidney cut down on, nor, unfortunately, have I ever seen this operation performed by a skilled surgeon. In Indian civil and hospital practice, however, one has to take every case that comes to hand. As bearing on this subject since my case in 1895 of nephrotomy for neuralgia of the kidney,[1] though I have performed litholapaxy many times the above two cases are the only ones that have occurred in my practice. The points of interest in Case 1 are (1) the presence of a large though transient quantity of albumin, and (2) the fact that simple manipulation failed to discover the presence of a calculus. In Case 2 the operation only revealed cystic disease of the kidney. No stone was found although the kidney was most freely handled and examined. It is just possible that a small stone was pushed on or slipped into the ureter, which was not carefully catheterised.

# Reviews and Notices of Books.

*Manual of Midwifery.* By W. E. FOTHERGILL, M.A., M.D. Edin. Second edition. With double Coloured Plate and 76 Illustrations in the text. Edinburgh: W. F. Clay. 1900. Pp. 506. 8vo. Price 9*s.* net.

WE are glad to see by the appearance of a second edition that this very excellent little manual has met with some success. Owing to the short time that has elapsed since its first appearance very little alteration has been required to bring it up to date. The author has succeeded in doing this without materially adding to its size, the increase in the number of pages being only about 20. Amongst the additions we notice a short account of Van Tussenbroek's case of ovarian pregnancy. The section devoted to the subject of posture during labour has been largely added to and diagrams have been introduced to show the advantages derived from an adoption of Walcher's position. Dr. Fothergill arrives at the following conclusions with regard to the position of the patient: 1. For labour presenting no difficulty the left lateral posture is best. 2. If the head be arrested at the brim Walcher's posture, legs hanging down. 3. Head arrested at the outlet of the long pelvis, lithotomy posture, legs pressed against the abdomen. 4. Head arrested on the perineum, legs extended at the hips.

In a short account of the organisms most commonly met with in cases of puerperal infection too much is, perhaps, said about the bacillus coli communis. It has yet to be proved with certainty that either the staphylococcus or the bacillus coli communis can give rise to septic infection as opposed to septic intoxication. With the statement that most cases of "fever during the puerperium are not cases of puerperal septicæmia" but are due to the absorption of poisonous substances from the alimentary canal we entirely agree.

In an appendix Dr. Fothergill gives a short account of the so-called hepatic toxæmia of pregnancy. Its relation to the minor and major disorders of pregnancy and its proper treatment are fully discussed.

Several new figures have been added, including the microscopic appearances of the decidua and villi and illustrations of fleshy moles. We would like to suggest to the author that in place of Fig. 9—an inaccurate diagram of the placenta—he should insert in another edition either a new and accurate diagram or one of the very excellent drawings of the placenta to be found in Varnier's "Obstétrique Journalière." The book contains a clear and good account of the facts of midwifery and is well worth reading.

*Essentials of Diagnosis.* By SOLOMON SOLIS-COHEN, M.D., and AUGUSTUS A. ESHNER, M.D. Second edition, revised and enlarged. Illustrated. London: Henry Kimpton. 1900. Pp. 391.

THE first edition of this little work, published in America in 1892, constituted one of the series known as Saunders's Question-compends. Its popularity among medical students in America to-day justifies a second edition and warrants its inclusion in Kimpton's Students' Series. In its present form

[1] Vide THE LANCET, August 17th, 1895, p. 407.

it enters into competition on even terms with our own Aid Series and such students' digests as are intended to assist in the rapid preparation for medical examinations. The new edition is enlarged, revised, and brought up to date. As regards the new subject matter that which deals with those interesting and obscure diseases, or symptoms, known respectively as acromegaly and pulmonary hypertrophic osteo-arthropathy, appears most complete and suitably illustrated.

The method adopted in "Essentials of Diagnosis"—namely, that of question and answer—certainly renders its highly condensed pages lighter and more interesting reading than a mere abstract covering the same ground. It conduces, however, to a style of expression which is dogmatic and not always justifiable even in the formulation of definitions intended solely for consumption by students. For instance, the differential diagnosis between rheumatism and gout and between hæmatemesis and hæmoptysis must strike the reader as singularly inadequate and impracticable. And when the student learns from his "essentials" that measles are only liable to be confounded with typhus fever he may well ask himself whether the conditions of disease in this country and in America are sufficiently identical to justify the adoption of a common guide to diagnosis. The definition of rachitis as a disease practically confined to the perverted development of bone in growing children is hardly one which we should expect to learn from America, the Mecca of pediatrics.

The *lapsus calami* of "chordæ tendinea," an excusable error in a first edition, jars rather unpleasantly when perpetuated in a second and "thoroughly revised version." As a cram book for English students "Essentials of Diagnosis" must stand or fall by its own merits, but we would once again warn students against adopting such books in place of the recognised text-books. A "cram-book" may be employed to *test* a student's knowledge but should never be used to *acquire* that knowledge. Students, moreover, will be well advised to recognise that the nomenclature and orthography of American authors are not always in harmony with English ideas and usages.

---

*Lehmann's Medicinische Handatlanten. Band VII.: Atlas und Grundriss der Ophthalmoscopie und Ophthalmoscopische Diagnostik.* Mit 149 farbigen und 7 schwarzen Abbildungen. Von Professor Dr. O. HAAB in Zürich. Dritte stark vermehrte Auflage. (*Lehmann's Medical Hand-Atlases. Vol. VII.: Atlas and Elements of Ophthalmoscopy and Ophthalmoscopic Diagnosis.* With 156 Illustrations (149 coloured). By Professor HAAB of Zürich. Third edition, considerably enlarged). Munich: Lehmann. 1900. Price 10*s.*

THIS volume is one of 30 illustrated manuals published by M. Lehmann, written by specialists and intended to assist students in their studies. Other volumes deal with gynæcological operations, with normal and with pathological histology, with operative surgery, cutaneous diseases, bacteriology, and other branches of medicine. The chromolithographs are very fair representations of the principal forms of disease likely to be met with in practice, and this edition has been considerably enlarged, not only by the introduction of new plates of the fundus oculi in disease, but by others which display the appearances presented in microscopical sections. Thus Fig. 15 shows a section through the optic nerve and disc in a case of papillitis or stauungspapille; Fig. 21 a section through the optic nerve in a case of atrophy of the nerve; Fig. 24 a section of the normal globe close to the margin of the cornea, whilst others exhibit the structures in the vicinity of the ciliary region, as well as the appearances presented by the excavated optic nerve papilla in glaucoma; and Fig. 27 illustrates the retina in Bright's disease. The new coloured drawings of the fundus include one showing air-bubbles in the vitreous after injury, others show retinal arterial disease in syphilis, detachment of the retina at an early stage of its development, senile pigmentation of the retina, and atrophy with the formation of holes in the retina near the macula lutea. There is a short introductory essay of 82 pages on Ophthalmoscopy generally, and a brief but intelligible explanatory note giving an account of the peculiar features accompanies each drawing. The price of this useful volume is remarkably moderate considering the number of coloured plates it contains and the care with which they are drawn, and the student and general practitioner will alike find it a useful help in the diagnosis of ophthalmic disease.

---

*Troubles Mentaux de l'Enfance. Précis de Psychiâtrie Infantile.* (*Mental Troubles of Childhood.*) By Dr. MARCEL MANHEIMER. Paris: Société des Éditions Scientifiques. 1899. Crown 8vo. Pp. 188. Price 4 francs.

A SPECIAL study of these diseases on the part of general practitioners is desirable partly because the effects of disturbances, organic or functional, on the child's brain differ from those produced by similar causes on the adult organ, but mainly because in education we have a remedial agent the value of which is unknown to, or underrated by, many of those who are in charge of mentally deficient children. Though no amount of training will remove an organic lesion or altogether repair the faults of heredity, yet, as Professor Joffroy says in his introduction to Dr. Manheimer's book, a properly directed education constitutes the best prophylaxis against insanity in the case of children hereditarily disposed to it. This little book epitomises in plain language, for the benefit of teachers and practitioners, the views held by most alienists on the subject of the mental diseases of childhood. While his object is a laudable one it is doubtful if the author gets far on his way to achieve it. He succumbs too often to the besetting sin of the *précis* writer and gives us a catalogue instead of an epitome. The reader who has studied larger works and is familiar with the subject to some extent will find this volume useful as a convenient way of refreshing his memory, but we fear that it will prove somewhat too concentrated a food for the digestive powers of a beginner. The book is divided into five parts. The first discusses shortly the etiology of mental affections. Here heredity plays an all-important rôle; it is, as the author puts it, "the cause of causes." Whether one parent exercises a greater influence on the child than the other has not been determined yet, but it is certain that where both parents are mentally affected or are alcoholic the chances of the child escaping some hereditary taint are small. Part II. deals with disturbances of emotion, intelligence, and consciousness. In the third part the author touches on pure psychoses, mental degeneration, neuroses such as epilepsy, &c. The medico-legal aspect of the subject occupies Part IV. French law, we are told, does not recognise full civil responsibility till the age of 21 years is reached. Full criminal responsibility is attained at 16 years of age. Below that age the accused is presumed to be innocent, although culpability may be proved. In the case of infants who are mentally deficient the degree of responsibility appears to be estimated by the general condition of the individual. In Part V. the author leaves himself but little space for his views on treatment except as regards "suggestion." He is of opinion, rightly as we think, that recourse should be had to hypnotic suggestion but rarely and only where other methods are unsuccessful—e.g., in cases of obsession by ideas of terror or anxiety. In most other cases general treatment, with or without "simple suggestion," will be found sufficient.

The book is written very lucidly and it conveniently

summarises the more important points in our knowledge of this interesting subject.

---

*Grundriss der Klinischen Bakteriologie.* (*Outlines of Clinical Bacteriology.*) By Dr. E. LEVY and Dr. F. KLEMPERER. Second edition, improved and enlarged. Berlin: A. Hirschwald. 1898. Medium broad 8vo. Pp. 450. Price 10 marks.

THIS book is intended primarily for students and practitioners. It regards the subject of bacteriology from the point of view of clinical medicine and therefore only those bacteria which are associated with the diseases to which human beings are liable are described in the text. An appendix gives a short account of some of the bacteria commonly found in earth, air, and water and ends with a chapter on Disinfection. The authors have divided their work into four parts. The first deals with the morphology and biology of bacteria in general, with immunity and infection, and with the different methods of culture and investigation; the second with the pyogenic and inflammatory bacteria; the third with the diseases caused by specific bacteria; and the fourth with infection by hypho- and blasto-mycetes and animal organisms such as the parasite of malaria, &c.

The first part is the best in the book. The chapters on Infection and Immunity give a lucid description of a difficult subject, while the section on the preparation of culture media and staining reagents is detailed and accurate. In the rest of the book the authors are somewhat hampered by the difficulty of treating a large matter shortly, and sometimes in the effort to make things plain for the beginner they yield to the classifier's peculiar temptation and indicate as distinct boundaries which are at present ill-defined—e.g., in the matter of croupous and broncho-pneumonias. The difficulty, again, of determining in a hospital whether a case of nasal discharge or sore-throat in which the Klebs-Loeffler bacillus has been found is to be regarded as one of diphtheria or not is often much greater than the book would lead the student to suppose. We have become so accustomed nowadays to associate malaria with mosquitoes that it is curious to find a writer only two years ago saying that "the conveyance [of malaria] by insects is theoretically possible and is even assumed by certain authors, but has not been demonstrated yet."

The authors have compressed a great deal of information into a little space, and their book forms an admirable introduction to the study of clinical bacteriology.

*An Introduction to Pathology and Morbid Anatomy.* By T. HENRY GREEN, M.D., F.R.C.P. Lond., Physician and Special Lecturer on Clinical Medicine at Charing-cross Hospital and Senior Physician to the Hospital for Consumption and Diseases of the Chest, Brompton. Ninth edition, revised and enlarged by H. MONTAGUE MURRAY, M.D., F.R.C.P. Lond., Physician to Out-patients and Lecturer on Pathology and Morbid Anatomy at Charing-cross Hospital. With Coloured Plate and 337 Illustrations. London: Henry Renshaw. 1900. Pp. 596. Price 21*s.*

A REVIEW of a ninth edition of such a well-known text-book as that of Dr. T. Henry Green's "Introduction to Pathology and Morbid Anatomy" needs no remarks as to the general scope and nature of the work. Dr. Montague Murray, who has ably edited the new edition, informs us in the preface that nearly half of the subject matter has been re-written and that several new sections have been added. The introduction of no less than 180 new illustrations has resulted in some increase in the size of the book; most of these have been drawn by Mr. Collings from photographs. The artist, the editor, and the original author of the book may all be congratulated on the result. The details of the various illustrations are most clearly portrayed and beautifully reproduced.

In a large book of this nature it is difficult to select any particular portion for criticism. The chapter on Tumours occupies 72 pages and will be found to contain an immense amount of information. The principal theories which have been advanced as regards the etiology of morbid growths are carefully discussed, but it is admitted that nothing certain is at present known. The various hypotheses that have been propounded appear to embody at least portions of the truth; they point to subordinate causes which are at work in individual instances and which need a central principle to unite them into a coherent whole. Perhaps by the time the next edition of this work appears some of the institutions or observers who are conducting investigations on the causes of "cancer" will have issued their reports and some more definite knowledge will have been arrived at.

Another interesting chapter is that on Disturbances of the Circulation, and we would especially draw attention to the sections on Thrombosis and Embolism. The causation and characters of these pathological conditions are very well described. All the latest knowledge obtained by experimental research appears to have been incorporated. The pathology of infarction is somewhat obscure. In connexion with this subject the investigations of Mall and Welch as to red infarction are noted. These observers ligatured all the vascular communications of the intestine, with the exception of the main artery and vein, and then tied the bowel above and below so that the included portion was supplied by the main artery and the blood returned by the main vein. Under these circumstances no infarction resulted. They then gradually constricted the main artery, and found that when it was sufficiently compressed to stop the lateral pulsations in its branches—or, in other words, to reduce the pressure in them to about one-fifth of the normal—hæmorrhagic infarction appeared, thus proving that the diapedesis of the red corpuscles depends on marked slowing of the arterial current, by which all distinction between the axial and peri-axial streams is lost, combined with marked increase in the capillary and venous pressure. The red corpuscles are thus brought into contact with the capillary walls and possibly pass along with the lymph between the endothelial cells.

The pathology of the nervous system is so complex and so many advances have recently been made as regards its structure and functions that it has been almost impossible for anyone, except those constantly engaged in neurological studies, to keep pace with the original observations now so frequently recorded. Dr. Murray, therefore, was fortunate in securing Dr. F. W. Mott to write the chapter on the Pathology of the Nervous System. The morphology of the nervous system is first fully described and then the various morbid conditions are described *seriatim*. The section on Degeneration and Regeneration is well worthy of study, and the account of the effects of degeneration upon function is a triumph of minute and exact description. The illustrations in this chapter are excellent, many of them being borrowed from the Archives of Neurology of the London County Council.

Dr. Green's book will continue to take a first place amongst the text-books of pathology and Dr. Murray has brought the present edition fully up to date in every respect.

---

*Agricultural Botany, Theoretical and Practical.* By JOHN PERCIVAL, M.A. Cantab., F.L.S., Professor of Botany at the South-Eastern Agricultural College, Wye. London: Duckworth and Co. 1900. Pp. xii.-798. Price 7*s.* 6*d.*

"ALTHOUGH the book has been primarily written for the benefit of students of agriculture, the greater portion of it

is equally well adapted to meet the requirements of gardeners and all who desire to obtain an insight into the general structure and life-processes of plants." So writes Professor Percival in his preface. We should like to go a step further and say that students of pure botany would do well to read this work, for in it will be found much information which they should possess. This is the more desirable, since many students of botany are strangely ignorant of the agricultural aspects of their subject, although the fault is not wholly theirs.

The first three parts constitute what is practically an elementary text-book of botany, the morphology, anatomy, and physiology of plants being considered. One of the chief difficulties in writing this portion of the work was, we imagine, in deciding what was necessary for the readers for whom the work is primarily intended. The author has succeeded on the whole in writing sufficient; no unnecessary details are to be found. On the other hand, there are a few points which might have been included and some facts which might have been described a little more fully. For example, on p. 18 the perisperm is not mentioned in the section dealing with the food stores of the seed. Again, on p. 141 the characteristics of the endodermis of the root might have been more fully described and less diagrammatically figured; also no mention is made of the exodermis, a layer characteristic of many roots. In the portion dealing with the embryo-sac the number of antipodal cells in this structure is given as three; this is not the case invariably. Directly following is an account of fertilisation, but no mention is made of the recent and important work of Nawaschin, Guignard, and Miss Thomas on the fertilisation of the endosperm nucleus in certain Dicotyledons and Monocotyledons. These and similar unmentioned points are not, however, vital ones, and it is perhaps only a matter of opinion as to whether they should be included or not.

On page 237 is an account of intra-molecular respiration. As Professor Reynolds Green remarks in a recent work, "The term is rather an unfortunate one, for as we have seen the study of the ordinary respiratory processes has shown that the molecule of the living substance is the seat of the changes they involve, and hence that all respiration is intra-molecular." The term "anaerobic respiration" is a much better one and is to be recommended.

It is pleasurable to see Professor Percival using the terms "wind-pollinated" and "insect-pollinated," for, as he very truly remarks, there is a certain amount of looseness in describing a plant as being insect-*fertilised* when it is intended to state that the organism is *pollinated* by insects.

Parts IV.—VI. are devoted chiefly to purely agricultural botany. They enter into the consideration of the chief plants grown on a farm, describing them and their varieties, besides entering into various facts the knowledge of which is more or less essential to their successful cultivation. The common farm weeds are also described as are the methods to be used in exterminating them.

Part VI. consists of a very valuable account of farm seeds. The remaining portions of the work are occupied by an account of the fungi, considered chiefly in relation to some common diseases of plants, and the morphology, physiology, and the reproduction of the bacteria.

The arrangement of the book leaves nothing to be desired. The method of intercalating experimental work throughout the text is an excellent one. Practical work is all-essential; and the exercises and experiments given, all of which may be easily carried out, will not fail to make the student thoroughly understand the principles and facts laid down. The illustrations, of which there are 265, are, with very few exceptions, really excellent.

Sufficient has been said to show that this work is extremely good; when properly used it will give the reader a correct and valuable insight into agricultural botany. The author is to be congratulated upon its publication.

## LIBRARY TABLE.

*The Pocket Formulary for the Treatment of Disease in Children.* By LUDWIG FREYBERGER, M.D. Vienna, M.R.C.P. Lond., Clinical Assistant, Hospital for Sick Children, Great Ormond-street; Curator of the Museum, Pathologist and Registrar, Great Northern Central Hospital. Second revised and enlarged edition. London: Rebman, Limited. 1900. Pp. 239. Price 7*s.* 6*d.*—The fact that a second edition of this little volume was called for in less than 18 months after the first publication of the book is sufficient to show that the efforts of the author have been rewarded and that there was a need for such a publication. The new British Pharmacopœia caused so many alterations in the nomenclature and composition of the various officinal preparations included in it that the "Formulary" had nearly to be re-written throughout, so that we have practically to deal with a new book. Numerous additions have been made and recipes for medicated baths have been included in the appendix. The book is conveniently arranged for purposes of reference. The drugs have been placed in alphabetical order. The text devoted to the consideration of the drugs gives successively a brief account of their properties, use, therapeutics, incompatibles, dose, correction of their taste, examples of formulæ, their antagonists and antidotes—in short, a large amount of information is given in a minimum of space. The greater number of the drugs and pharmaceutical preparations considered are included in the British Pharmacopœia. In addition will be found a considerable number of drugs which are not officinal, but which are more or less frequently employed in this country for the treatment of diseases of children. Special attention has been paid to the correction of the taste of the drugs; the minimum quantity of the flavouring agent which suffices to disguise the disagreeable taste or smell of a given drug has been fixed by experiment. At the end of the book is a therapeutic index which contains the names of the most common diseases of childhood and of the drugs which are best suited for their treatment. It also gives lists of the various classes of drugs, antipyretics, carminatives, emetics, expectorants, &c. The author has spared no pains to make his work as complete as possible and the busy practitioner will find in it most valuable aids in the treatment of his little patients. To those whose practice involves the care of a large number of children we can cordially recommend Dr. Freyberger's "Formulary."

## JOURNALS.

*Birmingham Medical Review.*—One of the original articles in the September number is a description by Dr. W. A. Potts of a case of Extreme Anasarca Complicating Pregnancy and Labour. The patient was a primipara, 32 years of age. In the ninth month of pregnancy she was "able to get about, but only with great difficulty; she suffered severe pain in the legs and thighs, which were so swollen while the skin was so coarse and dry that they suggested to the touch the trunks of trees." Labour commenced spontaneously and after it had continued for four days twins were extracted under chloroform by drawing down the feet; they were both in a condition of white asphyxia, but were resuscitated. Three days later the œdema was almost gone; the woman, however, kept her bed for a little more than a month.

*Dublin Journal of Medical Science.*—The original articles in the September number are as follows: Maternal Mortality in Childbed, by Dr. W. J. Smyly; the Teaching of Materia

Medica, by Dr. W. G. Smith; Portrush from a Medical Point of View, by Dr. J. C. Martin; and the Accentuation of the Second Sound in the Pulmonary Area, by Dr. J. F. O'Carroll.

*Mercy and Truth.*—In the September number Mr. Arthur Neve writes on Surgery (chiefly eye operations) at Mission Stations in the Punjab and Mr. Arthur E. Clayton describes his hospital and dispensary work at Onitsha in West Africa.

*Gazette Médicale d'Orient.*—This fortnightly periodical, published in French, is the journal of the Imperial Medical Society of Constantinople. The number dated Sept. 1st possesses features of exceptional interest, its 60 pages being devoted to an address delivered by Dr. B. Ritzo at an extraordinary meeting of the society held on August 31st. The occasion was the twenty-fifth anniversary of the accession of the present Sultan, and Dr. Ritzo, who is a member of the editorial staff of the *Gazette*, took for his theme the medical and hygienic work accomplished under that ruler (L'Œuvre Médicale et Hygiénique de S.M.I. le Sultan Abd-ul-Hamid Khan II., 1876 1900). The address, which must have occupied more than two hours in delivery, is full of information compactly arranged, and, representing as it does a pleasing chapter in the modern history of Turkey, it deserves to be known to writers on the affairs of that country and to those who are interested in the spread of medical education and in questions affecting hospitals. Dr. Ritzo pays a loyal tribute to the work of the Imperial Medical Society, which, as he mentions, was founded in 1854 and has a monthly grant of 5000 piastres (£45 3s.). Among the numerous military hospitals he first directs attention to the Ambulances Militaires de Yildiz, which were commenced in 1892 and now consist of 13 pavilions—three for the staff and stores and 10 for the patients, of whom at least 200 can be accommodated. The whole of the buildings, furniture, &c., were ordered in Germany. Among the civilian hospitals most space is devoted to the Hôpital Hasséki for Women, the Hôpital Hamidié for Children, the Lunatic Asylum at Top-Tachi, the Greek, Armenian-Gregorian, and French Hospitals, and the Institute for the Care of Foundlings originated and superintended by Dr. Zavitziano. A somewhat brief reference is made to the British hospitals in Constantinople, Smyrna, Jerusalem, and Jaffa. Dr. Ritzo ascribes all medical and sanitary progress in Turkey to the direct initiative of the Sultan, and on almost every page alludes to him with an Oriental fervour of admiration which is seldom if ever met with in Western writings and may be estimated from the concluding words of the address: "J'ai donc hâte de finir, afin de laisser libre cours à l'épanchement de votre cœur, qui ne peut plus se retenir de crier: Gloire à notre Auguste Souverain le Sultan Abd-ul-Hamid Khan II., le Ghazi,

"Gloire! Gloire! Gloire!"

PAUPERISM IN BARNSTAPLE.—At the meeting of the Barnstaple Board of Guardians held on Sept. 21st the Local Government Board inspector (Mr. Preston Thomas) stated that in the Barnstaple Union the pauperism was 44 per 1000, as compared with 25 per 1000 of the population generally.

LITERARY INTELLIGENCE.—Mr. Young J. Pentland will publish the following books in the autumn:—"Text-book of Physiology by British Teachers," edited by E. A. Schäfer, Professor of Physiology in the University of Edinburgh, volume II., completing the work; "Text book of Medicine by British Teachers," edited by G. A. Gibson, M.D. Edin., physician to the Royal Infirmary and Lecturer on the Principles and Practice of Medicine at the School of Medicine, Edinburgh; "Text-book of Pharmacology and Therapeutics," edited by W. Hale White, M.D., F.R.C.P. Lond., physician and Lecturer on Medicine, Guy's Hospital; "Gynæcological Operations," by Skene Keith, F.R.C.S. Edin.; and "Diseases of the Throat, Nose and Ear," by P. McBride, M.D. Edin., physician to the Ear and Throat Department, Royal Infirmary, Edinburgh.

# Analytical Records

FROM

# THE LANCET LABORATORY.

## AUSTRALIAN WINES.

(P. B. BURGOYNE AND CO., 5, DOWGATE-HILL, LONDON, E.C.)

WE have examined a number of wines submitted to us by the above firm and the following are the results of analysis. Harvest Burgundy (red): extractives, 3·15 per cent.; mineral matter, 0·32 per cent.; fixed acids reckoned as tartaric acid, 0·277 per cent.; volatile acidity reckoned as acetic acid, 0·14 per cent.; alcohol, by weight 12·85 per cent., by volume 15·86 per cent., equal to proof spirit 27·81 per cent. Harvest Burgundy (white): extractives, 1·66 per cent.; mineral matter, 0·17 per cent.; fixed acids reckoned as tartaric acid, 0·375 per cent.; volatile acids reckoned as acetic acid, 0·132 per cent.; alcohol, by weight 11·46 per cent., by volume 14·18 per cent., equal to proof spirit 24·85 per cent. Ophir red wine: extractives, 5·53 per cent.; mineral matter, 0·41 per cent.; fixed acids reckoned as tartaric acid, 0·30 per cent.; volatile acids reckoned as acetic acid, 0·096 per cent.; alcohol, by weight 13·69 per cent., by volume 16·89 per cent., equal to proof spirit 29·60 per cent. Tintara (red): extractives, 3·28 per cent.; mineral matter, 0·28 per cent.; fixed acids reckoned as tartaric acid, 0·345 per cent.; volatile acids calculated as acetic acid, 0·15 per cent.; alcohol, by weight 12·46 per cent., by volume 15·40 per cent., equal to proof spirit 26·99 per cent. There is not much variation in the foregoing figures, except in the case of the white Burgundy. The harvest red Burgundy, Ophir, and Tintara wines are decidedly heavy in character and for consumption better diluted with water. Apart from the high proportion of spirit these contain also a somewhat large amount of extractive matters. The wines, in fact, are somewhat crude in character; they do not possess delicacy. The amount of spirit considerably exceeds the normal amount in the corresponding French wines. It is possible that spirit is added as a necessity for keeping the wine in sound condition during transport. The amount exceeds, at any rate, the maximum contained as a normal product of fermentation in French wines. We consider the white Burgundy more promising than the rest. It is in general lighter in character, containing a small quantity of extractives and relatively a small quantity of spirit. It approaches nearer to the delicacy of French wines than do the other specimens. We do not doubt that the quality of these colonial wines will improve in time in the important respects of delicacy of flavour and lightness of alcoholic strength. At present they are too "generous" and "rough." It is claimed that the Ophir and Tintara wines being grown on ferruginous soil take up a notable quantity of iron. We do not regard the quantity of iron so taken up as at all important. Iron occurs in nearly all wines in much the same amount, which is generally a negligible quantity. There would be much more iron in the average daily diet of an individual than is contained in a pint of so-called ferruginous wine. We may add that we have purchased samples of these Australian wines in the open market with the view of ascertaining whether they show a constancy of composition. The following are the results. Harvest burgundy (red): extractives, 3·015 per cent.; mineral matter, 0·315 per cent.; fixed acids calculated as tartaric acid, 0·277 per cent.; volatile acids calculated as acetic acid, 0·15 per cent.; alcohol, by weight 13·46 per cent., by volume 16·61 per cent., equal to proof spirit 29·11 per cent. Harvest burgundy (white):

extractives, 1·89 per cent.; mineral matter, 0·20 per cent.; fixed acids calculated as tartaric acid, 0·367 per cent.; volatile acids calculated as acetic acid, 0·114 per cent.; alcohol, by weight 13·08 per cent., by volume 16·15 per cent., equal to proof spirit 23·29 per cent. Tintara: extractives, 2·97 per cent.; mineral matter, 0·305 per cent.; fixed acids calculated as tartaric acid, 0·36 per cent.; volatile acids calculated as acetic acid, 0·12 per cent.; alcohol, by weight 12·00 per cent., by volume 14·84 per cent., equal to proof spirit 26·00 per cent. It is pleasing to record that the results obtained with the wines purchased by ourselves are in accord with the wines submitted to us directly by the wine-merchants. The purchased wines still show a heavy alcoholic strength, a full amount of extractives, and possess generally the "stout" character of these brands. The Harvest burgundy (white) is again the exception in regard to extractives, though in the case of the purchased specimen the percentage of alcohol was distinctly higher. This variation in the amount of alcohol suggests that what is present was not entirely developed in the wine itself. Iron was found in the ash in all cases but the quantity was unimportant and hardly to be considered as a feature in spite of the fact of being grown on ferruginous soil.

### BARNANGEN'S ANTISEPTIC VADE-MECUM.

(BARNANGEN'S TECHNICAL FACTORY, STOCKHOLM; MYRSTEDT AND CO., CAMOMILE-STREET, LONDON, E.C.)

The name of this preparation is unfortunate, implying a panacea for all complaints. And this sums up practically what is claimed for it. It is said to be suitable both externally and internally, and its application is recommended, amongst many other things, for the care and preservation of the mouth, the teeth, and the skin, for various skin complaints, and internally for indigestion and sickness. According to our analysis it is a spirituous solution containing chiefly menthol and oil of cloves.

### KELPION.

(THE KELPION CO., NORGROVE-BUILDINGS, 59A, BISHOPSGATE-STREET WITHIN, LONDON, E.C.)

Kelpion is described as a stainless iodine ointment yet containing the iodine for the purpose of administration in a free state. We are able to confirm this statement, for on inunction iodine soon appears in the saliva and in the urine while the skin is not stained. Kelpion contains 5 per cent. of iodine. It is a greasy, dark-olive-coloured substance which refuses to saponify with strong soda solution. It may be concluded, therefore, that the fatty vehicle does not contain a fatty acid. On heating kelpion well above its melting point iodine is liberated. Kelpion is a marked advance upon ordinary iodine unguents and is especially suitable in painful affections of the joints and for sprains and inflammations.

### KÜGLOIDS.

(CHAS. KÜGLER, PARIS; LONDON AGENCY, MR. H. H. MASON, 7, BROADWAY, NORWOOD-ROAD, S.E.)

We failed to find any special novelty about these capsules, for in reality that is what "kügloids" are. They contain a pink-coloured oil smelling strongly of creasote, and very little further examination sufficed to show that the creasote is associated with quinine in the form of glycero-phosphate, and eucalyptol and benzoic acid are also constituents. In short, the kügloid contains those antiseptics which are of service in the treatment of respiratory ailments. The combination is said to be well borne and, in addition to acting locally, to possess tonic qualities referable to the glycero-phosphate of quinine.

### MARVIS.

(THE PATENT FISH FOOD SYNDICATE, LIMITED, BERRY-YARDS, GREENOCK, N.B.)

Marvis is a clean yellowish-white powder with a fishy odour. It is not appreciably soluble in cold water, but in hot water it forms a mucilaginous mixture due partly to the normal gelatinous constituents of the fish from which it is prepared and partly to a small proportion of carbohydrates. Marvis, in short, consists practically of desiccated fish powder mixed with a little starch. Our analysis gave the following results: moisture, 11·77 per cent.; mineral matter, 3·06 per cent.; and organic matter, 85·17 per cent. The organic matters contained no less than 62·81 per cent. proteids besides fat. The latter amounted to 2·82 per cent. of the organic matters. With marvis, therefore, a very nutritious dish may be prepared. It makes, in particular, an excellent *purée*. The flavour is that of fresh fish without any suspicion of staleness. The mineral matters contained a slight amount of iodide, but consisted chiefly of phosphate of potassium and common salt. We found a small quantity of starch present which is probably added for the purpose of making the powder homogeneous. We regard marvis as a good fish food and an introduction of distinct importance in the daily dietary.

## ASYLUM REPORTS.

*County and City of Worcester Lunatic Asylum* (*Annual Report for 1899*).—The average population of the asylum during the year was 1137 and comprised 500 males and 637 females. The admissions during the year amounted to 225 and comprised 105 males and 120 females. 15 of these—viz., 7 males and 8 females—were not first admissions. Mr. George M. P. Braine-Hartnell, the medical superintendent, states in his report that of the admissions 40 were in bad health and exhausted condition and 164 in indifferent health and reduced condition. 86 patients were discharged recovered during the year, or 7·5 per cent. of the average number resident. The deaths during the year amounted to 91 or 8·0 per cent. as calculated on the same basis. Of the deaths two were due to cardiac disease, three to epilepsy, three to chronic Bright's disease, six to colitis, 11 to pneumonia, 14 to general paralysis of the insane, 20 to senile decay, and 21 to pulmonary phthisis. Post-mortem examinations were made in 76 out of 91 deaths. A married woman on admission was in a pregnant condition and was delivered of a son. "The mother, father, and brother of the patient are or have been insane, and here is this infant with such a bad 'family history' growing up and will in all probability end by marrying." "Can anyone wonder," asks Mr. Braine-Hartnell, "at the increase of insanity when people like the above marry and are given in marriage?" One inquest was held during the year on a male patient who at the post-mortem examination was found to have had three fractured ribs. No cause could be assigned, and the jury in their verdict expressed the opinion that no blame attached to anyone on the staff. One male patient on the way to recovery was one night seized with a suicidal impulse. "He smashed the window and precipitated himself to the ground. He sustained compound comminuted fractures of both legs. The left leg has since been amputated." Two male patients were attacked with scarlet fever, one female patient with typhoid fever, and there was one case of erysipelas. Colitis was the cause of death in one male and five female patients. "Phthisis accounted for 23 per cent. of the deaths. This percentage is excessive and demands serious attention. The overcrowded state of the wards is no doubt responsible in a great measure, but not entirely, for this high mortality. ..... We require separate wards in which patients showing signs of phthisis can be isolated and treated in accordance with the latest ideas." The medical superintendent suggests that in the new asylum for the county of Worcester about to be built provision should be made for an isolation block for the housing and open-air treatment of such cases. The Lunacy Commissioners in their report refer to the overcrowding in the wards, especially on the female side, and also point out that a separate ward and day-room should be set apart for the idiot children, of whom there are 17 in the asylum and who continue to be associated with the adult insane; they express the hope that the plans of the new asylum will include separate accommodation for this class of patients. They are "glad to record that advantage is taken of the means provided by the committee for the prosecution of pathological work."

# THE LANCET.

*LONDON: SATURDAY, SEPTEMBER 29, 1900.*

WE are once more on the eve of a great and important election. According to an old theory the duty of medical men was to exhibit during the time of an election a masterly neutrality and to stand aloof as if in a superior atmosphere from the raging strife of parties. We have often of late years expressed our dissent from that view. It would be strange, indeed, if the descendants of the Founder of THE LANCET should feel themselves bound to absolute silence at an election time when great issues have to be decided which must deeply affect the welfare of the nation and of the profession which is responsible for the nation's health as well as for the health of those services on the efficiency of which the very existence of the Empire at critical moments, such as we have just passed through, may depend. If such silence would be unseemly in us it would equally be inconsistent in the members of the profession which we have the honour to represent. We have no intention in thus writing of whetting the edge of mere party spirit, but we do distinctly mean to give expression to the conviction that at a time like this the quiet, ordered influence of the medical profession should make itself felt on candidates of all parties. It does not seem as if either party had done much yet to gain the confidence and the respect of the profession. There have been lamentable exhibitions of weakness in both the great parties of the State in regard to the greatest questions of medical science. Lord ROSEBERY has recently declared the late Government to be the weakest Government he remembers—except in votes; and he takes as the first and crowning example of its weakness its action in what is essentially a medical question—its dealings with vaccination. We confess that we are not altogether sorry to see this reproach levelled at the Government. Not only did it introduce into the Vaccination Acts an unprecedented individual "the conscientious objector," but it deliberately refused to carry out its distinct promise that in the session following that in which the Vaccination Act, 1898, was passed it would bring forward legislation to secure revaccination. Medical experience has amply shown this to be little less necessary than primary vaccination. On revaccination, as we know, all officials dealing with small-pox, including those of Leicester, rely as the only security against taking the disease and spreading it. But Lord ROSEBERY should remember in turning to party use this extraordinary action and inaction of the Ministry that it was the pressure of his own party that led the Government into such aberration from the lines of its projected course. At any rate the medical profession will remember this and will not too hastily assume that the tendency to fail at critical moments in legislation based on high scientific grounds is confined to one party. Rather will they trace this tendency to a vice of our political system which gives undue weight to the most prejudiced and the least enlightened section of voters.

There are other failures in legislation which illustrate this vice. In a recent leading article we alluded to several of these. For instance, the Government deliberately threw away an opportunity of guarding the public from gross injury at the hands of Companies posing as medical practitioners; the clause might easily have been passed if Mr. RITCHIE had chosen to assert his strength as a Minister with a majority of 120 or 130 at his back. Moreover, other Bills for amending the lunacy laws, for improving the position of medical officers of health and sanitary inspectors, and a very uncontentious Bill for amending the Medical Acts, failed to pass for want of a little more interest on the part of the Government in non-political questions. There is also another measure in regard to which the medical profession has a right to feel some dissatisfaction with all recent Governments, and that is the Midwives Bill, which appears as a sort of hardy annual session after session. The Medical Acts must not be tampered with. Midwives should either be left severely alone and be employed on the sole responsibility of those who seek their services or they should be strictly subordinated to the medical profession, and a Bill should be brought in, as Sir WALTER FOSTER suggested, on the responsibility of the Government. It is not fair to lying-in women among the poor or to the medical profession that the subject should be dangled incessantly before Parliament with the risk that in the last hours of an expiring session a new class of semi-medical practitioners may be created and all the old "Gamps" left unmolested to prosecute their dirty and deadly business.

It goes without saying that we make no suggestion to our readers as to the party which they should support, but we venture to impress upon them the duty of using the election as a means of asserting the due influence of the profession in regard to questions having medical bearings and of great public moment. If "a wise physician skilled our wounds to heal is more than armies to the public weal," what may not be the value of the judgment of the whole profession at a time like this when the reorganisation of the medical services is contemplated, when the profession itself is pressed with new problems, and when public bodies are charged with ever-multiplying duties of a semi-medical kind? He must be an obtuse observer who does not perceive that questions of mere medical politics are little liked in Parliament and are severely evaded by Ministers. There is the more reason for medical men to assert themselves in general politics. It may be said that this will be unsafe as regards their professional prospects, that their *clientèle* will include men of various shades of political opinion, some of whom will be sure to be offended with their action. We very much doubt the risk and, if we admitted it, we cannot allow that it should be regarded by any self-respecting member of the profession. The election strife carried on in the manner satirised by LOVER, THACKERAY, and DICKENS may be left to the uneducated, but true politics—i.e., the science of what is best for the State, and the use of

knowledge, knowledge of health and illness, of disease and its prevention—are for the educated, and so long as this knowledge is used with dignity and discrimination so long will its exponents be respected by the men of all shades of political opinion. It is for men of liberal professions to use elections so as to raise the whole spirit and standard of political discussion.

---

A PARLIAMENTARY paper dated July 9th, 1900, has been published by the India Office containing the correspondence which has taken place between that office and the Government of India on inoculation against cholera and typhoid fever. There is no need on this occasion to touch upon the first-named part of the subject, and we may confine our attention exclusively to that part which concerns preventive inoculation against typhoid fever in India. Everybody at all acquainted with the medical history of India knows the terrible drain on the young manhood of this country caused year after year by the ravages of that disease. The matter is one which gravely concerns the health and efficiency of the British army and civil service of India, but more especially the young officers and soldiers serving in that country. The aggregate loss of life caused by enteric fever is simply deplorable, to say nothing of the serious illness it always, and of the wrecked health and invaliding which it so often, occasions. In spite of all the efforts that have been made to prevent or limit the extent of its prevalence it cannot, unhappily, be said that up to the present time they have been attended with success. Under such circumstances it is not easy to exaggerate the importance of experimentally testing the value of any prophylactic method of treatment which is based upon approved scientific principles and bacteriological investigations and which promises to be of real value. Major RONALD ROSS, I.M.S., of whose scientific investigations in connexion with malaria and the malarial parasite it would be difficult to speak too highly, has brought a serious indictment against the India Office in a letter published in the *Times* of Sept. 24th, wherein he severely criticises its action in this matter of inoculation against typhoid fever. Major RONALD ROSS, in his comments on the published correspondence on the subject of inoculation against typhoid fever, says:—

"The paper contains a statement which appears to be of the most serious nature—that the Secretary of State for India refused in 1898 to permit officers and soldiers to undergo this inoculation even voluntarily. It was not merely a refusal to give the inoculation Government assistance, but a refusal to allow it to be practised on Government servants at all, even if they wished it. This ruling was made in opposition to the advice and wish of the Government of India, and seems to be still in force—though it appears to be equally opposed to the private liberty of the soldiers, the health of the army, and the progress of science."

We confess that a cursory perusal of the printed official correspondence in question did not convey to us the impression that the Government had, under the circumstances stated, once and for all expressly prohibited the practice of inoculation against typhoid fever, otherwise we should have felt compelled to concur entirely with the view taken by Major ROSS. Neither does a subsequent reference on our part to the paper containing the official correspondence make out so bad a case against the India Office as stated. It is not quite plain to us that the Government had any intention of issuing any peremptory and prohibitive order against voluntary inoculation, and we can only conclude that there has been some misapprehension in the matter. The facts set forth in the published correspondence according to our reading are somewhat as follows:—

The Government of India in November, 1897, proposed that the services of the professor of pathology at the Army Medical School, Netley, should be lent to them for four months to carry out his system of inoculation against typhoid fever. The Secretary of State for War was unable to assent to such proposals for certain alleged reasons, which might have been right or wrong, but need not concern us now. His decision was conveyed without comment to the Indian Government in a military despatch dated March 3rd, 1898, and was communicated in the usual manner for the information of the Commander-in-Chief and Principal Medical Officer of Her Majesty's Forces in India. But as it was understood that Lord LANSDOWNE'S objection to the introduction of the treatment applied to the formal authorisation of inoculation at the public expense rather than to voluntary operations at private cost, advantage was taken, under that supposition, of the presence in India of Professor WRIGHT as a member of the Plague Commission, and the practice was carried out at certain stations though without the sanction of the Indian Government or of the Commander-in-Chief. Over 2000 soldiers were voluntarily inoculated. On the facts being known orders were issued to stop further inoculations. But in conveying this information to the India Office the authorities in India—including the Government, the Commander-in-Chief, and the Principal Medical Officer—strongly urged that Her Majesty's Government should reconsider its objection. This was apparently done, for in a letter from the Government of India to the Secretary of State for India, dated March 8th, 1900, it is stated that "since receiving your approval of the resumption of inoculation at the public expense in August last the measure has been largely resorted to, and we have hopes that the results will be satisfactory in securing some considerable degree of immunity, especially to young soldiers during their first year of service." In a despatch from the Secretary of State for India, dated May 10th, 1900, the receipt of the interesting report of the Principal Medical Officer of Her Majesty's Forces in India, with the remarks of the Indian Government on the subject, are acknowledged and returns are called for as soon as sufficient data are available.

---

THIS is an age of congresses. During this year especially a large number of assemblies of scientific and other bodies are being held to read papers on and discuss many matters connected with the bodily or mental welfare of mankind. It is, however, with congresses on subjects connected with the science of medicine that we are more closely interested. It is a natural question to ask whether according to the manner in which they are now conducted

the greatest good results from them or whether certain modifications might be made in their arrangements by which more material results might be obtained. We are afraid that one fact cannot be disguised, and that is that a "congress" of any kind is often an excuse for a number of men to flock together in order to take part in various social festivities and excursions under the self-deception that they are adding to the success of the meeting by swelling the number of names placed in the attendance list. A large number, no doubt, "look in" for a short time at one or more of the "sections," but it is only a minority who enter into the serious work of the congress. Not a few attend and read papers on their own particular subjects, but no discussion ensues and little good results. The "opening addresses" by the presidents of the various sections or by some eminent physician or surgeon are listened to by large audiences, are of general interest, and are frequently some of the most valuable contributions to the literature published in the shape of "proceedings" of the congress. A certain number of subjects for discussion are also chosen by the officials of each section. Recognised authorities are selected to open the debates, and several other well-known observers are invited to take part. Such discussions are generally a success and much useful information is thereby obtained. But the same cannot be said of some of the other, of those which may be termed private, contributions already alluded to. Many of these seem simply framed to air some theory or grievance of the author and much useful time is lost in listening to the reading of such dissertations.

It is difficult to suggest means by which the above defects might be remedied. The main objection to the social arrangements is that the crowding thereby caused is a source of discomfort to those who are entirely bent on the scientific aspects of the meetings which, of course, should have first place. Another objection is that the necessary amount of entertainment involved, and the expense thus incurred, cause certain communities to hesitate before sending an invitation to a congress to assemble in the town. A certain amount of hospitality, of course, is to be expected, but the extreme to which this has been carried is to be deplored. A public reception of the officials and delegates is a graceful recognition of the importance of the meeting, but to expect numerous banquets and large garden parties to be given by private individuals is to place too great a tax upon hospitality. The vast majority who will accept such invitations take but very little, if any, part in the real business of the congress, whilst the secretaries of sections and others who have given much labour to the organising and management of the discussions have no time to attend. We would suggest, therefore, that the system of inviting public bodies and societies to send delegates to represent them at congresses might be extended and that as far as may be public receptions only should be given, special invitations being sent to such delegates, and that when possible the expense of such receptions should be in a great measure defrayed by the funds at the disposal of the organising committee. Such a procedure would certainly lessen the total number of members attending a congress, but we believe that the actual scientific work accomplished would be increased rather than diminished. Another suggestion we would make is that longer notice should be given of the subjects chosen by the committees of the various sections for discussion. Papers contributed by other members on their own initiative need not be discouraged, but it should be clearly intimated to the authors that an opportunity for reading them would only be afforded if time permitted after the official discussions had concluded. A further point for consideration might be whether it would be advisable to appoint a committee to consider the contributions sent in and only to accept a certain number for publication in the proceedings. By giving longer notice, as above suggested, ample time would be given for those who intended to take part in the discussion to undertake fresh observations or corroborate those already made. At the sittings of the congress much valuable material would thus be produced and full opportunity would be afforded for analysing and criticising the work accomplished. If only a few subjects were chosen the discussions would not have to be closed prematurely as is now so frequently the case.

Congresses in the past have done good and valuable work. Lasting and deep-reaching results have been obtained from such gatherings and they have been the means by which legislation in many countries has been effected. The resolutions adopted have been forwarded to the proper authorities, with the result that action has been taken which has been of the greatest benefit to the community at large. It is, of course, open to argument as to how far the social element should be modified. There are certain international advantages to be obtained from men of science from all parts of the world meeting together in friendly concourse apart from the essential scientific purposes of the meeting; but such assemblies have not been free from disadvantages of which, perhaps, overcrowding has been the greatest. We offer the above suggestions, not as reflecting mismanagement on the part of the organising committees of past congresses, but in the hope that in the future modifications on the lines we have hinted at may increase the value of discussions which are the result of much thought and labour.

---

WHILE public attention is still occupied with intelligence from the theatre of war everything about the wounded in war is read with interest. At the present time a number of soldiers may be found in our military hospitals who have been invalided from South Africa suffering from the effects of bullet wounds and other injuries received during the campaign. A state of lowered health and nervous depression which seems altogether out of proportion to their local injuries is unhappily very often present in such cases. It is perhaps only natural under the circumstances to seek for some explanation of the causes of this nervous condition outside those of a physical kind. In an article which appeared in THE LANCET of Sept. 15th (p. 807) Mr. MORGAN I. FINUCANE, civil surgeon attached to the Connaught Hospital, Aldershot, seems disposed to ascribe the state of such patients to the immediate or remote result of general nervous shock. He states that if the gunshot injuries of modern arms have apparently lost much of their seriousness, it would, nevertheless, appear that the resulting nerve-shock and injury to

the nervous system form some of their most permanent sequelæ, and he states that it is most difficult to treat such cases. He apparently suggests that some of the causes which are largely responsible for the development of such nervous phenomena may be of a moral rather than of a physical kind; that, quite apart from the surgical injuries sustained in such cases, they may be traceable possibly to the panic and disaster arising out of badly conceived projects. We think, however, that a perusal of the cases which he describes will lead to the conclusion that in some of them at least the conditions have arisen from the presence of physical causes. But, be this as it may, we doubt very much if this view is a tenable one. While it is easy to have recourse to speculative hypotheses of this kind, it would, we think, be very hard to prove them. And, what is more, the facts connected with the present war (if it is intended to imply that any widespread degeneration of the *morale* of our troops has taken place) all tend to point, and very decidedly so in our opinion, in the opposite direction.

It must be admitted that this war has been of an unprecedented character. It is not easy to conceive circumstances of a more trying description—an enemy who could not be seen and refused to be drawn, entrenched or occupying almost impregnable natural positions, frequent ambushes, smokeless powder, and the opposing Boers only disclosing themselves by firing when our attacking troops were in sufficient numbers and at the most favourable distances. But our troops boldly faced these conditions again and again with the most unmistakeable courage, their only regret being that they could not get at their foe face to face in the open. Men who know what war is and who have previously seen our troops fighting in the Indian mutiny and elsewhere have declared that there has been no falling off in their fighting qualities in South Africa, and officers from foreign armies—from Russia, Germany, Sweden, and America—one and all, have extolled their bravery, cheerfulness, and tenacity. The soldiers who have accompanied and fought under General BULLER in his hardest fights on the heights of Natal and the remnant of the besieged army of Ladysmith have been transformed into veterans and have since been following him, storming heights and capturing positions with undaunted vigour and confidence in a mountainous country like that of the Tyrol. They, to say nothing of the troops with General FRENCH and other generals, have passed through terrible ordeals. They must have gone through states of nerve tension again and again, but apparently only to become seasoned to danger instead of degenerating. It is simply a platitude, of course, to assert that men are not all constituted alike as regards courage and fortitude, and even the bravest men are well known to differ greatly in the way in which they bear pain; but the history of this war has served to bring out the fact that the courage of the wounded has been undaunted and that their thoughts while in hospital have not been concentrated on themselves but rather on their comrades in the fighting ranks at the front. In the possession and display of this quality, too, there has been no difference between the veterans of the regular army and the colonials and volunteers who had never previously seen a shot fired in actual warfare. While we may readily allow that the terrible stress and strain of battle may make an indelible impression on the nervous system and prejudicially affect the health and retard the recovery of the wounded, it nevertheless seems astonishing that such an occurrence is not more frequent than it is. Where the nerve-centres or nerve-trunks are injured the case is different of course.

The soldier's "nerve" is, we know, not everything. Great strategical and tactical ability and skill and other qualities of mind and character are likewise necessary for the successful conduct of war, but the empire has nevertheless reason to be profoundly grateful to Providence that our race is not lacking in that splendid physical courage which, after all, is, and must always be, the foremost characteristic of the soldier.

**"Ne quid nimis."**

## EXPERIMENTAL PROOF OF THE MOSQUITO-MALARIA THEORY.

WE publish an interesting article by Dr. Patrick Manson on the Experimental Proof of the Mosquito-Malaria Theory. A large amount of literature has recently appeared on the subject and the results of the various expeditions which have been despatched to malarious districts to investigate the causal relationship of mosquitoes and malaria are well known. Dr. Manson points out that it is of supreme importance that the public generally, more particularly those who reside in regions where malaria is endemic, should be convinced that certain species of mosquitoes can convey the disease to man. There is no proof so telling as experimental proof. Consequently Dr. Manson cast about for means by which the conversion and coöperation of the public might be secured. The tertian variety is the least harmful, and for obvious reasons the experimental insects were fed on persons suffering from this form. Mr. P. Thurburn Manson offered to submit himself to be bitten by these insects which had been forwarded to England, with the result that he became infected with an attack of tertian fever. Full details of the experiment will be found in Dr. Manson's paper, and the thanks of all are due to his son for thus having practically demonstrated the truth of what had hitherto been theory. Experiments equally important were carried out by Dr. Sambon and Dr. Low, Signor Terzi, and two Italian servants, in the Roman Campagna at a spot known to be intensely malarial. By taking every precaution against the bite of the mosquitoes they remained entirely free from infection, in marked contrast to their neighbours, who were either ill with fever or had suffered malarial attacks. Dr. Manson's remarks on these experiments are to the point and should lead to the adoption of precautions whereby a terrible and widespread evil may be prevented.

## THE GENERAL ELECTION.

IN less than a week from the time when we go to press the general election will have commenced and our readers will, no doubt, find interesting a list of the members of their profession who have decided to contest seats. The following members of the late Parliament have, we understand, decided to appeal again to their constituencies. R. Ambrose, L.R.C.P. & S. Edin. (Mayo West); G. B. Clark, F.R.C.S. Edin. (Caithness-shire); John Dillon, L.R.C.S. Irel. (Mayo East); R. Farquharson, M.D. Edin. (Aberdeenshire

West); Sir B. W. Foster, M.D. Erlang., F.R.C.P. Lond. (Derbyshire, Ilkeston); Sir M. Foster, M.D. Lond., K.C.B. (London University); J. F. Fox, M.D. Univ. Cincinnati, F.R.C.P. Kingston, Canada (King's County, Tullamore); M. A. MacDonnell, M.D. R.U.I. (Queen's County, Leix); Sir George Pilkington, M.R.C.S. Eng., L.S.A. (Southport Division of Lancashire); C. K. D. Tanner, M.D., M.Ch. R.U.I. (Mid Cork); and Sir J. Batty Tuke, M.D. Edin. (Edinburgh and St. Andrews Universities). The following are the new candidates so far as we have at present ascertained: Conan Doyle, M.D. Edin. (Edinburgh Central); A. P. Hillier, M.D. Edin. (Stockport), V. H. Rutherford, M.B. Cantab., L.R.C.P. & S. Edin. (Yorkshire, Osgoldcross). Sir Charles Cameron has, we regret to hear, decided not to seek re-election at the hands of his Glasgow constituents. It should be noted that Sir R. B. Finlay, the Attorney-General, who seeks re-election for Inverness Burghs, is an M.D. of Edinburgh, and was at one time a medical practitioner, while, as many of our readers are aware, Sir W. Cameron Gull, Bart., Q.C., who is seeking re-election for the Barnstaple Division of Devonshire, is the son of the late Sir William Gull, M.D.

## WORKHOUSE NURSING.

AT a recent meeting of the Hampstead Board of Guardians some dissatisfaction was expressed because the medical officer of the workhouse, Dr. E. C. Taylor, had directed that a trained nurse should be engaged to attend on a child in the workhouse who happened to be suffering from measles. The chairman of the board was reported in the local press of Sept. 15th to have said that the child could have been attended to by any of the women engaged to look after the children and that it was a monstrous thing to go to the expense of having a trained nurse. Unless "the women engaged to look after the children" are accustomed to nurse severe cases of illness, we are decidedly of opinion that the chairman's views are retrograde and in every way unfortunate. In home nursing the ties of affection among relatives serve in some degree to make up for want of proficiency in the duties, but long experience has demonstrated that amateur nursing in Poor-law institutions is only too apt to be conspicuous for its shortcomings.

## POISONING BY COAL GAS.

IN THE LANCET of Sept. 15th, p. 820, we had occasion to condemn the water-slide gas pendant as a most dangerous fitting, prone indeed to such a number of defects as to warrant its exclusion altogether from household appliances. This conclusion was based upon a case of coal-gas poisoning at Birmingham in which it was shown that one life was lost (and nearly two) through the defects of this clumsy gas accessory, but there is quite a historical record of the dangers of the chandelier. Another remarkable case of coal-gas poisoning has since occurred, but this time it was due to a defective shilling-in-the-slot meter. It would appear that the meter was fixed without being tested by the gas-fitter of the company for the reason that he had not got a shilling for making the test, nor did the company instruct him to inaugurate the working of the meter unless the shilling was supplied by the consumer. According to the evidence brought forward at the inquest, however, the meter leaked in spite of the fact that no shilling was put in the slot, and this leakage cost two lives, those of a father and son. We are surprised at the extraordinary method of the company and trust that such a procedure is not the universal rule. Clearly it was the duty of the company's official to have tested the meter and to have ascertained that it was fixed properly. The meter, it should be remembered, is the property of the company. The jury, however, found "that the deceased died from suffocation by coal gas the result of an escape at the meter and that such deaths were due to accidental causes." In our opinion it should be impossible for such an "accidental" cause as this to arise and the gas companies should be compelled to test a meter after it has been placed in position and should be made responsible for any consequences that may arise from its defective attachment. In the *Journal of Gas Lighting* of Sept. 18th appears an article on questions of gas poisoning in which an appreciative and complimentary reference is made to our attitude which was defined in an annotation in THE LANCET of Sept. 15th on the question of the danger of water-slide gas pendants and the subject of coal-gas poisoning in general. But in view of the recent case of coal-gas poisoning through a defective meter we cannot refrain from quoting two sentences in this article and placing them side by side with the evidence which was given by the gas-fitter in the employment of the Tottenham and Edmonton Gas Light and Coke Company at the inquest held on Sept. 22nd:—

| *Morning Leader*, Sept. 24th, 1900. | *Journal of Gas Lighting*, Sept. 18th, 1900. |
|---|---|
| William Shields, of the Tottenham and Edmonton Gas Light and Coke Company, who fixed the meter stated that he asked Mrs. Sanders for a shilling to test the meter, but was several times refused. He left the meter untested. Had he been given the shilling he would have discovered the leak at once. When he tested the meter in the presence of the coroner's officer he found a leakage in the outlet pipe to the extent of one foot in 20 minutes. | The use of town's gas is increasing so fast, and spreading so widely among the poorer and less educated grades of the community, that accidents must be expected now and again. The circumstance that the users of prepayment gas-meters have their fittings put in by the gas company is an effectual protection against any mishap attributable to flimsiness of material, unsafe design, or fraudulent workmanship on the part of some local fitter. |

We take it that the writer was referring to the ordinary gas-meter, but surely the same "effectual protection" should be afforded (if such is the case) when slot-meters are fixed. If not the company should be held responsible for any accidents which arise through the defective fitting of the meter which they supply.

## ALLEGED HOSPITAL MISMANAGEMENT.

NOT infrequently reports of inquests and other inquiries appear in the daily press which tend to throw considerable discredit upon hospital management. Fortunately, in the great majority of cases investigation shows that the facts have been grossly perverted or are entirely devoid of truth. Quite recently an inquest was held on the body of a man, aged 46 years, who had suffered from "paralysis" for some years. Whilst walking along the street he stumbled and fell, striking his arm violently on the kerb. He gradually became very ill and was taken to the Camberwell Infirmary, where he died. It was then ascertained that he had sustained a comminuted fracture of the right arm near the shoulder, the cause of death being "pneumonia consequent upon the injury." It was stated in evidence that he had said that he had been attending St. Thomas's Hospital for the injury, and Mr. W. J. C. Keats, the medical superintendent at the Camberwell Infirmary, drew attention to the fact that the arm was simply bandaged and not put in splints, as it should have been, and naturally added that whoever examined the arm could not have done so thoroughly. The second case which came before the same coroner was that of a man who was thrown from a hearse and was taken to St. Thomas's Hospital, where his side was strapped and he was allowed to go home. He subsequently died from bronchitis. It was alleged that the strapping was only applied at the request of a friend of the injured man. The coroner on each occasion allowed remarks from the jury which threw all the blame on the medical officers of the hospital and intimated that he should write to the hospital

authorities on the subject. In doing this he was acting perfectly within his duty, but it would have been well if he had requested the jury not to have censured the hospital officials without further proofs of the alleged neglect. We have made inquiries at the hospital which place a very different complexion on the two cases and entirely exonerate the house surgeons. The man with the fractured arm does not appear to have been treated at the hospital; his name does not appear in the casualty book and none of the officials on duty have any recollection of such a case. The patient erred, therefore, in stating that he had been to St. Thomas's Hospital. With regard to the case of fractured ribs, the house surgeon strapped the chest as the best method of treatment and not at the suggestion of the patient's friend. Unless there is some complication such cases are not admitted as in-patients, and when the man was examined there was no bronchitis. It is to be regretted that reports such as those to which we have alluded above are so widely published in the lay press; full inquiries should be made before responsible bodies such as coroners' juries are allowed to make remarks which unjustly tend to damage the reputation of our large hospitals by alleging carelessness in examination and want of proper treatment on the part of the medical officers.

## INTOXICATION BY CANNABIS INDICA.

IN the September number of the *Edinburgh Medical Journal* Dr. James Foulis of Edinburgh gives a lengthy account of two cases of poisoning by cannabis Indica. The patients were brothers, A and B. A was 22 years of age and was a medical student in his third year; B was 20 years of age, an art student, and of a highly strung and sensitive nature. Both of them were tall and powerful, being nearly six feet in height. When Dr. Foulis, who had been hurriedly sent for, arrived at their house he found them in the dining-room, alone and only partially dressed. A was hanging tightly on to B who was rushing round the table in a very excited state, wildly throwing his arms about and singing in a most jovial manner. A was evidently doing his best to control B; he looked pale and depressed as if overweighted by some sense of heavy responsibility. Both in mind and body B was in a state of extraordinary excitement. He appeared as if he could not talk fast enough and as if his arms and legs were acting automatically. B threw his arms round Dr. Foulis in a loving embrace and spoke most kindly and even tenderly to him, then all of a sudden he began to quote poetry and in an excited manner asked which poet Dr. Foulis liked best, naming several one after another. As the other inmates of the house were unable to control the young men they were removed to the Edinburgh Royal Infirmary where they arrived about 1 A.M., two and a half hours after having taken the drug, and at 9.30 A.M. they were sufficiently recovered to return home. A, the medical student, afterwards wrote a description of the occurrence, in which he stated that with a view of experiencing the wonderful dreams said to be produced by haschish or cannabis Indica his brother and he on three successive occasions took doses of the drug. On the first occasion they took 25 minims of the tincture, on the second occasion (a week later) they took over 40 minims, and on the third occasion (three weeks later) they took over 90 minims, with the results above described. In about 20 minutes they both began to feel exhilarated. A felt decidedly pleased with himself and versatile. Then one of the figures in a drawing at which he was looking began to nod and whirl round. Suddenly he felt himself carried away as it were by a whirlwind and finally lost consciousness. The next thing he remembered after regaining consciousness was the room heaving up and down. When Dr. Foulis arrived on the scene a most vivid picture presented itself to A's mind. He seemed to see Virgil and Dante standing on a rocky ridge overhanging a deep abyss whence were issuing multitudes of lost souls on their way to Hades. A imagined himself standing on that ridge watching the unending and ever-moving throng passing out of sight. The effect of the drug lasted to some extent for three or four days, during which they were in an extremely unstable state of mind and had to keep a constant guard over their actions. On the afternoon of the following day B had another attack. B's account of his dreams on falling asleep at the Infirmary was as follows: "Upon falling to sleep I experienced the most exquisite dreams. The sky was scintillating with delicate colours rapidly succeeding one another. Then came shifting landscapes of unimaginable beauty, following fast upon each other, and all too quickly disappearing." It is of some interest to compare the foregoing account with Mr. Havelock Ellis's description of the intoxication produced in himself by mescal buttons (the fruit of the Anhalonium Lewinii) as recorded in THE LANCET of June 5th, 1897, p. 1540.

## MASONIC HONOUR TO SIR GEORGE HARE PHILIPSON.

SIR GEORGE HARE PHILIPSON, M.A., M.D. Cantab., D.C.L. Durh., F.R.C.P. Lond., was recently entertained at dinner by his brother Freemasons of Northumberland and Durham to celebrate his knighthood at the hands of Her Majesty and to testify to the esteem in which he is held by Freemasons and by the medical profession. Quite a large gathering of Freemasons, among them being many medical man, assembled at the County Hotel, Newcastle, where the dinner was held under the chairmanship of R.W. Bro. the Right Hon. Sir Matthew White Ridley, Provincial Grand Master of Northumberland. The toast of "Our Guest" was most enthusiastically received and drunk with musical honours. The Chairman, in proposing it, said it was an open secret that the medical profession intended to do honour to their guest in their own way, but he was certain that the Freemasons of the two counties were not less anxious to show Sir George Philipson the honour which he deserved than was the medical profession. For 28 years Sir George Philipson was acting physician at the Newcastle Infirmary and was never a day absent from duty. That in itself was an honourable career, and they all knew how much the infirmary owed to him. He was at the head of the medical profession in the North of England, and no man deserved better all the honours which had been conferred upon him than did their guest. In every walk of life Sir George Philipson had endeared himself to every section of the community.

## IDIOPATHIC TRANSITORY CLOUDING OF CONSCIOUSNESS.

UNDER the above title Dr. Placzek of Berlin reports some interesting cases in an article recently published in the *Berliner Klinische Wochenschrift*, No. 32, 1900. Two of the cases were examples of temporary loss or disturbance of consciousness amounting to mental aberration and therefore important from a medico-legal point of view. The first case was that of a woman, aged 40 years, who suddenly one afternoon and without any warning became irrational in language and behaviour, gesticulating wildly and talking unintelligibly. This condition lasted for six hours (till 8 P.M.), when she recovered. She, however, had no recollection of her state or conduct during these six hours. It was found that she was menstruating at the time of this attack, but no connexion could be traced between menstruation and her illness. The following day she had a typical attack of migraine with muscæ volitantes, scotomata, and other visual disturbances. She was said to have suffered at times from headache, but she was free from any stigmata, hysterical

or epileptic, and her previous history was good. The second case was that of a man, by occupation an engine-stoker, who suffered from an attack of clouding of consciousness. During this condition he failed to recognise his friends and relatives and was very irritable and rough in manner. This condition lasted only a short time and then in the course of an hour he suddenly recovered. He was stated to have been a sufferer from trigeminal facial neuralgia and painful cramps of the muscles of mastication. In discussing the causation of these seizures Dr. Placzek thinks that there occurs in these cases a marked disturbance of the cerebral circulation, and refers to somewhat similar symptoms which are met with in those who have been resuscitated from strangulation by hanging—a condition in which one of the most marked features is the constriction of the carotid arteries in the neck. It is of importance to recognise that such occurrences as temporary clouding of consciousness and loss of emotional control may occur, apart from epilepsy, hysteria, or insanity, and in persons free from grave neurotic or traumatic taint. Dr. Placzek refers to a few such cases which have been recorded in literature by Azam, Krafft-Ebing, Möbius, Charcot, and Féré, and which possess a practical and medico-legal bearing.

## ROYAL ARMY MEDICAL CORPS SOUTH AFRICA FUND.

SUBSCRIBERS to this fund will recollect that the committee sent £200 to the principal medical officer in India to be expended on warm clothing for the Indian dhoolie-bearers and hospital servants. No formal acknowledgment having been received Surgeon-General H. S. Muir wrote on August 10th to the principal medical officer asking if he could give any information. Surgeon-General W. Taylor, in reply, mentions having duly sent a copy of the subjoined letter soon after he received it but it never reached its destination.

Copy of a letter dated June 23rd, 1900, from the Secretary to the Government of India Military Department to the address of the principal medical officer, Her Majesty's Forces in India.

"1. I am directed to acknowledge the receipt of your letter No. 2491, dated June 14th, 1900, reporting that a consignment of warm clothing—namely, khaki serge blouses and knickerbockers, puttees, and puggarees provided from funds placed at your disposal by the committee of the Royal Army Medical Corps South Africa Fund—has been despatched by the Royal Indian Marine ship *Clive* to the General Officer Commanding Line of Communications, Natal, for distribution among Indian hospital followers in Natal. 2. With reference thereto I am to request that the thanks of the Government of India may be conveyed to the committee for their generous gift."

## EX ORIENTE SEMPER ALIQUID NOVI.

A PAPER on the Reorganisation of the British Medical Association was read before the Hong-Kong and China branch of the association by Surgeon-General G. J. H. Evatt on April 29th, 1898, and has just been published as a pamphlet of 31 pages by Messrs. Hoyten and Cole, Russell-street, Plymouth. To carry out his proposals would involve great changes in existing methods. Commencing with the branch organisation he recommends that the county should be the "unit" and the Parliamentary electoral division the "primary unit." There is no objection, he says, to several counties uniting in a branch, but each county ought to have its own separate and complete organisation for county purposes, to advise and to watch the proceedings of the county council of the county, "a source of constant anxiety as to its action regarding medical men." There should, therefore, be in every county within the branch a district or county council of the British Medical Association under its own chairman (not president) and with its own secretary for the county. When election time comes round the "primary units" can by letter or interview make known their opinions to the local competing candidates and obtain replies. For scientific work he would create an academy of medicine for the county or branch, having as its *ex-officio* principal the chairman of the British Medical Association district or county council. With regard to the central organisation of the association, he would have the president elected by "the universal suffrage of every member, attached or unattached," of the association, voting papers being used, as in the election of Direct Representatives on the General Medical Council. This president would have a good salary, at least 1*s.* per member per year, would wear a badge and chain of office, and would hold office for three, four, or five years. Surgeon-General Evatt has a good deal to say with respect to the *British Medical Journal*, but perhaps his most startling recommendation is that the sections of the annual meetings should be raised into faculties with professors and deans of faculties, that these faculties should be grouped into post-graduate colleges established in different parts of the United Kingdom, and that these colleges should in time be combined "into a post-graduate university conferring a Doctorate in Medicine, a higher degree in surgery like the F.R.C.S., and finally a D.P.H. diploma."

## TWISTING OF THE PEDICLE OF A PAROVARIAN CYST DURING PREGNANCY.

IN the *Boston Medical and Surgical Journal* of August 30th Dr. F. B. Lund has published a case of this condition. Torsion of the pedicle of parovarian cysts is rare because their pedicles are short or even absent, and because the tumours are regular in form. On July 13th, 1899, at about 4 P.M., a married woman, aged 27 years, while reaching over a table was seized with severe pain in the right inguinal region accompanied by vomiting. She was seen at 8 P.M. when she was in bed and complained of severe pain in the right inguinal region, which recurred every 10 or 15 minutes. Her second and youngest child was born 10 months before. Menstruation had returned seven months before and been regular until three months before, when it ceased. She had morning sickness, vaginal discharge, and increased frequency of micturition, and believed herself to be three months pregnant. Examination revealed a fluctuating abdominal tumour larger than a three-months pregnant uterus, which extended upward to the umbilicus, occupied the hypogastric region, and extended more into the right than the left inguinal region. On bimanual examination the cervix was found to be soft and patulous and an extremely tender mass was felt in the right fornix. Owing to the spasm present the epigastric tumour could not be distinguished from the uterus. The temperature was 100° F. and the pulse was 90. The pains continued during the night. In the morning a small tender mass was felt in the right iliac region suggesting a swollen appendix. Appendicitis with pregnancy of longer than three months' duration (to account for the large size of the supposed uterine tumour) were thought probable. A short incision through the outer part of the right rectus muscle revealed a twisted pedicle which was composed of broad ligament and enormously dilated veins, some of which must have been ruptured, as there were extensive sub-peritoneal ecchymoses. A cyst with thin translucent walls and dark from dilatation of its vessels was seen behind and above the uterus, which was of the size of a three months pregnancy. The rectus incision was sewn up and a longer one was made in the linea alba. The cyst was tapped and about a quart of thin smoky fluid was removed. The pedicle, which was twisted about three times on itself, was untwisted and tied in sections with silk. Recovery was uneventful. Examination of the specimen showed it to be a parovarian cyst with a

capacity of 700 cubic centimetres. In January, 1900, the patient was delivered of a son.

## THE LATE SIR JAMES PAGET.

SIR JAMES PAGET'S memoirs and letters, with selected essays and addresses, are being prepared for publication. We are asked by Mr. Stephen Paget (70, Harley-street, W.) to say that he will very gladly receive any letters, or copies of letters, that may be sent to him for this purpose.

## FACTORS IN LIFE ASSURANCE.

IN his presidential address delivered before the Life Assurance Medical Officers' Association Dr. C. Theodore Williams dealt with the question of Race in Relation to Life Assurance and gave some interesting details as to the mortality and expectation of life in various European States. Taking an average of 25 recent consecutive years the deaths per 1000 of the population in the several countries were found to be as follows:—United Kingdom, 19·6; England and Wales, 19·8; Scotland, 20; Ireland, 18·1; Denmark, 18·8; Norway, 16·8; Sweden, 17·3; Austria, 29·9; Hungary, 35·4; Switzerland, 21·7; German Empire, 25·2; Prussia, 24·9; Netherlands, 21·8; Belgium, 21; France, 22·6; Italy, 27·8. The figures for 1897 in every case show a reduction on the 25 years' average except in Ireland, where the rate rose from the 25 years' average of 18·1 to 18·4 in 1897. Norway appears to possess the lowest death-rate in Europe, the figures for 1897 being only 15·4. With regard to complete expectation of life in different countries, the British figures are at all ages slightly less than the American and slightly greater than the German and French. At 20 years of age the figures are: American, 42·199 years; British, 42 101 years; German, 39 683 years; French, 41·839 years. At 60 years of age the figures are: American, 14·098 years; British, 13·808 years; German, 12 848 years; French, 13 287 years. In a paper on Locality and Occupation in relation to Life Assurance, read before the same Association by Dr. G. V. Poore, attention was drawn to the exceptionally high mortality of inn and hotel servants in London and to the prevalence of phthisis among them, their mortality from this disease being four and a half times that of occupied males in agricultural districts. Dr. Poore considered that the liability of this class of workers to phthisis and respiratory disease was largely attributable to the design of the houses in which they live.

## ABNORMAL NERVE-SIGNS AND OTHER DEFECTS IN CHILDREN.

A COMMITTEE of the British Association presented a report at the last annual meeting summarising an extended series of observations on the face, hands, and eye-movements of children, as signs of their brain condition indicated by attitude and movement. The facts upon which this report was based are "all the cases with any abnormal nerve-signs, occurring in the records of the Childhood Society among the 50,000 children examined." The cases are grouped as presenting signs in (1) the face, in its expression, frowning, grinning, &c.; (2) the hand, in its balance or finger-twitchings; (3) the eye-movements, as wandering or not under control; (4) in balance of the head, spine, or other parts, &c. The report says, in making a rapid observation of children it is sometimes convenient to examine and classify cases according to the part of the body in which irregular action is seen, in place of indicating the detailed points observed, though 21 signs in all have been defined. It appears that the hands when held out free on direction to do so were in 1520 boys and 1138 girls dropped, slouching, held asymmetrically, or showed finger-twitching and over-action. The face in 1133 boys and 570 girls was lacking in expression and tone or showed twitches and other irregular action, while "eye-movements" were not well under control in 351 boys and 259 girls. It is thus obvious that much may be learned from the hand-balance and steadiness of the fingers as signs of a well-trained brain or its disorderliness; these points, as well as good control of the eyes to attention under direction and good expression in the face, are objects that deserve careful notice both in diagnosis and in school training. This is the eighth annual report of the committee. Among results of their work evidence has been advanced on many interesting problems. With certain constitutional conditions of congenital deficiency and acquired defects as found among boys and girls respectively, the status varies in the age-groups. The main classes of defect are more frequent with boys, while the girls with defective constitution tend in larger proportion than the boys to ill-health. The heavy mortality of infancy falls principally on the boys and is largely due to developmental defects, while the children with such congenital defect who survive add largely to the number of dull and delicate persons in after-years. It has been shown that good effects follow the employment of physical training at school in diminishing the proportion of dull pupils. An important mathematical paper on Association of Attributes in Statistics, with Illustrations from the Material of the Childhood Society, &c., by Mr. G. Udny Yule, has been published in the Philosophical Transactions of the Royal Society, affording confirmation of some of the deductions made in this report, while giving valuable suggestions for improved methods of statistical research on these lines.

## TYPHOID FEVER IN MERTHYR.

WHENEVER there is an outbreak of typhoid fever in the mining districts of the midlands or of the north of England it is nearly always found to be more or less associated with the method of disposal of excrement that prevails in the particular locality affected, and it is even sometimes suggested that the substitution of water carriage for conservancy would put an end to these epidemics of enteric fever. That this view is not altogether borne out by experience elsewhere is shown by the only too frequent outbreaks of typhoid fever in the densely populated colliery districts of South Wales where water carriage is all but universal. During the whole of the present year Merthyr, which has a population of about 75,000 persons, has never been free from the disease and up to the middle of September there were as many as 214 cases notified. In the first half of the year the death-rate was equal to 0·5 per 1000 per annum or double the rate that was recorded in the adjoining districts of Aberdare and Rhondda and two and a half times more than the typhoid fever death-rate recorded in England and Wales in 1899. It is now more than 30 years since a sewage farm was established at Merthyr and the filthy privies and middens so common in the north of England are noticeably absent from the town; there are two fever hospitals and an abundant supply of water has been provided by the council who are even now enlarging their gathering grounds. But the Merthyr Council, like so many other sanitary authorities, appears to imagine that having completed such large undertakings as these their responsibility ends, forgetting that one of the most important duties imposed upon them by the Public Health Acts is to seek out and remedy by constant inspection of their district any insanitary conditions that may exist. The neglect of this duty has probably much to do with the present outbreak of typhoid fever in the town. The newly-appointed medical officer of health, Dr. C. E. G. Simons, will find himself altogether handicapped unless he is thoroughly supported by the members of the council in taking necessary action against individual property owners

and unless he is provided with a sufficient staff of competent inspectors to carry out frequent house-to-house visitations.

## THE SMOKE NUISANCE.

THE Metropolitan vestries must be fast asleep again judging from the undoubted recrudescence of the smoke nuisance during the past few weeks. We beg to stir them up once more. We have observed several chimneys in the immediate neighbourhood of THE LANCET Offices emitting dense volumes of black smoke and the nuisance proceeds on all sides with the most consummate disregard of the Public Health Act. We will point out the exact sites where the offence is committed if desired. Nor is the offence intermittently committed but continuously for days and weeks. What has become of that excellent movement, the Coal Smoke Abatement Society, so ably backed by Sir William Richmond with the view of stirring up the vestries to their sense of duty in this matter? Several chimneys in the Strand district and "over the water" have been pouring forth black smoke during the whole of the lovely weather which we have fortunately been experiencing this September. The days have been delightfully bright and the atmosphere particularly clear, only to be besmirched by persons who impudently commit this offence and in brazen defiance of the law. It is monstrous. Perhaps the vestry officials are away on a holiday. If so, the sooner they return the better, that they may chasten their deputies for what they have neglected to do and take action themselves immediately to suppress the evil.

## LOCAL AUTHORITIES AND ISOLATION HOSPITAL ACCOMMODATION.

A MEMORANDUM has just been issued by the Local Government Board on the provision of isolation hospitals by local authorities. In the main it follows the lines of the memoranda on this subject which have been issued by this department in past years and which have already done much to aid the satisfactory construction of isolation hospitals throughout the country. The advantages to every sanitary district of possessing a properly equipped hospital in readiness to meet emergencies are first set out. When isolation hospitals were novelties to the public more was no doubt claimed for them by some of their advocates than would now be admitted in view of the large practical experience since gained, and also of the better knowledge which we now possess of the multifarious ways in which infectious diseases may spread otherwise than by direct human intercourse. Nevertheless, the arguments in favour of these hospitals are very strong. That which perhaps appeals most to the public is touched upon in the memorandum, namely—the insurance which an isolation hospital affords against troublesome and prolonged interference with the business occupations of persons in whose households infectious sickness occurs and who are unable in most cases to arrange for adequate isolation in their own homes. There is no need, however, at this date to labour any points such as this. The isolation hospital has in this country come to be looked upon as essential to the satisfactory sanitary equipment of a local authority. No district that has set up an isolation hospital has ever, so far as we know, dreamt of abandoning it. The memorandum in question sets out the various points which the Local Government Board require to be complied with if the hospital is to be a permanent building erected out of money raised by loan. No definite proportion of beds to population is laid down, although one bed per 1000 is hinted at, where ward blocks are sufficient in number. A site of sufficient area to permit of future extension is advised; it should not, "of course," be in a very populous neighbourhood. In the case of small-pox hospitals the Local Government Board refuse to sanction a site which has within a quarter of a mile of it "either a hospital or a workhouse, asylum, or any similar establishment, or a population of as many as 200 persons," or within half a mile of it "a population of as many as 600 persons, whether in one or more institutions, or in dwelling-houses." These limits are the same which have been insisted upon by the Local Government Board for some years past in view of the demonstrated ability of small-pox to spread round small-pox hospitals. Precautions against aerial spread of this disease are clearly desirable. But rigid application of the above limits, as, for instance, if a suitable site has to be rejected because it happens to be 420 yards and not 440 yards from a cottage hospital, seemingly might in some cases involve considerable hardship. A plan is given showing a typical arrangement of blocks on a small site—an administration block, a ward pavilion, an isolation ward block, and a laundry and mortuary block. The administration block "should contain quarters for the matron or caretaker, and a sufficient number of bedrooms for the nurses and servants who will be required to work the hospital when in full operation"—a most desirable requirement seeing how administrative quarters of hospitals are apt to become overcrowded during epidemics. It is advised that ward blocks should be one-storey buildings save in large hospitals or in exceptional cases. Day rooms for convalescent patients are not suggested. The minimum requirement of air space per bed is 2000 cubic feet and of floor space 144 square feet. The hospital is required to be surrounded by a wall or close fence at least six feet six inches in height. This regulation applies to hospitals in isolated country places as well as to those situated near to centres of population. In isolation hospitals of the former character in Scotland these high walls, which on account of their expense and somewhat forbidding appearance have drawbacks as well as advantages, are, we believe, generally dispensed with.

## THE NOTIFICATION OF PLAGUE.

THE sanitary authorities of London have issued a circular, in accordance with an Order of the Local Government Board, informing all legally qualified medical practitioners that henceforth Section 55 of the Public Health (London) Act, 1891, under which small-pox, cholera, diphtheria, membranous croup, erysipelas, scarlet fever, and the fevers known as typhus, typhoid, enteric, relapsing, continued, and puerperal are notified, will include the disease known as plague and that it will be the duty of practitioners as soon as they become aware that a patient is suffering from this disease to send notice thereof to the medical officer of health at his office. It is sincerely to be hoped that no occasion will arise for testing the diagnostic powers of the medical practitioners of the country in regard to this disease. It is undoubtedly difficult for a practitioner to diagnose a disease which he has never seen. The best advice which we can give to our readers on this point is to recommend them to read carefully the reports of the Glasgow cases which we have been able to publish in recent weeks. Even if there be no further extension of the disease the perusal of them will still prove highly instructive and interesting, and if unhappily cases should arise they will be more quickly discerned by those who have thus studied the chief points of actual cases.

## A RARE MONSTROSITY.

IN the September number of the *Maryland Medical Journal* Dr. H. G. Beck of Baltimore gives a description, with two illustrations, of a fœtus which was born on Feb. 3rd, 1900, at the end of the seventh month of the mother's third pregnancy. Her first labour (May 13th, 1898) was strictly normal and at full term: the child is still living and every

feature is perfect. The second was a miscarriage in the fourth month, the fœtus showing no signs of malformation. There was positively no evidence of maternal impression during the third pregnancy. The child was still-born: the presentation was not ascertained on account of hydramnios and sudden spontaneous delivery. The specimen, which has been placed in the museum of the College of Physicians and Surgeons in Baltimore, presented all the combined features of harelip, cleft palate, acrania, hydrencephalocele, and spina bifida. It was a female, it weighed 219 grammes (seven and three-quarter ounces), and measured 27 centimetres (10¾ inches) in length and 24 centimetres (9½ inches) in circumference of the body. The most striking condition was the absence of the cranial portion of the frontal and parietal bones. The eyes formed the uppermost part of the head and stood out prominently. The nose was broad and distinctly flattened. The neck, it might be said, was entirely absent, the head being attached directly to the body. The hydrocephalic brain and the cord and their membranes were exposed and unprotected by osseous structure. The brain had two distinct hemispheres separated by the longitudinal fissure, and its general contour and outlines very nearly approached the normal. The foramen magnum was entirely absent. The vertebral arches were deficient from above downwards as far as the lower dorsal region. The rest of the body and the extremities were apparently normally developed.

## OPEN CABS.

WHY is it that London is not supplied with open cabs? Every provincial seaside town has its "fly," a conveyance which is a fairly respectable kind of well-upholstered landau very comfortable to ride in and certainly more commodious than that not particularly smart vehicle the London four-wheeler or "growler." From the point of view of health there can be no doubt also of the advantage of the "fly" and more especially, of course, when the weather permits the "fare" to ride in the open. The fact that the "fly" is more often open than not renders it also a more wholesome vehicle to ride in. Closed cabs are undoubted sources of infection, microbes infest the cushions and the mats on the floor, and the air might easily contain pathogenic organisms left by a previous "fare." On the contrary, the fresh air to which the "fly" is exposed renders its equipments fresh and wholesome, while infected air could not possibly linger. The closed cab, be it hansom or four-wheeler, is frequently "smelly" and "stuffy," for the simple reason that Nature's powerful cleansing agents, light and air, are excluded from purifying the interior. Again, persons of a decidedly nervous temperament would invariably choose the "fly" to ride in rather than the hansom. As to the latter vehicle, it is a sort of death-trap in wet weather when the "fare" is completely inclosed, as it were, in a shut-up box owing to the window fitting closely on the apron, which makes it nearly impossible for him to release himself in emergency, to say nothing of the possibility of being guillotined by the down-coming window. Even when the hansom is not closed it is a risky vehicle from the fact of the "fare" having to get in and out between the wheel and the horse's hind legs. On the other hand, the "fly" is a much more safe and commodious vehicle, offering every comfort, being easy to get into and out of, and if need be it can be closed, as in wet or cold weather, without much trouble. The "growler" is, of course, practically always closed—a fact, we think, which is hygienically objectionable. We urge the claims in favour of the "fly" over the hansom and four-wheeler, not only, however, on distinct hygienic grounds, but because we consider it to be a more acceptable vehicle than the London cab, be it hansom or four-wheeler, from every point of view. Why, then, again we ask, is it that London is the only town where such vehicles are never in evidence? At seaside and provincial towns, and some suburban places, the "fly" plies for hire both in summer and winter. We should welcome heartily any movement to bring about this very desirable reform in the manner of metropolitan travelling.

THE one hundred and twenty-eighth session of the Medical Society of London will commence on Monday, Oct. 8th, when an address, entitled, "The Romance of Surgery," will be delivered by the incoming President, Mr. John H. Morgan. The Lettsomian Lectures will be delivered in March and April by Dr. Mitchell Bruce, and the Oration in May by Mr. F. Richardson Cross.

THE death is announced of Miss Margaret Stokes, the distinguished Irish antiquary. She was a daughter of the late Dr. William Stokes, and consequently a sister of the late Sir William Stokes, who died in South Africa on August 18th. Miss Stokes was well known for her valuable work upon Celtic Christian Antiquities.

THE Old and Present Students' Dinner, Faculty of Medicine, University College, London, will be held at the Hotel Cecil on Monday, Oct. 1st, at 6.30 P.M. for 7. Dr. G. Vivian Poore will occupy the chair.

THE introductory lecture at the Royal Veterinary College will be delivered by Professor McFadyean, M.B., B.Sc. Edin., M.R.C.V.S., on Tuesday, Oct. 2nd, at 12 noon.

Mr. A. A. Bowlby and Mr. Cuthbert Wallace have returned to town after nine months' service in South Africa with the Portland Hospital.

# THE EXTEMPORANEOUS AERATION OF LIQUIDS.

APART from the question as to why it is that effervescing liquids prove so attractive, it is a fact that the demand for carbonated waters or mineral waters has increased enormously of late years. The mineral-water industry is comparatively a recent creation and it is one of great importance when it is considered that aerated waters form a very large proportion of the water used for drinking purposes by the community. Effervescence is a quality in beverages that is much sought after and undoubtedly the presence of an excess of carbonic acid in a beverage modifies the taste of that beverage in a very important way which is not altogether easy of explanation. The fact that there is movement in a liquid, or briskness, or, as it is sometimes termed, "life," may account for the attractiveness of effervescing fluids. But the attraction does not rest with the bubbling appearance of the aerated drink. An effervescing liquid seems also more attractive to the palate and more acceptable to the stomach than a still liquid. Carbonic acid gas in solution is a well-known sedative to the gastric nerves and soda-water and champagne (especially iced) are known aids in obstinate sickness. The importance of the rôle, whatever it may be, that carbonic acid fulfils in an aerated beverage can hardly be exaggerated when it is generally accepted that champagne without its gas loses for the most part its exhilarating qualities and soda-water loses its palatability and refreshing qualities when it has become flat.

The idea of artificially charging water with an excess of carbonic acid gas owed its origin probably to the fact that when sugary solutions or grape juice were allowed to ferment in closed vessels a sparkling liquid resulted. The operation, of course, required time. It was soon discovered that water could be made sparkling almost instantaneously by placing

it under carbonic acid gas at a considerable pressure and then bottling the liquid without removing this pressure. Nature herself has provided in many parts of the world waters supercharged with carbonic acid gas, but obviously the quantity of gas contained in these natural waters at the surface does not exceed more than their own volume, since under one-atmosphere pressure one volume of water takes up its own volume of gas, the volume retained in solution depending exactly upon the pressure under which the water is placed. The law on this point, stated briefly, is that the volume of carbonic acid gas contained in a water varies directly with the pressure to which it is exposed. Thus under one-atmosphere pressure water would contain its own volume of gas, under two-atmospheres pressure it would contain twice its own volume of gas, and so on. Accordingly by measuring the pressure of the gas in a bottle of soda-water it is easy to ascertain what quantity of gas is present in the liquid. The average pressure of most aerated waters is about four atmospheres, so that the water contains four times its volume of carbonic acid gas, three of which would be gradually discharged, producing effervescence on releasing the cork and exposing the liquid to the pressure of the air, and one of which would remain.

Several methods have been suggested for producing aerated water and many ingenious bottles have been contrived for preserving the water so prepared. As a rule most people are content to leave the preparation of aerated waters in the hands of the aerated water factor. Attempts, however, have been made from time to time to provide a small apparatus which would suffice to keep any ordinary household supplied with a quantity of aerated water made on the spot. The "seltzogene," for example, is a closed apparatus in which several pints of water may be aerated by placing in an upper chamber situated over the reservoir containing the water a mixture of tartaric acid and carbonate of soda which when moistened evolves carbonic acid gas, which slowly impregnates the water below and renders it effervescing. The simplest of all methods, however, of obtaining an effervescing water is to dissolve first an acid in the water and then to add a soluble carbonate such as carbonate of soda or *vice versâ*. But this method, of course, leaves a salt in solution which is a product of the interaction of carbonate of soda and tartaric acid and which renders the water unsuitable and unpleasant. Both methods of the extemporaneous aeration of water have recently been superseded by a much more ingenious arrangement.

We refer to the system known as Sparklets. This system has been before the public for some time, but its history has been progressive and the sparklets of to-day are a great advance upon the sparklets of some years ago. We remember when this system was shown as a novelty at a conversazione of the Royal Society. It then consisted of dropping a recently-pierced steel bomb containing liquid carbonic acid into a bottle of water of suitable size.[1] As we anticipated, there were obvious objections to this method, since the carbonic acid which impregnated the water soon attacked the steel bomb and produced an unsightly liquid due to the unstable nature of the carbonate of iron formed by the action of the gas upon the steel bomb. This defect of what promised to be an interesting system of aerating waters was, however, soon removed, and in view of the great improvements that have since been effected and of the fact that this method is being adopted very largely in the household for the extemporaneous preparation of aerated liquids we have deemed it a subject which from the public health point of view is worthy of independent investigation. The need for independent investigation of this comparatively new system becomes more apparent when we consider the question of impurities which such a system might possibly entail. We have therefore turned our attention chiefly to the following points in regard to the method of aerating waters by the extemporaneous means so easily afforded by sparklets: (1) the safety of the method arising from (*a*) the sparklet or bomb containing liquid carbonic acid gas or (*b*) of pressure in the charging bottle; (2) the purity of the gas; and (3) the purity of the finished product and its chances of contamination.

The elucidation of these important questions amounts in reality to a hygienic inquiry, and any investigation on these heads would not be complete without a reference, which must be brief, to the interesting methods by which "sparklets" are made and to the manufacture of the liquid gas which they contain. The raw material for the preparation of carbonic acid gas used in the sparklet is coke, which, from the productive point of view, is carbon. Coke, however, contains other things besides carbon, which produce on combustion gases which are not wanted for the purpose and which are objectionable in character. A process of complete purification is therefore adopted. The coke is first burnt in a furnace in the ordinary way with a good supply of air. The gases resulting on combustion, containing chiefly carbonic acid gas, are thoroughly washed or scrubbed before passing into a strong solution of carbonate of potash. Here the carbonic acid is absorbed and inert gases are excluded. The process is carried on until the carbonate of potash liquor is saturated. At this point it consists of bicarbonate of potassium or potassium carbonate with, so to speak, a loose molecule of carbonic acid gas. This super-carbonated liquor is then boiled and the excess of perfectly pure carbonic acid is thus expelled, any sulphurous or sulphuric acid that may have been absorbed from the coke gases being retained. The pure carbonic acid gas thus evolved passes into powerful compressing pumps which drive the gas into steel tubes in a liquid state where it may be kept until required. Or the gas direct from the bicarbonate of potash may be forced into gas-holders to be afterwards liquefied previously to the charging of the sparklets. The purity of the gas may be gathered from the following analysis which we made of the gas contained in a sparklet:—

| | | |
|---|---|---|
| $CO_2$ | ... ... ... ... | 99·75 per cent. |
| O | ... ... ... ... | 0·05 ,, |
| N | ... ... ... ... | 0·20 ,, |

We very thoroughly tested the gas for traces of impurities such as sulphur dioxide or carbon monoxide, but we did not obtain the slightest experimental evidence that even in infinitesimal quantity such gases were present. As the above analysis shows the carbonic acid gas amounted to 99·75 per cent., while the difference from 100 is accounted for by the presence of traces of air.

The sparklet originally consists of a steel disc which is beaten into small shallow cups and finally into a small steel bottle provided with a somewhat wide neck, to which, after the liquid has been forced into the bomb, a steel cap is attached and made tight by means of a washer at the same operation of filling. The liquid carbonic acid is forced into the sparklets under a pressure of 60 atmospheres. The sparklets are, however, tested to stand the pressure of 500 atmospheres. They are further tested by being immersed when fully charged in water at 60° F., which is afterwards raised to 150° F. The precautions taken to secure sparklets of absolute uniformity in regard to capacity and weight are very remarkable and commendable, and such, indeed, as ensure the sparklet being quite safe. The sparklets, in fact, are every one of them standardised by means of a most ingenious apparatus before they pass into the hands of the person who fills them with liquid carbonic acid. The sparklets are again weighed after the filling process so that the exact amount of carbonic acid which they contain is known and controlled. In this way both an excess of gas which would be dangerous is avoided and an insufficiency is prevented which would fail for the purpose of complete aeration. We have taken several sparklets of the No. 2 size at random and we have found a remarkable uniformity in the weight of carbonic acid gas contained in them. The variation was so slight as to be quite negligible and unimportant. The maximum weight of carbonic acid in one bomb was found to be 4·417 grammes and the minimum weight 4·402 grammes. These quantities approximate to four and one-fifth pints of carbonic acid gas when measured at the average temperature of 15° C. The capacity of the bottle for which this sparklet is made we found to be exactly one pint. Thus the aerated water would be under four atmospheres pressure and contain four volumes of gas. This is approximately the pressure of ordinary machine-made soda-water, which suffices for all practical purposes. We have further examined sparklets containing a mixture of oxygen and carbonic acid gases so that the water, if desired, may be aerated with some amount of oxygen as well as carbonic acid. These sparklets are suitable for the 12-ounce bottle. On analysis the gas contained in them showed the following composition:—

| | No. 1. | No. 2. |
|---|---|---|
| Carbonic acid | ... 73·54 per cent. | ... 77·60 per cent. |
| Oxygen | ... ... 7·46 ,, | ... 7·00 ,, |
| Nitrogen | ... ... 19·00 ,, | ... 15·40 ,, |

[1] THE LANCET, May 9th, 1896, p. 1307.

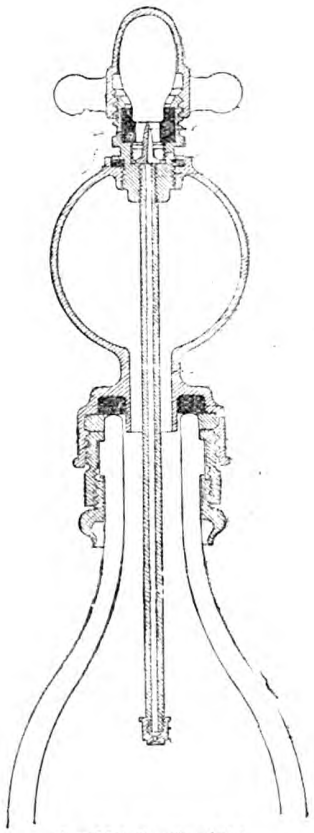
The presence of oxygen seems, however, to interfere with the complete aeration of the water by carbonic acid gas, although oxygen does undoubtedly soften the "sharpness" of taste of artificial carbonated water in general. It will be seen that the gases contain an important amount of nitrogen which is very sparingly soluble in water even under high pressure. Doubtless if the nitrogen were quite eliminated the aeration with the mixed gases would be more satisfactory.

FIG. 1.

Sparklet bottle with lever stopper.

Having described in some detail the accurate manner in which the sparklet is made and filled, and having recorded also the facts that the amount of gas in the same-sized sparklet varies within quite negligible limits and that the carbonic acid gas is as pure as it is possible to be, we may next consider the manner in which the extemporaneous aeration of water is effected by the sparklet. The aeration may be performed in a simple bottle as shown in Fig. 1 or in a bottle provided with a syphon tube (Fig. 3). The construction of the bottle and the charging tube is best explained in Fig. 2. The sparklet is placed in position just above the metal globe and just over a fine steel point. The neck of the sparklet placed downwards fits into a rubber washer. The bottle is then nearly filled with water and the charging apparatus attached by means of a screw so that the

FIG. 2.



Sparklet charging tube.

tube which delivers the gas just dips under the surface of the water. The screw cap at the extreme top of the apparatus is then screwed on, just covering the sparklet. The sparklet is thus brought to press upon the steel point, and carbonic acid gas escapes gently and uniformly and passes down the dip-tube through the water. A little shaking in order to facilitate the assimilation of the gas by the water completes the operation. It may be done in a few minutes and still water may be converted into aerated water within this time. Of course the result is better if time is allowed for the gas to dissolve in the water. We have noticed no evidence of risk attending this operation. It will be seen that the top of the charging tube contains a metal sphere which renders the carbonating process quite safe, this space sufficing to act as a cushion for the released gas, resistance being equal in all directions. As a further precaution the bottles are enclosed in a wicker cage. As a matter of fact, however, there is practically no record of bursting having occurred with the new form of sparklet bottle. Further, very great care is taken—and we have satisfied ourselves of this by inspection at the factories—to submit all bottles to a very severe pressure test which largely exceeds that which could ever obtain in practice even in the tropics. In these severe tests the proportion of bottles that fail to satisfy the examiner is exceedingly small and bursting is very rare indeed. The sparklet bottle is provided with a lever stopper attached to the neck of the bottle, so that if only a part of the contents is used the rest may be tightly corked and secured against getting flat or insipid by thus locking in the gas.

The sparklet syphon is a very ingenious arrangement. It holds about twice the quantity of water that the large-sized bottle does—that is, about two pints. Two sparklets of large size are used for the aerating operation. The construction of the sparklet syphon will be clear from a glance at Fig. 3. To obtain a syphon of soda-water aerated by the sparklet system the following is the procedure. First the bottle is nearly filled with water through a stopper at the side, and the stopper is replaced. There is a red mark on the shoulder of the bottle which defines the quantity that may be put in. Next a large sparklet is placed in position over the central tube and screwed gently down by means of the lever key. As with the ordinary sparklet bottle gas is discharged into the syphon, and by regulating the screw one way or the other the charging may be conducted with perfect uniformity and regularity. It is better to shake the syphon as the successive additions of gas are made. The quantity of gas discharged is under complete control and the operation can be done easily, as it should be, in instalments. As soon as the first sparklet ceases to discharge any further gas it is taken out by releasing the screw and a second sparklet is put in position in its stead and the same operation is repeated. There is no escape to speak of on the removal of the first sparklet since the valve opens inwards. The second sparklet is not removed until the syphon is empty. On the exhaustion of the second sparklet the lever key is made to take several turns until it rests on the edge of a metal gallery. At this point it becomes the lever of the syphon lifting the valve on depressing the key. The aerated water then escapes as with the ordinary well-known soda-water syphon. We have experienced no difficulty in producing in this way a syphon full of pure bright sparkling water. The convenience of the sparklet method of aerating waters is particularly manifest in the case of the sparklet syphon. We may add that the sparklet syphons are submitted to the same severe tests in regard to the pressure which they will stand as are the ordinary sparklet bottles.

FIG. 3.

Sparklet syphon.

The question of possible metallic contamination is one, of course, which must not be overlooked and we have made some definite experimental investigation upon this important point. To begin with, assuming that there is any prolonged contact of the carbonated water with any of the metallic fittings of the sparklet, these fittings are throughout coated with tin so that there is not at any part of the apparatus any metal which would form an injurious salt with the carbonated water or which would contaminate the water. While on this subject we may instructively refer to the experimental work of THE LANCET Special Analytical Commission on Mineral Water Machinery and Metallic Contamination. In this report, which was published in THE LANCET of Jan. 7th, 1893 (p. 43), it was shown that water saturated with carbonic acid gas under pressure easily dissolved lead, copper, zinc, and iron, but not tin. Since, then, the metallic fittings of the sparklet apparatus are effectively tin-lined it is difficult to see how any objectionable metallic

contamination of the water could take place. The only point of the sparklet apparatus likely to be attacked would be the dip tube which, however, is also tin-coated, but if stout capillary glass tubing could be substituted it would undoubtedly be an advantage, for the strain put upon metallic fittings by carbonated water is severe, especially when the metal is immersed for a long time. This question requires, however, very careful inquiry and we have made a series of experiments with the view of ascertaining whether in the sparklet any metallic contamination of the water took place. The results obtained leave little doubt that the water aerated by the sparklet method is free from metallic impurity. Occasionally slight traces of iron, however, were found in the water, due probably to the steel bomb, but never any poisonous metal. The presence of iron in small amount in carbonated water, though not objectionable from a hygienic point of view, makes the water unsuitable for admixture with wines or spirits or any beverage containing traces of tannin. Iron was never found in aerated water freshly made by the sparklet system or in water which was several days old, but only in aerated waters which were left to stand for weeks in the sparklet apparatus in order to make the test as severe as possible.

Obviously the easy extemporaneous aeration of liquids as afforded by the Sparklet system introduces a very wide field of application. By means of this system the aeration of all liquids may be easily effected and without any dilution. Milk, for example, can be charged straight away with carbonic acid gas without any addition of water at all, and undiluted aerated milk has been found to be an excellent beverage and food for invalids, especially where an irritable condition of the digestive functions exist. The sparklet, too, may be used for aerating wines without dilution or for making wine brisk which has become flat. To some extent the system of aeration by sparklets ensures the purity of the sparkling beverage, for the consumer can choose a special supply of water or other liquid of ascertained purity of character for the purpose. For transport purposes and for people in isolated parts of the world the sparklet system has proved invaluable, since it obviates the carriage of the water in aerated form; the water on the spot can be readily aerated by means of the sparklet apparatus. Lastly, the system of sparklets affords a ready means of preparing alkaline waters or waters containing mineral ingredients corresponding in character with those present in medicinal springs. Thus tablets are supplied for use with sparklets which when dissolved in the water subsequently aerated produce potash-, lithia-, or soda-water, or liquids approximating to the composition of Seltzer, Carlsbad, Vichy, and Malvern waters. As is well known an effervescent water affords a very agreeable way of administering these medicaments. Another interesting application of the sparklet system, and an important one for hospital purposes or for the sick room, is that iced carbonated water may easily be obtained by placing powdered ice in the bottle before charging. This method obviates the placing of the ice in the water after it has been aerated, which generally displaces a good deal of dissolved gas and tends, therefore, to render the liquid flat and insipid. Similarly syrups may be readily aerated; lime juice, lemon juice, &c., and a number of "fruit drinks" are prepared for the purpose.

The following are the conclusions to which we are led in regard to the sparklet system of aerating liquids by the experiments already cited:—1. The system is safe in view of the great care that is taken to test every essential part of the apparatus and carefully to gauge the amount of gas in the steel bombs before they are sent out of the factory.[2] The liability of bursting of the sparklet apparatus is no greater than in the case of the ordinary bottle or syphon of carbonated water. 2. The carbonic acid gas is very pure. 3. There was no evidence obtained that the system introduces any element of risk in regard to metallic contamination. 4. The system is easily understood and affords a simplicity of procedure in order to obtain a satisfactorily aerated beverage. 5. The system is applicable to the aeration of special liquids containing a standard quantity of drugs, in which case the suitability of the medicated water should be referred to the medical man. 6. Since the choice of water or liquid is left to the consumer some security can be obtained by this system as to the purity of the aerated drinks so prepared.

[2] Should a sparklet be exposed to excessive pressure either the washer would give way or the little cup be blown out, permitting the gas to escape in a comparatively harmless way. The safety of the sparklets for carriage and storage has been demonstrated by Professor Boys, F.R.S., and others.

## ANNUAL REPORT FOR 1899 ON BIRTHS, DEATHS, AND MARRIAGES IN IRELAND.

BY the courtesy of the Registrar-General for Ireland we have been favoured with the thirty-sixth annual report for the year 1899. This is the first report that has been issued from the Irish Register Office since the untimely death of Dr. T. W. Grimshaw, C.B., who for very many years discharged, with great distinction to himself and to the entire satisfaction of his medical brethren, the duties of the office which have since fallen to Mr. Robert Matheson. The report for 1899, which, like previous issues, appears within a reasonable period of the close of the year to which it relates, is drawn up mainly on the same lines as those of the late Registrar-General. There are, however, certain additions and improvements in the present volume which have been introduced apparently for the first time, and to these we shall draw attention presently. According to the table on the first page the birth-rate in Ireland has scarcely changed since 1889; it was 22·9 last year, and differed from the average in the previous 10 years by only 0·1 per 1000. The marriage-rate was also very low, being only 4·9 per 1000 in 1899, but this is a trifle higher than the average rate in 1889–98. The report shows that the proportion of emigrants stated to have left one or other of the Irish ports was greater last year than in any year since 1895. The mortality from all causes last year was so low as 17·6 per 1000 living; it was the same in both sexes, and was slightly lower than the average rate in the previous 10 years. It appears to be customary in Ireland that a relatively large number of the population should die in union workhouses; this is especially noteworthy in Leinster and in Munster, where the proportion of the total deaths that are registered in workhouses is as high as 14·2 and 16·1 per cent. respectively. In this report we notice a new diagram (No. 2) which shows graphically the proportion of the total mortality that is due to the chief causes. This diagram is very instructive; it indicates at a glance the commoner causes of death that were most fatal and those that were least so in Ireland in the year 1899. We would fain see a similar diagram in the reports of the English Register Office. Among the ordinary infectious diseases, both typhus fever and typhoid fever seem to retain their hold very persistently on the Irish people: 117 deaths from the former disease and 890 from the latter having been registered in the year 1899; both these numbers, however, are considerably below the average. Influenza again became epidemic towards the close of 1899, and although not so fatal as in the year 1893 it nevertheless caused 1716 deaths in 1899, which is considerably in excess of the average. In passing from a consideration of the general and zymotic mortality to that of the mortality from tuberculous disease we notice an irregularity which might readily lead to misconception and which therefore we hope to see remedied in future reports from the Sister Isle. Whilst the general and the zymotic death-rates are stated in proportion to 1000 persons living we find that the mortality from tuberculous disease is stated in one paragraph as so many per 1000 and in the next paragraph as so many per 10,000 of the population. Rates are frequently calculated per 1,000,000 or per 100,000 of the population with the object of avoiding decimals, but there surely can be no object in giving the rates per 10,000 living, for in that case fractions would still be required, and they are actually given in the report before us. In England the rates are calculated either per 1,000,000 or per 1000 of the population. The plan is to be commended on many grounds, and we should be glad to see it adopted elsewhere. Opposite page 16 is given a map which shows by means of different colours the variations in the mortality from tuberculous disease in each of the Poor-law unions of Ireland. From this map it appears that in three only of the unions were the deaths from this cause less than 1 per 1000 of the population. In 83 unions the rate was under 2 per 1000, in 17 it was under 4 per 1000, in two it was under 5 per 1000, and in two it was over 5 per 1000. As is the case in England,

tuberculosis is more prevalent in the urban than in the rural districts of Ireland. Thus we find that although in the latter the mortality was considerably less than 1 per 1000, it was as high as 4·6 in Cork and Belfast and amounted to 5·7 per 1000 in the south and to 6 per 1000 in the north of Dublin city. Of the total deaths from tuberculous disease about five-sixths were caused by phthisis, the residue being referred to tuberculous meningitis, tabes mesenterica, or to "scrofula," with other forms of tuberculosis. The deaths from malignant disease in 1899 were in the proportion of 0·59 per 1000 living; they were considerably more numerous among females than among males. During the 10 years 1889–98, with one exception, there was a continuous increase in the mortality from these diseases. An instructive table will be found at page 19, showing the parts of the body invaded by cancer and also the rates of mortality at the various groups of ages. From this table we see that of the 2654 deaths from malignant disease registered in 1899, 497 were referred to disease of parts of the head and neck and that of these more than two-thirds occurred in males. 636 of the classified cases were deaths from cancer of the stomach: 283 females died from cancer of the breast, and 174 from cancer of the uterus. As is the case in England also the mortality from cancer is low during the first 20 years of life, but from the twenty-fifth year onwards it increases steadily until at the age-period of from 65 to 75 years it kills as many as 364 in each 1000 living at that period. A noticeable feature in the Irish registration reports is the record of meteorological observations in Dublin for each month in the year. The observations are taken by Sir John W. Moore, president of the Royal College of Physicians of Ireland, at his house in Fitzwilliam-square West. For more than 20 years these observations have been recorded daily and the results have been published in the *Dublin Journal of Medical Science*. But in Ireland the close relation of meteorological conditions to public health was recognised at an early date and Dr. Grimshaw was not slow in obtaining Sir John Moore's permission to print his returns as an appendix to his own earlier reports as Registrar General of Ireland. In recent years the scientific value of these returns has been increased for comparative purposes by the addition of corresponding observations taken by Sir John Moore at his country residence in county Wicklow. The detailed observations and remarks of this distinguished meteorologist, continued as they have been for a long series of years, form an instructive and valuable appendix to the reports of the Irish Registrar-General.

## THE PLAGUE IN GLASGOW.

THERE is but little to add concerning the plague in Glasgow except that the number of cases has risen to 27.

In consequence of the appearance of plague in Glasgow and in view of the possible occurrence of cases in England and Wales the Local Government Board have issued an Order to sanitary authorities in "England and Wales (including London)." The Order applies as well to all vessels within the jurisdiction of a port sanitary authority or a riparian authority. The chief points of the Order are that plague is constituted a notifiable disease under the Notification of Infectious Diseases Act of 1899 and that sanitary authorities shall have the same powers and duties in relation to the notification of plague as they would have under Section 55 of the Public Health (London) Act, 1891, if plague were an infectious disease to which that section applied. Further, it shall be the duty of every medical officer of health to report to the Local Government Board any case of plague which may be notified to him or which may otherwise come or be brought to his knowledge and which may occur in the district or area assigned to his charge.

### CLINICAL ASPECTS OF THE CASES OF PLAGUE.

The following are some notes from Dr. A. K. Chalmers upon cases of plague occurring since Sept. 13th, and are explanatory of their association, so far as is known, with previous cases. Some of the cases were, it will be seen, also mentioned in our issue of Sept. 22nd:—

1. Mrs. B., aged 29 years, of 81, Cubie-street, who sickened on Sept. 13th, is the wife of a man employed in the sanitary wash-house, whose work consists in the disinfection of and removal of clothing from houses in which cases of plague have occurred. The result has been that we now insist on a bath and change of clothing after using clothing from infected houses. The use of overalls has been a matter of custom for some time, but these evidently do not afford complete protection.

2. A family named M. resided at 57, South Coburg-street. Mrs. M., aged 40 years, sickened on Sept. 16th: Mary M., aged 14 years, on the 13th; Robert M., aged 11 years, on the 15th; and Mrs. Margaret M., a daughter of Mrs. M., aged 20 years, who lived with her mother, on the 14th. All these persons formed one household, in which, as we were informed by neighbours, cases of illness had occurred. We find that these persons had an indirect association with the family T., of 23, Oxford-lane, and that on August 22nd a daughter of the family named Kate, aged 14 years, sickened, and died on the 28th, the cause of her death being certified as "pneumonia." The friends describe her illness as having been accompanied by painful swellings about the neck and arms.

In addition to the above, George H., aged 46 years, a boot top fitter, residing at 248, Mathieson-street, was admitted to the Belvidere Hospital on Sept. 14th, and died on the following day. He had been in association with a case provisionally regarded as ill-defined typhus fever, as explained below, which case, as the result of a post-mortem examination, has now been recognised as due to plague. George H. sickened on Sept. 7th. His illness was associated with sickness in a family named G., living at the same address. Mrs. G. was removed to hospital on Sept. 1st., and died on the 4th of suspected typhus fever, whilst her daughter at the time of her removal was discovered dead in their house. In Mrs. G.'s case the question of plague was considered, and the diagnosis was held in suspense until a post-mortem examination had been made, the result of which was inconclusive.

Since Sept. 19th no case of plague is known to have occurred among the population of Glasgow, the admission to the hospital on the 20th being that of a male patient from Govan who had been sent to one of the general hospitals for treatment for what was regarded as an affection calling for surgical care, and who was thence transferred to the Belvidere Hospital.

The following table continues the record of admissions into the hospital:—

| Name. | Address. | Sickened. | Removed to hospital. | Where exposed to infection. |
|---|---|---|---|---|
| (1) Charles McM. | 52, Dale-street. | Sept. 8th | Sept. 9th | Slept on a bed on which a neighbour had died from "pneumonia" on August 28th. Was buried on Sept. 1st. |
| (2) Rosina M. ... | 23, Florence-street. | August 23rd | ,, 10th | Worker in a hair factory; no known association with other cases. |
| (3) Mrs. B. ... ... | 81, Cubie-street. | Sept. 13th | ,, 14th | Wife of a clothes-collector in sanitary washhouse. |
| (4) Ellen R. ... ... | Belvidere Hospital. | ,, 13th | ,, 14th | Cleaner in plague ward. |
| (5) George H. ... | 248, Mathieson-street. | ,, 7th | ,, 14th | See note in text. |
| (6) Mrs. M. ... ... | 57, South Coburg-street. | ,, 14th | ,, 15th | A married daughter of Mrs. M. (No. 9), admitted Sept. 16th. |
| (7) Mary M. ... | ,, | ,, 14th | ,, 15th | See details in text. |
| (8) Robert M. ... | ,, | ,, 14th | ,, 16th | ,, ,, |
| (9) Mrs. M. ... ... | ,, | ,, 13th | ,, 16th | ,, ,, |
| (10) Mrs. G. ... ... | 52, Dale-street. | ,, 18th | ,, 19th | Sister and niece of C. McM. (No. 1). See note below. |
| (11) Mary G. ... ... | ,, | ,, 18th | ,, 19th | |
| *(12) William W. ... | 21, Robert-street, Govan. | ,, 1st | ,, 20th | — |

* Admitted through one of the general hospitals.

In addition to the above five persons were removed to the Belvidere Hospital during the fortnight, presenting symptoms which at the time of their admission gave rise to a suggestion of plague. In three of these cases the further development of the symptoms enabled them to be set aside as definitely not cases of plague, while two cases still remain under observation.

RELATIONSHIP OF CASES.

(1) Charles McM. has no association which can be traced with earlier known cases. A neighbour had died on August 28th from "pneumonia" and was buried on Sept. 1st. After the death the bed on which he had laid was transferred to McM.'s house and was used by McM. and his wife.

(2) Rosina M. sickened on August 23rd, a swelling in the groin being observed by herself on the 26th. She had no regular medical attendance and the nature of her illness was not recognised till Sept. 10th.

Cases in the above table numbered 3 and 6-9 are described on p. 964 (cases 1 and 2).

(4) Ellen R. is a ward-cleaner employed in the plague ward, who, like all the others whose work brings them into contact with these cases, received an injection of 10 cubic centimetres of Yersin's serum. This was on Sept. 3rd, and she sickened on the 13th, her illness being of the mildest possible description. The micro-organism has, however, been recovered from an affected gland.

(5) George H., aged 46 years, is a boot top fitter, residing at 248, Mathieson street. He was admitted into the hospital on Sept. 14th and died on the following day. At the necropsy his death was found to have resulted from plague. He sickened on the 7th. His illness was associated with earlier illnesses in a family (G.) living at the same address. Mrs. G. was removed to hospital on Sept. 1st and died on the 4th from suspected typhus fever, whilst her daughter at the time of her removal was discovered dead in their house. In Mrs G.'s case the question of plague was considered because she was known to have been a visitor at the house of the family B. where the earlier cases occurred, but the diagnosis was held in suspense. At the necropsy the evidence was still held as inconclusive.

(10) Mrs. G. is a sister of patient No. 1 and sickened under observation on Sept. 18th. On the 10th she had been given subcutaneously 10 cubic centimetres of Yersin's serum. She had a mild attack.

(11) Mary G., aged six years, a daughter of patient No. 10, also sickened on Sept. 18th. Because of her age and some passing indisposition an injection of Yersin's serum was not given. Her attack has proved fatal.

Putting these together with the earlier admissions we have now had a total of 27 admissions from definitely recognisable plague, and of these up to the present (Sept. 26th) five have died and 22 remain under treatment, one of these being a patient from the adjoining burgh (Govan).

MILD NATURE OF THE ATTACK IN MANY CASES.

Eight only of the cases coming under treatment in hospital can be classed as severe attacks, and of these five have died. Seven, on the other hand, are of extreme mildness so that save for their association with recognisable cases a suggestion of plague would scarcely have been raised. 12 fall into a middle class, the severity in individual cases ranging between the severe and the mild type just alluded to, but with a tendency to mildness rather than otherwise. With regard to many of the milder forms the question of diagnosis is no easy one. We are familiar in small-pox outbreaks with the extremely modified form which the disease may present in persons fairly well protected by vaccination, and where a definite history of exposure alone affords a means of interpreting aright symptoms which would indeed rarely be critically surveyed were the persons not under observation at the time. We are now learning practically that in a corresponding way plague can become so defaced by mildness in its form of attack that an administrative difficulty of no inconsiderable magnitude is created. Consequently I believe safety lies in disregarding the query which constantly haunts these milder forms and in dealing with the surroundings and associates of the suspect as if no doubt as to the nature of his illness existed.

YERSIN'S SERUM.

Over 60 persons known to have been in association with patients suffering from plague have been immunised by subcutaneous injection of Yersin's serum in doses of 10 cubic centimetres. Of these two have sickened with a very modified form of the disease. Questions of dosage and the method of administration will require consideration in the light of these partial failures. The serum is much more powerful as a curative agent when injected into the veins than when given subcutaneously, and it may be that the full protective value for "contacts" is only to be obtained by a similar selection of site.

DISINFECTION.

To the methods of disinfection formerly described we have now added a final gaseous disinfection of the house with formic aldehyde. When disinfection and cleansing is finished the windows of the house are left open.

---

In our issue of Sept. 8th we published "A Preliminary Note on the Outbreak of Bubonic Plague in Glasgow," wherein it was mentioned that Dr. Thomas Colvin and another medical man had been the first to see and notify the cases which turned out to be plague. The second medical man was Dr. C. E. Robertson.

---

# THE REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR 1898.

CONCLUDING NOTICE.[1]

BEFORE dismissing altogether the subject of the prevalence of enteric fever among our troops serving in India we may refer to a few of the facts and conclusions set forth in the report under review. In the section devoted to the native army there is a tabular statement which brings out in a very striking way the extremely low ratios of admissions and deaths from this fever among the native troops and jail population respectively as compared with those of European troops. Nor can this difference be attributed to one of diagnosis only, for the total fever mortality in the two armies is very different. Among the European troops 54 per cent. of all deaths in 1898 were from fevers, whereas they were only 16 per cent. among native troops. Seeing then that the death-rate of European troops was so much greater than that of native troops from all kinds of fever it seems to follow that the nature of the fevers cannot be the same in both cases and that native soldiers and prisoners are far less liable to enteric fever than are British soldiers. While there can be no doubt that this fever is water-borne, and that outbreaks of it are very frequently traceable to a contaminated water-supply, there is no reason why this should invariably be the case. At Quetta the disease prevailed with greater virulence in the year under report than in any other Indian station, but the catchment area is described is an ideal one and the water as above suspicion. We notice that Major A. M. Davies, R.A.M.C., whose training as assistant professor of hygiene at Netley specially qualified him for such an investigation, excludes water as a probable cause of the sickness at Quetta and has recourse to the aerial distribution by dust-storms of sewage-derived germs from badly-placed filth trenches as an explanation. It does not follow, of course, that because the presence of Eberth's enteric bacillus was not detected in the water the disease was not spread by its agency. The epidemic at Maidstone is a case in point. Not only have our ideas been greatly enlarged in regard to possible sources of infection, but the long-continued period over which the infection may extend in those who have suffered from an attack, as well as the fact that clinically the mildest cases of enteric fever may be just as virulent as the worst for spreading infection, have all tended to increase our difficulties in tracing out the sources of it.

The study of the scientific differentiation of the fevers of India (whether physical or microbic) from one another is being actively prosecuted and we know already that, in addition to enteric fever and fevers of a malarial type attributable to the malarial parasite, there are now good grounds for believing that Mediterranean (so-called Malta) fever also prevails in India. Still, enough has been said to indicate the state of uncertainty for all practical purposes that exists regarding our knowledge about the causes of the terrible prevalence of enteric fever in India. As Major

[1] The first notice appeared in THE LANCET of Sept. 15th, 1900, p. 832.

Davies remarks, water which has been boiled, if subsequently exposed to contamination by dust, is liable to become a very impure and dangerous water unless great care is taken in its storage. At page 28 of the Sanitary Commissioner's report under review there are some pertinent remarks on the difficulties attending the use of the Chamberland filter on military service owing to the too fragile nature of the bougies.

It must be confessed that any wholesale study, as it were, of the literature in regard to the etiology and causes of enteric fever is rather bewildering than otherwise to the practical sanitarian. The recognition of the bacteriological causes of disease has, no doubt, opened out a vast field and given precision to our investigations. But it has to be borne in mind that it is only when the results of such investigations have become sufficiently well established as to admit of being practically applied that the sanitarian is, officially speaking, warranted in recommending the expenditure of public money for that purpose. As regards preventive medicine it is mainly in the direction of personal protection by inoculation against infectious diseases that the most promising and successful attempts to avert or to eradicate an epidemic or to protect individuals have of late been made. The labours of Mr. Haffkine in regard to inoculation against plague and those of Professor Wright in respect of typhoid fever may be mentioned as among the most recent advances in this direction.

The army of India shared in the comparative immunity from cholera which characterised the year 1898 in India generally. The mortality from abscess of the liver in 1898 was 25 times greater among European than among native soldiers. On the other hand, the admission rate from dysentery among European soldiers was to the ratio of the native soldiers as 1 to 1·5, the relation being the same as in the two preceding years. Some interesting medical points and further particulars in connexion with dysentery and abscess of the liver are detailed at page 64 *et seq.* of the report and the matter was gone into at length in the Sanitary Commissioner's report for 18 4. In passing, we are tempted to inquire into the causes of these differences and whether the relative insusceptibility of the native to abscess of the liver can be attributable to differences of diet—such as the absence of alcoholic drinks and animal food in the case of the native of India.

As regards the prevalence of venereal disease in the army serving in India we are glad to notice that there was a decrease in the admission rate. Touching the diseases of the jail population, the predominant causes of jail mortality are bowel complaints, respiratory diseases, and tubercle of the lungs. Bowel complaints are very common and cause a very large mortality. As the Sanitary Commissioner remarks: "There would be little exaggeration in saying that the prevention of these complaints is the beginning and end of jail hygiene, as it certainly is the most difficult of the problems the jail medical officer has to face." The Sanitary Commissioner, comparing the rates of mortality of the different classes one with another, sums up the comparison as follows: The chief cause of deaths among European troops was fever, among native troops respiratory diseases, and among prisoners bowel complaints.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6356 births and 4041 deaths were registered during the week ending Sept. 22nd. The annual rate of mortality in these towns, which had declined from 21·7 to 18·2 per 1000 in the three preceding weeks, further fell last week to 18·1. In London the death-rate was 16·5 per 1000, while it averaged 19·2 in the 32 provincial towns. The lowest death-rates in these towns were 11·5 in Croydon, 12·3 in Bradford, 12·4 in Halifax, and 13·2 in Cardiff; the highest rates were 23·5 in Brighton, 23·8 in Hull, 24·3 in Salford, and 25·5 in Blackburn, in Sheffield, and in Sunderland. The 4041 deaths in these towns included 771 which were referred to the principal zymotic diseases, against 1422, 1143, and 879 in the three preceding weeks; of these 497 resulted from diarrhœa, 105 from whooping-cough, 72 from diphtheria, 50 from "fever" (principally enteric), 26 from measles, and 21 from scarlet fever. No death from any of these diseases occurred last week in Halifax; in the other towns they caused the lowest death-rates in Croydon, Birkenhead, Huddersfield, and Bradford; and the highest rates in Preston, Sheffield, Hull, and Gateshead. The greatest mortality from measles occurred in Swansea; from scarlet fever in Sunderland; from whooping-cough in Nottingham, Blackburn, and Gateshead; from "fever" in Bolton and Portsmouth; and from diarrhœa in Wolverhampton, Preston, Sheffield, Hull, and Gateshead. The 72 deaths from diphtheria included 30 in London, nine in Leicester, and seven in Sheffield. No fatal case of small-pox was registered last week in any of the 33 towns; and only two small-pox patients were under treatment on Saturday last, Sept. 22nd, in the Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1804, against 1702, 1736, and 1753 on the three preceding Saturdays; 269 new cases were admitted during the week, against 176, 213, and 243 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 124 and 161 in the two preceding weeks, further rose last week to 203, and were 30 above the corrected average. The causes of 40, or 1 0 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Salford, Newcastle, and in 14 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Manchester, and Sheffield.

### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·5 and 18·9 per 1000 in the two preceding weeks, was again 18·9 during the week ending Sept. 22nd, and was 0·8 per 1000 above the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 16·6 in Leith and 16 9 in Perth to 20 1 in Aberdeen and 22·3 in Greenock. The 584 deaths in these towns included 62 which were referred to diarrhœa, 20 to whooping-cough, 11 to diphtheria, seven to "fever" (including one fatal case of bubonic plague), five to measles, four to scarlet fever, and three to small-pox. In all 112 deaths resulted from these principal zymotic diseases, against 83 and 98 in the two preceding weeks. These 112 deaths were equal to an annual rate of 3·6 per 1000, which was slightly above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of diarrhœa, which had been 42 and 54 in the two preceding weeks, further rose last week to 62, of which 26 occurred in Glasgow, 11 in Edinburgh, nine in Aberdeen, and seven in Dundee. The deaths from whooping-cough, which had been 21 in each of the two preceding weeks, declined to 20 last week and included 16 in Glasgow. The fatal cases of diphtheria, which had been three, five, and six in the three preceding weeks, further rose last week to 11, of which three were registered in Edinburgh, three in Paisley, two in Dundee, and two in Greenock. The deaths referred to different forms of "fever," which had been four and seven in the two preceding weeks, were again seven last week and included three in Paisley and three (one of which was a death from bubonic plague), in Glasgow. The fatal cases of measles, which had decreased from 16 to two in the five preceding weeks, rose again last week to five, of which two occurred in Glasgow and two in Edinburgh. The deaths from scarlet fever, which had been four and seven in the two preceding weeks, declined again to four last week, and included three in Glasgow, where the three fatal cases of small-pox were also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 79 and 70 in the two preceding weeks, rose again last week to 101, and showed an excess of 37 over the number in the corresponding period of last year. The causes of 26, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 22·2 and 24 8 per 1000 in the two preceding weeks, declined again to 24·5 during the week ending Sept. 22nd. During the past four weeks the death-rates in the city has averaged 24·6 per 1000, the rates during the same period being 17 9 in London and

17·1 in Edinburgh. The 164 deaths belonging to Dublin registered during the week under notice were only two less than the number in the preceding week, and included 31 which were referred to the principal zymotic diseases, against 26 and 44 in the two preceding weeks; of these 24 resulted from diarrhœa, three from whooping-cough, three from "fever," one from diphtheria, and not one either from small-pox, measles, or scarlet fever. These 31 deaths were equal to an annual rate of 4·6 per 1000, the zymotic death-rate during the same period being 2·7 in London and 3·1 in Edinburgh. The fatal cases of diarrhœa, which had been 32, 20, and 27 in the three preceding weeks, declined again to 24 last week. The deaths from whooping-cough, which had increased from four to seven in the three preceding weeks, declined again last week to three. The deaths referred to different forms of "fever" showed a decline of four from the number in the preceding week. The 164 deaths in Dublin last week included 43 of infants under one year of age and 35 of persons aged upwards of 60 years; the deaths of infants showed a decline, while those of elderly persons exceeded the number in the preceding week. Three inquest cases and four deaths from violence were registered, and 40, or nearly one-fourth, of the deaths occurred in public institutions. The causes of 11, or nearly 7 per cent., of the deaths in the city last week were not certified.

## THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeon Charles James to the Cape of Good Hope Hospital. Surgeon E. T. P. Eames to the *Sans Pareil*.

### ROYAL ARMY MEDICAL CORPS.

The Secretary of State for War has offered nominations to the Royal Army Medical Corps to the following universities, colleges, and medical schools:—University of Aberdeen; University of Durham; University of Edinburgh; University of Glasgow; Catholic University of Ireland; the Mason University; Trinity College, Dublin; Queen's College, Cork; Queen's College, Belfast; Yorkshire College, Leeds; University College, London; King's College, London; Royal College of Surgeons in Ireland; St. Bartholomew's Hospital, London; St. Mary's Hospital, London; and St. Thomas's Hospital, London.

### VOLUNTEER CORPS.

*Royal Engineers:* 1st Durham: Surgeon-Captain F. W. Gibbon to be Surgeon-Major. *Rifle:* 3rd Volunteer Battalion the East Surrey Regiment: Surgeon-Lieutenant-Colonel W. A. F. Bateman resigns his commission, with permission to retain his rank and to wear the uniform of the battalion on retirement. 2nd Volunteer Battalion the Welsh Regiment: Surgeon-Major J. H. Davies resigns his commission, with permission to retain his rank and to wear the uniform of the battalion on retirement. 2nd Volunteer Battalion the King's (Shropshire Light Infantry): Surgeon-Major C. H. Gwynn to be Surgeon-Lieutenant-Colonel. 3rd London: The undermentioned officers resign their commissions:—Surgeon-Captain W. M. Abbot-Anderson and Surgeon-Lieutenant R. Fenner.

### TRANSVAAL WAR NOTES.

The following officers of the Royal Army Medical Corps have been discharged from hospital for duty:—Lieutenant S. G. Butler, Lieutenant H. F. Hart, Major H. D. James, and Captain G. A. T. Bray.

### SOME OF THE LESSONS OF WAR.

There is very little doubt that the experience acquired in South Africa, China, and in West Africa during the Ashanti campaign, will lead to many changes and modifications in the clothing and equipment of the army. If we may judge from the accounts received from China, where there has been an unusual opportunity of comparing the clothing and equipment of troops of the allied forces one with another, the khaki clothing of British troops is, on the whole, the best adapted for service in war. The reports at the end of the campaign in China should contain a large amount of useful and instructive information on a variety of practical points relating, among other things, to army hygiene and the field medical systems and arrangements followed by the armies of Russia, Germany, France, and Japan.

There is one thing to be feared perhaps, as a possible result of our campaign in South Africa, and that is that reforms and changes may be recommended which would be admirably adapted for fighting with the Boers in their own country but not by any means so well adapted for fighting elsewhere with trained and disciplined troops moving together on recognised military methods and in accordance with those strategical and tactical systems of scientific warfare which are recognised and followed by continental armies.

### ARMY MEDICAL SCHOOL, NETLEY.

The eighty-first winter session of the Army Medical School will commence on Monday, Oct. 1st. The session will be attended by 23 surgeons-on-probation who have gained entrance to the school by examination—nine for the Royal Army Medical Corps and 14 for the Indian Medical Service. The following is a list of the surgeons-on-probation who are entering the Army Medical School by examination:—

ROYAL ARMY MEDICAL CORPS.

1. H. J. McGrigor.
2. W. R. S. Goodwin.
3. J. H. Brunskill.
4. A. C. Duffey.
5. A. W. Gibson.
6. C. D. Myles.
7. R. N. Hunt.
8. H. E. Howley.
9. R. F. M. Fawcett.

INDIAN MEDICAL SERVICE.

1. C. W. Melville.
2. N. S. Wells.
3. R. McCarrison.
4. J. Masson.
5. W. Anderson.
6. W. D. Pringle.
7. E. H. B. Stanley.
8. W. H. Leonard.
9. J. G. G. Swan.
10. R. McL. Dalziel.
11. A. W. C. Young.
12. J. J. Robb.
13. S. A. Razzak.
14. R. B. B. Foster.

### THE BLANE GOLD MEDAL.

The Blane gold medals for medical officers of the Royal Navy have just been awarded to the undermentioned officers—viz., Staff Surgeon J. Macdonald Rogers, of H.M.S. *Terror*, and Surgeon Oswald Rees, Royal Marine Light Infantry, Walmer.

### DEATHS IN THE SERVICES.

Lieutenant-Colonel Michael Richard Ryan, Royal Army Medical Corps, aged 48 years, at Hong Kong on the 23rd ult. He joined the army in 1877 and reached the rank of Lieutenant-Colonel in 1897. He served in the Afghan war, 1878–70, including the advance through the Khyber Pass and capture of Ali Musjid (medal), and in the Egyptian war, 1882, including the battle of Tel-el-Kebir (medal with clasp and bronze star).

## Correspondence.

"Audi alteram partem."

## PARISH MEDICAL OFFICERS IN THE HIGHLANDS AND ISLANDS.

*To the Editors of* THE LANCET.

SIRS,—Now that the reply of the Local Government Board to our memorial for assistance from our parish councils to get an annual holiday has been received it seems to me an opportune time to expose the unfair and defective conditions under which we parish medical officers labour. I have been hoping the matter would be taken up by a more capable man than myself, but apparently no one will take the initiative. Having been a Poor-law medical officer for over 10 years, during which time my absence from the parish on holidays has reached the magnificent aggregate of six weeks (the parish minister's annual holiday), I feel a certain qualification for undertaking my self-imposed task. Our inability to get a much-needed holiday arises from two causes—want of money and the excessive fees charged by locum-tenents, fees which wealthy practitioners in the south can easily pay but which are quite beyond our slender means.

If we look into the matter we find that these Highland and island parishes are composed of very poor people from whom it is impossible for us to gain an income at all commensurate with our hard work and grave responsibilities, let alone make provision for old age, hence a retaining fee is needed to get us to reside in the parish. This retaining fee is simply a small salary given for attending and supplying medicines to paupers, fixed upon by a narrow-minded parish council

sanctioned by the Local Government Board, totally ignorant of the merits of the case and the onerous duties we have to undertake. Such salaries are the lowest possible sums of money offered to get a medical man to reside in the parish and out of all proportion to our parochial duties. This may seem strong language, but the time has surely come when reformation is needed in the relations existing between Poor-law medical officers, parish councils, and the Local Government Board. Improvement in our condition will only come to us by persistent, honest, and powerful combination among ourselves to a man, and I still have such belief in the profession generally that it will back us up. I know that several if not all the eminent men of our profession who have influence at headquarters will support our cause and work for us. I have been told that our parochial salaries are sufficient for attending the paupers. I say that the salaries given are nothing of the kind in order to allow us to do justice to them without being out of pocket. These poor wretches are scattered all over the parish, in many cases at great distances from our residence, and it is impossible for us to give them the medical attention they ought to receive without an enormous expenditure of time spent in travelling. Further, what about the number of poor people bordering on pauperism, often residing at long distances from us, whom we are obliged to visit and supply with medicines and never receive a penny for our services? The parish councils will not pay us, yet they require us to visit the different districts periodically so that poor people may have the advantage of our services on the cheapest possible scale. This is part of our work as the parish servant, yet our salary is only for attendance on paupers. This extra work we are compelled by common humanity to undertake, yet we never receive a penny extra from the funds of the parish. We are bound to become philanthropists and cannot help ourselves. I would here emphasise the distinction between being practically forced to give our services for nothing in very many cases and doing the same at our own discretion. When much sickness is prevalent our consulting-rooms become general dispensaries.

If we require an assistant in an operation on a pauper we have to pay him out of our own pockets. Is such a condition of things fair to us? Parish councils have no right to expect us to be Dr. MacLures. My contention is this—if the Local Government Board insist that these poor parishes have the luxury of a resident medical officer (ostensibly to attend paupers, of course) they should also insist that he is paid a sufficiently remunerative salary for his hard work and valuable services. It is absurd to expect that parish councils will take notice of the above facts if they can possibly evade them. Parish councils can easily afford to double or treble their contributions to our salaries (in many cases only about 10*s.* 6*d.* a week), and the Government could do the same, thus making the pay somewhat consonant with the work done. At present our position is that of a parish slave bound to attend all and sundry in all weathers, night and day, whether we are paid or not.

Again, we are absolutely at the mercy of these parish councils, frequently composed of local men, partially educated, and without that breadth of mind desirable in a body having power over men educated and brought up in a different sphere to themselves. They can turn us away without assigning a reason and the Local Government Board, bound hand and foot by red tape, tell us they cannot help us unless an Act of Parliament is altered. The sooner such one-sided Acts of Parliament are altered the better. I would ask that the Local Government Board have absolute control over us as to salaries, holidays, tenure of office, and payment for extra services. Were our position thus recognised and protected by Government it would give us a standing in the eyes of the public and an independence we cannot now enjoy. Further, we are expected and would really need to be *au fait* with every branch of our profession and keep ourselves supplied with up-to-date instruments which may never be needed for years. Yet how can we do so out of the slender hand-to-mouth incomes we are able to derive from these poor out-of-the-way parishes? We cannot attend post-graduate lectures, visit hospitals, study in anatomical museums, take in medical literature, and generally keep ourselves up to date like our brothers in the south. All these advantages are denied us on account of our isolated position, and we get rustier day by day and year by year. A minimum annual holiday of a month or six weeks would materially strengthen us professionally, physically, and mentally, and, in the words of the Local Government Board, "it would be to the advantage of the public" whom we serve.

We cannot meet to discuss what combined action may be taken, so I would request all parish medical officers who approve of my statements and have suggestions to offer to communicate with me. My proposal is to draw up a petition signed by every Poor-law medical officer in the Highlands and islands, have it printed, and copies sent to the Local Government Board, the General Medical Council, all the branches of the British Medical Association, every Cabinet Minister, and those Members of Parliament who are likely to support our claims, and I feel sure of a mitigation of our present condition, if not absolute success in our appeal. I feel I have only touched the fringe of the question in a very imperfect way, yet if I have aroused my colleagues to agitate in a business-like manner for better conditions all round I shall feel satisfied in the meantime.

I am, Sirs, yours faithfully,

HENRY PEARSON TAYLOR, M.B., C.M. Aberd.

Reafirth, Mid Yell, Shetland, Sept. 16th, 1900.

## "THE PRESENT POSITION OF PATHOLOGY IN ENGLAND."

*To the Editors of* THE LANCET.

SIRS,—I have read with great interest the letters by Dr. Powell White and Dr. F. Bushnell on the above subject which have recently appeared in THE LANCET and can cordially endorse all that they say. Pathology seems still to be regarded by many as a subject of merely scholastic importance, and practical pathology as an aid in diagnosis as work to be undertaken with confidence by anyone who can stain a section and look down a microscope; experience and thought are not required. The remuneration offered, therefore, is merely that of a mechanic. With regard to the work done by research societies in pathology I have come to the conclusion, after considerable experience, that the fee charged is in many cases not in excess of the value of the opinion given but rather the reverse.

I am, Sirs, yours faithfully,

York, Sept. 24th, 1900. P. J. CAMMIDGE.

## "PROFESSIONAL ORGANISATIONS."

*To the Editors of* THE LANCET.

SIRS,—"Magna est veritas" is my apology for this, positively my final, contribution on the subject of "Professional Organisations." It is absolutely untrue that I refuse to waive the fee in consultations with institute surgeons. The letters forwarded by Mr. Wyllys state, in language lucid enough for an infant school, my consent to any pecuniary conditions the committee think fit to impose, and my rejected resolution ignores fees altogether.

To Mr. Wyllys's question let me reply that never having been honoured with one-fifth of the club practice formerly enjoyed by him my feelings of reprobation are proportionately less acute. If the institute medical officers—after the lapse of years—still merit the reprobation on which Mr. Wyllys is so keen I would suggest that, at any rate, reprobation should fall short of vindictiveness. Moreover, it is impossible to injure the institute surgeon without at the same time injuring the institute patient by interposing obstacles to the quest for assistance until, maybe, it is too late.

Kindly permit me to quote a few words, facts, and inferences.

*Words.*—Mr. Wyllys states: 1. "In any really urgent case we are individually prepared to meet them (i.e., the institute doctors) when called upon to do so." 2. "We are, and always have been, prepared to give immediate help if called upon to the institute surgeon in cases of grave and sudden emergency."

*Facts.*—1. If the pleonasm "really" is omitted from Mr. Wyllys's first statement it is synonymous with my own proposition, yet the proposition is rejected. 2. No records exist of either of the statements being acted upon. 3. There is no denial that help from an institute surgeon has been accepted.

*Inferences.*—1. Cases of "real" urgency or "sudden and grave emergency" do not happen among institute patients. 2. If the latter have only ordinary chronic diseases, such as Bright's disease or diabetes, bronchitis or fibroid phthisis, they are not eligible for consultation while attended by the

institute surgeon. And this is common humanity. 3. Mr. Wyllys's statements are satisfactory as evidences of an awakening conscience.

It was very kind of Mr. Wyllys to postpone boycotting me yet a little longer. I am irresistibly reminded of the "Jackdaw of Rheims"—

> "Never was heard such a terrible curse.
> But what gave rise
> To no little surprise,
> Nobody seemed one penny the worse."

I will only add, Sirs, that when the wise medicine men of Yarmouth—mustering at an annual meeting six all told—have their sapient laws checked by a central authoritative body, then, and not till then, will I submit my sense of what is right and what is wrong to their infallible jurisdiction.

I am, Sirs, yours faithfully,

Great Yarmouth, Sept. 23rd, 1900. JAMES RYLEY, M.D. Lond.

## THE DETECTION OF LACTIC ACID.

*To the Editors of* THE LANCET.

SIRS,—I have read with much interest Dr. Shufflebotham's valuable contribution on "The Chemical Examination of Gastric Contents" in THE LANCET of Sept. 15th, and being interested more in the chemistry than the pathology of the question I beg to offer a remark on one point which seems to me to be not quite clearly expressed. I refer to the description of the application of Uffelmann's test for lactic acid, and in view of the great importance of this test as an aid in diagnosis Dr. Shufflebotham will pardon me for drawing attention to the passage. The test is thus described. Uffelmann's reagent "consists of 10 cubic centimetres of a 5 per cent. carbolic acid solution and 20 cubic centimetres of distilled water. To this is added one or two drops of solution of perchloride of iron and an amethyst blue colouration is obtained. The solution should be prepared fresh each time as it does not keep. In the presence of lactic acid the blue colouration is changed to yellow. ..... Hydrochloric acid has no effect on this reagent." This last statement is the point to which I take exception and which if not corrected may be the means of vitiating the results obtained by the application of the test. The purple blue colouration produced by the action of ferric chloride on phenol is familiar to every chemist, and it is equally well known that the colouration is only produced in neutral or slightly alkaline solutions. It is not developed if there is the slightest excess of acid, and when developed in a neutral solution it is entirely discharged by the addition of acid. So far, therefore, from hydrochloric acid having "no effect" the very reverse is the case, as the reagent is useless in the presence of free hydrochloric acid. It may be replied that the reference is restricted to the use of the reagent in testing gastric contents in which the percentage of free hydrochloric acid is usually very small, and while it is quite within the bounds of possibility that the proportion of free acid may be so minute as not appreciably to effect the result it is not safe to trust to this being the case without careful experimental evidence. Taking the percentages of lactic acid and hydrochloric acid found in a number of the cases quoted by Dr. Shufflebotham—namely, 0·05 per cent. and 0·02 per cent. respectively—I find that while a solution containing the former strength, 0·05 per cent. lactic acid, gives with the reagent a brilliant yellow colouration, the colour is scarcely perceptible in a solution containing 0·05 per cent. lactic acid and 0·2 per cent. hydrochloric acid, and quite imperceptible if the proportion of hydrochloric acid be very slightly increased or that of the lactic acid decreased. From these facts it is obvious that the test cannot be relied on when applied simply by adding the reagent to the gastric contents filtrate unless it has been previously ascertained by the phloroglucin test that free hydrochloric acid is entirely absent, a condition which rarely, if ever, occurs. The proper course to follow is to separate the organic acid by Berthelot's ether process, as described by Dr. Shufflebotham, and then to apply the test.

In place of Uffelmann's reagent I recommend one that is quite as satisfactory and much more convenient for use. It is prepared by dissolving four grains of sulphocarbolate of zinc and two grains of ferric chloride in half an ounce of distilled water. The colour is not blue, as with carbolic acid, but dark ruby, and the reaction is exceedingly delicate, so much so that 1 part of lactic acid in 100,000 can quite readily be detected by using a full six-inch test-tube and looking down through it on a white surface. The advantage of this reagent is the convenience with which it can be prepared and the certainty that it will never vary in depth of colour. I would suggest that medical men would find it particularly handy to have the reagent in tablet form. Using perfectly dry ferric chloride the two salts can quite well be mixed and if preserved from moisture there is no reason why a compound tablet so prepared should not keep indefinitely. I am, Sirs, yours faithfully,

Glasgow, Sept. 24th, 1900. THOMAS MABEN, F.C.S.

## "THE TREATMENT OF ACUTE ALCOHOLISM BY LARGE DOSES OF DIGITALIS."

*To the Editors of* THE LANCET.

SIRS,—With reference to the above I would like to point out that in Nelligan's Materia Medica and Therapeutics, edited by Macnamara, 1868 (Dublin), will be found, under the heading of Digitalis, that Jones of Jersey gave large doses of the tincture to his patients who were suffering from delirium tremens with very beneficial results. I believe the first heroic doses were given quite in error through the dispenser mistaking half-drachm for half-ounce doses, so it will be seen that the treatment is by no means of recent origin. I am, Sirs, yours faithfully,

EDWARD C. CLANCHY.

Battersea-park-road, S.W., Sept. 24th, 1900.

## "THE PREVENTION OF DISEASE IN THE FIELD."

*To the Editors of* THE LANCET.

SIRS,—May I briefly reply to some difficulties you have suggested to my proposition that on active service all water used for drinking purposes should be boiled or filtered?

1. You "would urge Dr. Canney to put forward his proposals for the consideration of those more immediately concerned with the question which he has taken up." I cannot help thinking that those most "immediately concerned" are not the War Office but the whole public who are watching their relatives through this anxious struggle. If the public make it a *sine quâ non* that no general can come back with credit from a campaign with a heavy list of casualties from preventable diseases all "difficulties" in the way of prevention will rapidly fade away. Men do not mind facing fair war, but for thousands to have to go through (and too often, alas, not get through) typhoid fever and dysentery—both preventable filth diseases—with scant attention and nursing and often terrible feeding is too cruel to be tolerated. Seeing that men have had to drink infected water almost everywhere in South Africa it would appear that if there are any others more "immediately concerned" in protecting the army from destruction they must have encountered obstacles and difficulties at the hands of other War Office departments, such as you probably refer to as the "practical difficulties in the way of it being carried out."

2. Flies and dust as carriers of typhoid bacilli. I think very few bacteriologists would uphold the latter agency. Both agencies would require to find the bacilli first before they could carry them. My proposition was to keep the army free from typhoid fever (and largely from dysentery) from the first day of landing. There would then be no dejecta from which the bacilli could be obtained (any suspicious case being treated as typhoid fever, as regards dejecta, antiseptically). Seeing that every man probably in South Africa has been exposed to infected water or utensils it seems unnecessary to assume "dust and flies" without absolute proof. This theory would militate against any proposed plan for abolishing typhoid fever and dysentery as mainly water-borne diseases.

3. "*It has not been the experience of medical officers in India and elsewhere that immunity from disease can be guaranteed by the use of boiled water or of filters.*" This would be a most serious objection if the medical officers had shown at the same time that no other water had been used in the bazaars or elsewhere outside the barracks, that all milk had been boiled, that utensils had not been washed in infected water, and that the toilet water and water used for salads, &c., had been boiled. If any of these things had been left undone no weight would be attached in this country by any bacteriologist to the Indian medical officer's statement.

4. Thirst. The extra half hour (with present machines) is doubtless a difficulty. The occasions would be very rare with a smart "water corps," as smart as the Royal Artillery, that the men would not with education wait the time. Further, a smart "water corps" could perhaps obviate a man arriving in the desperately thirsty condition. Wilful disobedience could be met in other ways.

5. Transport. I have shown that 500 mules would have carried the boiling machines (one per 100 men) and fuel (petroleum) for 10 days, sufficient to boil four pints per man per day for the whole of Lord Roberts's army of 50,000 men moving from the Modder to Bloemfontein. If the mules had been killed *en route* the position would not have been worse than without the attempt; if, on the other hand, the "water corps" had got them along safely there would have been practically no suffering, from 15,000 to 20,000 less to treat at Bloemfontein and Kronstad for weary months under heartrending difficulties. In this scheme I have suggested as transport pack mules, thus disposing of "single lines of railways," roads, and other "difficulties." From the outset the transport of a "water corps" would be sacred. No general could touch it for any purpose whatsoever. It is obvious that no general or transport officer will accept the additional transports with pleasure, but if there is no better scheme in the field there must be no escape.

6. With regard to the difficulty of knowing when the water may be contaminated I have assumed that all water in war is contaminated as the only safe hypothesis.

I am, Sirs, yours faithfully,

Sept. 24th. LEIGH CANNEY.

## RHEUMATISM AND TONSILLITIS.

*To the Editors of* THE LANCET.

SIRS,—I trust you will permit, and that Dr. Poynton and Dr. Paine will pardon, my claim—quoting the opinion of another—to be "the first to emphasise the etiological, semeiological, and therapeutic analogy between tonsillar inflammations and the arthritic diathesis." My views on the close relations of rheumatism and tonsillitis are recorded in the first edition of my work "The Throat and its Diseases," published in May, 1878, and treatment of tonsillitis by salicylate of soda—then a new remedy—was first recommended. At the meeting of the British Medical Association at Leeds in 1889 Dr. Archibald Garrod, while conceding me British priority amongst the "moderns," mentioned Stoll (1777) as the first writer to speak of rheumatic angina, but on that occasion I was able to cite still earlier authors—viz.: Sauvage (1771), Balls (1762), and Musgrave (1710). I also on the same occasion quoted from a letter I had received from Sir Andrew Clark in which he said: "If one will think merely of the rapidity with which the tonsil manufactures and discharges lymph cells it will not be difficult to see how a sudden suppression of this process, the accumulation of effete matters in the crypts, and the filling of the lymph spaces with products of bacteria life, and with matters undergoing evolution, may contaminate the blood and originate the troubles considered as rheumatic." I was at once ready to accept this interpretation which at that time represented a decidedly advanced view. Since that date this contamination of the system, or blood-poisoning, has been acknowledged to be of microbic origin by several observers. In the fifth edition of my book the subject of tonsillitis has been treated from the bacteriological point of view, and I have tabulated the micro-organisms found in 100 cases of tonsillitis by our hospital bacteriologist, Mr. St. George Reid.

Without going into detail it may be stated that various forms of staphylococcus, either alone or associated with other organisms, were found in 62 cases, streptococcus in 58 cases, and diplococcus in 32 cases. With respect to this last named organism I have pointed out in my monograph on "Diphtheria and its Associates" (p. 48) that diphtherial "throats in which diplococci are predominant are 'dirty' in character and the pseudo-membrane slow to clear away."

In the article under consideration it is mentioned that a diplococcus found in acute rheumatism has a disposition to grow in culture as a streptococcus, and in most of the photo-micrographic illustrations of diplococci in my book the organism is associated with streptococci. In one case (No. 22, p. 131) which presented certain aspects of diphtheria, but which was really one of acute lacunar tonsillitis, the diplococcus was found in almost pure culture. Of course, I make no claim to originality in these observations, and, indeed, I have endeavoured to give full credit to other workers, continental, British, and transatlantic, in the same field. I only now draw attention to them as in some sense confirmatory of the much more elaborate and complete investigations of Dr. Poynton and Dr. Paine.

I am, Sirs, yours faithfully,

Mansfield-street, W., Sept. 24th, 1900. LENNOX BROWNE.

## "POISONING BY CARBON MONOXIDE."

*To the Editors of* THE LANCET.

SIRS,—Some years ago I used to see an "ironer" who was the subject of attacks of vertigo, headache, and visual hallucinations when she awoke in the morning, but no amnesia or sickness. She was always worse after "glossing" and during drying. She stated that many other women in the trade suffered from headache, &c., but that they usually attributed it to the "heat." May I add one or two other references to those given by Dr. Elgood in his very interesting paper in THE LANCET of Sept. 15th (p. 805)? Ruata[1] recorded a case of active delirium lasting for five days after exposure to the fumes of a coke stove in a close room. Voss[2] reported an instance of poisoning of five in a family with two fatal results. One of the fatal cases had well-marked convulsions and tetany-form spasms. Régis[3] points out that in the acute forms of poisoning a very prominent symptom is retrograde amnesia. He has also observed rapid and incurable dementia follow in prolonged chronic or professional toxæmia in ironers, whose previous symptoms included vertigo, mental obtusion, hallucinations, and even delirious conceptions.

I am, Sirs, yours faithfully,

Sept. 24th. J. CHRISTIAN SIMPSON, M.D. Edin.

## "LODGE PRACTICE IN BRITISH COLUMBIA."

*To the Editors of* THE LANCET.

SIRS,—Your Canada correspondent in THE LANCET of Sept. 22nd (p. 911) falls into an error when he says that "not a single medical man throughout the Dominion of Canada made any response whatever to this appeal." No one is allowed to practise in British Columbia whatever qualifications he may possess until he passes an examination in anatomy, chemistry, physiology, pathology, materia medica, medical jurisprudence, theory and practice of medicine, surgery, clinical medicine, clinical surgery, obstetrics and diseases of women and children, in addition to paying $100. The same applies to Ontario and Manitoba. With a British qualification one can practise in the North-west Territories on payment of $50. Hoping this may be of service to anyone going out to settle in Canada,

I remain, Sirs, yours faithfully,

PIERS J. HATTON, M.B., C.M. Edin., &c.

Manchester-street, W., Sept. 24th, 1900.

## THE GENERAL ELECTION AND THE MEDICAL ACTS.

*To the Editors of* THE LANCET.

SIRS,—The Accrington and District Medical Society have taken the opportunity given by the General Election to send a deputation to both the candidates before the constituency asking them to pledge themselves to support any amendment of the Medical Acts which may be brought forward by the General Medical Council or the British Medical Association, especially with a view to registration being the sole right to practise medicine, surgery, or any of their branches. The society further suggests that the medical societies in every electoral district should immediately take similar steps.

I am, Sirs, yours faithfully,

ELWIN H. T. NASH, M.R.C.S. Eng., L.R.C.P. Lond.,

Accrington, Sept. 26th, 1900. Honorary Secretary.

*** A telegram received as we go to press states: "Both candidates absolutely agree with proposals of deputation."—ED. L.

[1] Gazzetta Medica di Torino, No. 24, 1892.
[2] Deutsche Medicinische Wochenschrift, Oct. 6th, 1892.
[3] Practical Manual of Mental Medicine.

## THE FIELD SERVICE MANUAL, ROYAL ARMY MEDICAL CORPS.

*To the Editors of* THE LANCET.

SIRS,—There is the greatest possible need of a really good "Field Service Manual" for the Royal Army Medical Corps. The present little pamphlet is a thoroughly bad book and of no use for its purpose. The French army have a field service book of regulations of considerable size, well illustrated, and a complete help to all concerned; our booklet is valueless and unworthy of the army. The Indian Army Field Service Manual is a practical and useful book. I wish ours was even one quarter as good. Unfortunately it is not. I am, Sirs, yours faithfully,

Sept. 24th. RE-MODEL A USELESS BOOK.

## NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

*The Increase of the Plague Epidemic but the Decline of Famine and Cholera.—The Anti-typhoid Inoculations in India Last Year; Favourable Results.—A New Theory for Beri-beri.*

THE deaths from plague throughout India are still mounting up. For last week the number was 691—an increase of 62 on the previous seven days. In the middle of July it was only 198, so the development has been somewhat rapid. The recent increase is chiefly in the Mysore State and in the Bombay districts. Mysore city shows a sharp attack and Poona once again shows a serious increase of the disease. During the past month 141 deaths have occurred in the latter city—the increase being especially marked during the past fortnight. It will be remembered that it was at this season that the terrible outbreak occurred last year. The authorities have issued a notice for certain of the inhabitants to vacate their houses within four days and stay in the health camp. Dead rats have been found lately in many places. The new regulations are being tried. Affected places are disinfected, but segregation has been done away with and there is no compulsory inspection. In Bombay and Calcutta the amount of plague continues about the same, Calcutta reporting 85 deaths and Bombay city 49. The figures for Calcutta include "suspected" deaths. The general mortality in Bombay city is decreasing and for last week 1224 deaths were reported. As, however, the cholera and plague returns only account for 234 deaths and the average mortality is under 600 there is still a balance of about 400 deaths unexplained. The death-rate is over 77 per 1000 per annum. Famine and cholera are fortunately on the decrease. The last famine figures show less than 5,000,000 under relief, but there are still no less than 3,054,000 under gratuitous relief. Cholera is decreasing nearly everywhere.

With reference to the anti-typhoid inoculations in India last year the *Indian Medical Gazette* publishes some important figures. There were 1312 cases of typhoid fever amongst the British troops with 348 deaths, a death-rate of over 25 per cent. The ratio of admissions to total strength was 20·6 per 1000. There were 4502 inoculations, and amongst these men there were only nine deaths from typhoid fever. This gives 0·2 per cent. of strength. There were 44 admissions, giving 0·98 per cent. of strength. Amongst the non-inoculated in the same corps and at the same stations, of 25,851 men there were 657 cases and 146 deaths, giving the relative percentages of admissions and deaths as 2·54 and 0·56. This is strongly in favour of inoculation. I do not quite understand, however, why the admission-rate among the non-inoculated should be 2·54 per cent., whereas the ratio of total admissions to total strength of British troops was only 2·06 per cent. It is at least satisfactory to see so great a benefit, more especially when it is concurrent with a fall in the admission-rate for enteric fever in 1899 from 36 in 1898 to 20 per 1000 in 1899. The above figures are for the whole year and include a much larger number of men inoculated than were referred to in Professor Wright's recent article.

A theory has recently been put forward that beri-beri is due to the consumption of mouldy rice. This, of course, is not the first time that the disease has been connected with some kind of food. Its rapid disappearance from the Japanese Navy may have been due to better dietary, but, on the other hand, mere absence of nitrogenous food does not produce any condition approaching this disease. The chief argument against the mouldy rice theory is that the disease is known to have broken out amongst communities in which the food was generous and varied and in which rice formed but a very small proportion of the diet. Moreover, fungoid growths do not withstand the heat necessary for cooking rice.

Sept. 6th.

## THE TENTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

(FROM OUR SPECIAL CORRESPONDENT.)

### THE WORK OF THE SECTIONS—(*Conclusion*).

#### THE BACTERIAL TREATMENT OF SEWAGE.

ON the last morning of the Congress, Friday, August 17th, the interest in the Third Section, which was beginning to flag, was vigorously revived by Mr. S. H. ADAMS of York. He gave a brief summary of his report on the bacterial treatment of sewage, but he had provided himself with a lantern and showed photographs on the screen of the various types of bacteria beds employed in England. Dealing first with the experiments made by Mr. Dibdin upon the one-acre filter at Barking, he explained that it lost its capacity and was gradually choked up when worked continuously. On the other hand, when worked intermittently it retained its purifying capacities. He then instanced the Sutton beds as an example of double treatment and the Hampton beds as an example of triple treatment. The automatic apparatus designed by himself for working such filtering-beds was shown with views of the sludge in movement and when quiescent. Views somewhat more pleasing in appearance of the Exeter works were also thrown upon the screen. As an example of the continuous system on a large scale mention was made of the filters installed at Salford by Mr. Corbett. The sewage is here discharged from suitably-arranged pipes in a fine spray over the entire surface. The use of coupled syphons for flooding a filtering area was explained, as was also the operation of Colonel Ducat's interesting aërating filters at Hendon. Finally, and in support of the statement that the removal of sludge by biological means was not the least important feature of the system, some English sludge lagoons were shown. Paragraphs quoted from Dr. Rideal's work were read in support of the conclusion drawn by the speaker to the effect that biological processes aid by destroying, and not by increasing, the vitality of dangerous organisms present in sewage.

The section expressed its thanks to Mr. Adams for the trouble which he had taken in bringing forward all this important information, but no discussion ensued.

#### THE ORIENTATION OF HOSPITAL PAVILIONS.

The section now relapsed into the question of the sun's rays.

Professor SORJANI read a paper on the Orientation of the Pavilions of Hospitals so that they should receive the maximum of direct rays from the sun. Dealing with the mean European climate, Professor Sorjani drew the plan of the pavilion, which he enclosed in a circle. He then divided the circle into 24 hours. Outside the circle he drew a line from 9 o'clock to 15 o'clock. This represented the minimum amount of sunshine, the rays from this line alone reaching the building. Then he drew another line from 6 o'clock to 18 o'clock, which represented the mean sunshine, and from 4 o'clock to 20 o'clock, which gave the maximum amount of sunshine possible. As 24 o'clock was the north and 12 o'clock the south the plan inside this circle showed what portions of the building would receive the direct rays from the sun, and he concluded that it would be best to build from east to west.

Dr. PUTZEYS, delegate of the Belgian Government, pointed out that in many European countries the question of the prevailing wind and rain was as important as that of the rays of the sun. In western Europe, most of the rain and wind came from the south-west; therefore the small side or end of the pavilions should be to the south-west and the north-east. The longer walls would thus escape being continually soaked by the rain and it was worth sacrificing

some sunshine for the sake of dryness; otherwise it would be necessary to have double walls.

M. EMILE TRÉLAT urged that though people sometimes objected to the sun darting its rays into the interior of their rooms too much sunshine could not be obtained. This raised a practical question, for it was of no use to strive to build rooms and elevate windows so that the sun might reach the farthermost wall if directly the sun shone the blind was pulled down. Yet, if this were not done what would become of the colour of the carpets, the furniture, the wall-paper, and all decorations generally? The purification of rooms throughout the summer by the admission of the direct rays of sunlight would entail a complete revolution in the decoration and furnishing of our homes. This was a practical domestic difficulty which the hygienists in their eagerness for pure sunlight entirely overlooked.

### THE WAR AGAINST TUBERCULOSIS.

From the Third Section I went to the Seventh Section, where I found that Professor CORFIELD had been speaking on the Reduction of Phthisis in England and Wales. Tables to this effect, which he had exhibited, were still suspended to the wall of the amphitheatre. These showed that whereas the annual deaths from phthisis amounted to the average of 2475 from 1861 to 1871 they were only 1464 from 1891 to 1895 and 1321 from 1896 to 1898. Dr. E. MALVEZ, director of the Bacteriological Institute at Liège in Belgium had read a report on the prophylaxis of tuberculosis. The frequency of this disease among the poorer and labouring classes made it as much a social and economical as a medical problem. When all sections of society possessed the means to live in comfort under good sanitary conditions there would be little or no tuberculosis. Combating the disease in its earliest stages with good hygiene and plenty of food the wealthy succeeded in checking it, but the poorer classes were even refused admission to most of the hospitals. With the establishment in Germany of compulsory insurance the great cost of sick allowances to phthisical patients suggested the necessity of doing something to check this disease. Thus there were now sanatoria where patients were sent at the earliest stage of the malady. Here they were not only treated but taught, so that when they returned home they might know what laws of hygiene they should observe. But in Switzerland and Belgium, where compulsory insurance did not exist, sanatoria had also been erected. Six such institutions existed in Switzerland and a large sanatorium would soon be ready to receive all who suffered from tuberculosis in the province of Liège. Dr. Malvez concluded with the observation that all cases should be reported at the earliest stages, that all forms of poor relief and of medical aid should combine to discover cases and bring them under treatment, and that for this purpose bacteriological laboratories should be established in all directions.

### PILGRIMS AND THE PLAGUE.

From tuberculosis the section passed to yellow fever and to plague. On this latter subject Dr. SANTOLIGUIDO and Dr. STEKOULIS, of Constantinople, with others, agreed that another official international conference should be convoked to deal with the question of the plague. The conference which met at Venice was held before the plague had appeared in the Red Sea, Egypt, Smyrna, Beyrouth, and Oporto. Though these were not serious epidemics, they supplied some practical information of a nature calculated to modify the conclusions of the Venice Conference. Besides, Dr. Stekoulis urged, this conference left several questions open and nothing was decided as to the disinfection of merchandise. With regard to the pilgrims proceeding to Mecca, Dr. Stekoulis explained that the Turkish Government had applied the rules as to measurements on board the pilgrims' ships recommended at the Venice Conference, and since then there had been no cases of overcrowding reported such as used formerly to prevail. Nevertheless, these rules were not enforced by any penal enactment, and therefore another conference was necessary so that failure to observe the rules might be rendered a penal offence. Then there had been the question of the quarantine station of Camaran, which at first was in anything but a satisfactory condition. Consequently at the Seventh International Congress of Hygiene held in London in 1891 Dr. Stekoulis brought forward a resolution condemning the insanitary condition of the island of Camaran. This was communicated some time afterwards to Lord Salisbury and Lord Salisbury suggested to the British Ambassador at Constantinople that he should request the International Council of Health to devote the necessary funds for the building of a proper quarantine station at Camaran. The request thus made by the British Government was accepted by the representatives of the other governments, and with the sanction of the Ottoman Government and under the auspices of His Majesty the Sultan the lazaret has been completely rebuilt. Dr. Stekoulis submitted the plan to the section showing the various buildings erected according to the designs of the French engineer, M. Roullet. Distilled water was provided for the use of the pilgrims and ice was manufactured. The dormitories were well ventilated and drained, and since these works were completed dysentery, which was formerly endemic, had disappeared. Dr. Stekoulis thought that this happy result was one of the clearest cases tending to prove the practical utility of holding international congresses of hygiene. In regard to the suggestion that had been made to forbid the pilgrimages when there was danger of plague, though the French and Russian Governments might favour such a proposal the Governments of Great Britain, Holland, and Turkey could not do so on account of the great number of their subjects who were Mahomedans. The section agreed with this view. Finally, Dr. Stekoulis related that the anti-plague serum had been used at Smyrna. 17 people were inoculated, but treatment was only carried out methodically with three patients. The result was a fall in the temperature, a decrease in the nervous symptoms, and though their lives seemed in considerable danger all three patients recovered. All the members of the hospital staff were likewise inoculated and no one contracted the disease.

The section unanimously carried a resolution requesting the French Government to take the initiative in convoking another International Conference on Plague.

Dr. NOTAL of Japan, who spoke in German, described six cases of plague occurring in Japan which were traced to three persons who had bought goods and had had dealings with one and the same ship.

Dr. PUTZEYS of Belgium said that there should be sanitary police to carry out the stipulations of the international conventions. But when the police, the consuls, the merchants, and commercial men knew nothing about these conventions what could be expected? The Belgian Government in the face of this difficulty had caused a curriculum to be drawn up for the education on these points of the police, the consuls, and the merchants.

### THE COMPULSORY NOTIFICATION OF SYPHILIS.

The Seventh Section then discussed the report of Dr. H. BOURGES, chief of the Hygiene Laboratory at the Paris faculty, on the various measures taken to prevent the spread of syphilis. The obligation to notify such cases was not usually imposed. The Norwegian law of 1860 stated that medical practitioners must report the number of cases they treat, without, however, giving either names or addresses, so that the information would be useful only for statistical purposes. It was in Denmark that the principle of notification was really applied. Here not only had the medical practitioner to notify all cases of syphilis, but the patients could be forcibly detained in hospitals and submitted to subsequent surveillance. The result was that the average prevalence of syphilis in the Danish army during the years 1889 to 1893 was 2·66 per 1000, whereas in all the other continental armies it exceeded 5 per 1000. In Norway the medical practitioner had to give the name and address of the person who had contaminated his patient to the authorities, but it was very rare that the address was known. French soldiers were also told to denounce the women, but according to Dr. Carry and Dr. Jeard of Lyons the results were not very important. Out of 10 women denounced in a licensed house only one was diseased and only one out of 32 inscribed women who lived in private houses, but out of 100 clandestine prostitutes who were denounced 30 were suffering from syphilis.

### THE MEDICAL EXAMINATION OF WOMEN.

In Finland, and even in Norway, when a denunciation had been made the compulsory examination of men was sanctioned. As a rule it was only practised in large agglomerations—barracks, mills, factories, &c. But the Danish law said: "When a case of venereal disease is of such a nature as to justify the fear that it may reappear with contagious characteristics, the doctor who has attended the patient may order him to present himself at a certain ulterior date or to bring a certificate from some other doctor stating that the symptoms of the malady

have not reappeared." Certain countries had preserved old rules that should be abrogated. Thus in Germany the law authorised the immediate discharge, and without compensation, of servants, workmen, and others who were suffering from venereal disease. The factory laws of Russia authorised the employer to break his contract with any workman suffering from this disease. Of course, this was most disastrous in its effects, for in practice it meant that the presence of the disease would be concealed, and therefore it was much more likely to be propagated. Some towns in the United States and cantons of Switzerland had sought to avoid the whole difficulty by abolishing prostitution altogether. About 50 years ago this system was adopted at Munich, but it was not a success, for the prevalence of syphilis among men was tripled in the course of a few years. Therefore prostitutes were allowed to return to Munich, and now most States had abandoned all idea of suppression and resorted to measures of regulation and control. As a rule, however, the details were left to the local police and were not defined by any State laws. The consequence was that there was a total lack of uniformity with very varying results. In Paris, for instance, the women in licensed houses were examined every week and those who lived in private houses only once a fortnight. It was difficult to understand why this difference should be made. On the other hand, at Copenhagen the women were examined twice a week under penalty, if they neglected to present themselves, of four days' imprisonment and of 24 days' hard labour if, having failed to present themselves for examination, it was found that they had contracted a venereal disease. At Lyons women who had been treated and cured were examined twice a week for fear relapses should occur, and in Roumania the names of women who had been diseased were entered on a special register and the women themselves were kept under very close observation. In some parts of Germany, at Frankfort, and at Posen in the Duchy of Anhalt, women who were not prostitutes were examined, such as waitresses in hotels, beer-gardens, &c. Thus there were the extremes from no examination at all to the examination of domestic servants and others, though some of them led quite virtuous lives. According to the statute laws the segregation of women who were diseased was only justifiable in Denmark, Norway, and Roumania, but it was practised wherever prostitution was controlled. In Russia, however, there were not hospitals enough to contain all the women who were diseased. As a rule the treatment was gratuitous.

### THE PROPHYLAXIS OF SYPHILIS.

The most interesting part of Dr. Bourges's report was that which dealt with the prophylactic measures which should be taken. In this both the report and the general tone of the discussion which followed constituted a genuine and important manifestation in favour of the preservation of public health as the first duty. It was not a question of moralisation, but of sanitation, and therefore everything which in the name of religion or of morals tended to prevent immediate and effective treatment was denounced as opposed to the best interests of the whole community. All attempts to impose a stigma led to concealment and to more frequent contagion, therefore this was condemned. Though from the therapeutic and scientific point of view it was an advantage to unite all venereal cases in one single special hospital, from the social point of view this kept patients away and therefore gave bad results. Again, certain German hospitals were denounced because in those hospitals patients suffering from venereal disease were treated differently from the other patients, in not being allowed to receive their friends or to take exercise in the gardens. Benefit societies, sick funds, and all other organisations to provide medical aid which refused to give such aid when the patient suffered from venereal disease, or those hospitals which charged for the treatment of this disease and not for other diseases were strongly condemned. Whatever might be thought of the patient the defence of the community rendered it necessary that such patients should obtain prompt gratuitous treatment without any stigma being attached thereto. This was the only way of preventing concealment and of checking the spread of the disease. This was more particularly necessary in countries where prostitution was free from all sanitary control. Yet Dr. Drysdale had declared that throughout England there were not as many beds available for the treatment of venereal disease as in the single town of Paris. Undoubtedly syphilis was in the main propagated by prostitutes and therefore the most effective prophylactic measure was the frequent medical examination of these women. But there were also other means of propagation which, with the exception of the spread of the disease by wet nurses, had been entirely neglected. Glass-blowers and other workers who passed from mouth to mouth the same instrument, hair dressers, cooks, and other manipulators of food, were all capable of spreading syphilis to perfectly innocent persons. Moralising was of service in so far as it succeeded in persuading women to leave the ranks of prostitution, but where by imposing a moral stigma it prevented the prompt treatment of the disease it worked unspeakable mischief, and from this the innocent suffered as well as the guilty.

In the course of the discussion that followed, Dr. DROUINEAU urged that it was necessary to look upon syphilis simply as an ordinary contagious disease. To do this would imply the taking of special precautions. Why not apply the same antiseptic measures—namely, notification and isolation? Public authorities were under the same obligation to attend to this matter as to attend to the suppression of smallpox. What was justifiable in the one case was justifiable in the other. In the provinces they had abolished venereal wards; they no longer hid such patients in garrets, &c., but they sought to attract them instead of frightening them away.

Dr. LANDOUZY was energetic in his protests that the administration should not seek to moralise. Syphilis was contagious like many other diseases; it had the same etiology and needed the same medicaments and prophylaxy. Powers must be acquired to compel the patients to go to the hospital. The patients might be made to pay according to their means but in any case they must be treated and isolated. In the near future various States would probably spend enormous sums to fight tuberculosis and the same would have to be done against syphilis. The stupid idea as to a mortal sin being the cause must be extirpated.

Dr. BERTHAUD said that all agreed that the terms "secret" and "shameful" diseases must be abolished. The question had its social, economic, and police aspects as well as its medical interest. So long as the criminal instead of the sanitary police were employed a sense of shame would prevail. At the Deontological Congress it was agreed that syphilis should be treated on precisely the same footing as all other diseases. Being contagious it should not be shameful or secret.

Professor VALLIN, who presided over the section, thought that though there should be sanitary police the criminal police were also concerned; they had a right to watch prostitutes as a matter of public order and decency.

Dr. LANDOUZY, speaking again, thought that all encouragements should be given to licensed houses as these were far preferable to hidden places that could not be watched. He could not understand why a woman who spread syphilis as her daily business should be allowed to go free while a butcher who sold diseased meat was prosecuted. The woman and the meat were both offered to the public for sale and both should be inspected. They had police against bad meat, they had international conventions against the plague, but syphilis was at the door of every household and nothing was done to prevent its entering.

Dr. BOURGES, the author of the report, thought that medical education was often insufficient with regard to venereal diseases and that it should comprise a certain time spent in syphilitic wards. An Italian practitioner explained that this had been the custom in Italy for twenty-five years.

The section did not come to any definite decision. The chairman, Professor VALLIN, thought that the motions at the end of the report were too lengthy to be put to the vote. But the discussion was sufficiently emphatic in its general tone. Everything should be done to enable both men and women to seek treatment at the very first symptom. There should be no deterring influences brought to bear. Benefit societies, &c., should not refuse medical attendance and sick allowance, and the State and municipalities should provide ample accommodation for those who could not afford to pay. Prostitutes, as persons carrying on an unwholesome trade, must be examined. As for compulsory isolation this was scarcely practicable except with regard to soldiers and prostitutes.

### CONCLUSION.

This discussion brings me to the end of what I was personally able to see and hear of the Congress, and as there were eight sections much was said elsewhere of equal interest. But a full account of the Congress would fill a volume, and doubtless when the official report appears it will

prove to be a weighty tome. Perhaps, however, what I have been able to describe will suffice to show not only that these congresses are interesting and instructive in themselves, but that they do influence the legislation of many countries and do help to bring about useful reforms. As for the work of the sections which I was not able to attend—for it is not possible to be in eight different places at one and the same time—some idea may be gathered of what they did from the resolutions which they adopted and which were confirmed at the general and final meeting of the Congress. The Congress was not so numerously attended as were the previous congresses; it was therefore more compact, more easy to manage, and everything was carried out punctually according to the programme; there was no hitch, no disappointment, and the members and delegates finally separated satisfied at having accomplished a good work.

# THE CONGRESSES ON PSYCHOLOGY AT PARIS.

(FROM OUR SPECIAL CORRESPONDENT.)

### A MULTITUDE OF PSYCHIC INVESTIGATORS.

THE number of international congresses which have just been held in connexion with the Universal Exhibition at Paris and which dealt with psychic phenomena may be taken as evidence of the increasing interest this subject is awakening. Many of the best-known scientific authorities on these questions have attended either the Second Congress of Hypnotism, or the Fourth Congress of Psychology, or both, and have helped to found the newly-created International Institute of Psychology. Then there has been the International Congress on the History of Religions, which at first sight seems to be quite a different subject. But this Congress discussed the question of the miracles which all religions claim as confirming their faith. Then folk-lore was discussed with its wonderful stories of witchcraft, necromancy, &c., and evidence is being carefully collected to attempt to show that these popular delusions and superstitions might occasionally have had some foundation in the facts now scientifically demonstrated of the power of suggestion on certain hypnotic subjects. Of course, these are points still involved in much obscurity and about which doubts may very justifiably be expressed; nevertheless, it is a sign of the times that they have brought together men of science from all parts of the world who are determined to sift the evidence and by practical experiments to demonstrate what is possible. The result of these discussions and experiments would fill many volumes and I cannot attempt even to summarise what was said and done. Those who are interested must apply to the persons principally concerned, to the responsible general secretaries, and judging by the courtesy by which the French are distinguished there is no doubt but that they will receive printed information, reports, &c. Thus, for the proceedings of the International Congress on Hypnotism applications should be made to Dr. Bérillon, 14, rue Taitbout, Paris, and for those of the Congress on Psychology to Dr. Pierre Janet, 21, rue Barbet-de-Jouy, Paris. M. S. Yourievitch, Attaché of the Russian Embassy in Paris, 19, rue de l'Université, is the general secretary of the International Psychological Institute.

### SUB-CONSCIOUSNESS.

The Congress on Hypnotism was well attended. Dr. JULES VOISIN, of the Salpêtrière Hospital, presided and Professor RAYMOND from the same hospital delivered the inaugural address. Reports were read by Dr. OSKAR VOGT of Berlin and by Dr. PAUL FAREZ on the Value of Hypnotism as a Means of Psychological Investigation. The latter propounded the somewhat startling theory that man was not composed of one but of several individualities. There was a chief among them who governed, but under hypnotism this mental leader might be converted into a mere spectator, conscious or unconscious. Then the secondary individualities who were autonomous, though disciplined in hierarchical order, were able to act on their own responsibility. Thus there was, according to this theory, a psychological atomism just as undoubtedly there was a chemical atomism. These sub-conscious selves were described as veritable psychological laboratories, which received and registered impressions. These impressions, &c., ran a great risk of being entirely forgotten through being over-ridden by the dominant self or the chief in the hierarchy of the many selves that were gathered together in the one individual. By hypnotism we might, as it were, temporarily dethrone the chief and then the subordinates were free to tell what they knew. Thus memories of things long forgotten were recalled and faculties evoked which in the normal state were obliterated or rather kept in the background.—Dr. FÉLIX REGNAULT, in a report on the same subject, sought to show how hypnotic ecstasy explained the ecstasy described in the lives of saints and urged that the part played by suggestion in the action of crowds would furnish a totally different explanation to many of the most important facts of history and had more to do with the winning of battles than the strategy of generals and the weapons of the combatants.—Dr. P. JOIRE of Lille, dealing with the forensic aspect of the question, thought that the power which hypnotism gave might be exercised for evil as well as for good, yet the police records showed that such cases were very rare. On the other hand, the scientific knowledge of hypnotism could render very great service in the discovery of criminals. To hypnotise a person so as to make him confess his crimes would be equivalent to the re-establishment of examination by torture. But the victim of a crime might well be questioned under hypnotism, his memory thus being revived, and the police put on the track of the criminal. Many other questions were raised, but this brief mention of one or two among them may serve to give some idea of the Congress.—The members visited the Salpêtrière Hospital and Dr. Bérillon's clinic in the rue des Arts, where they witnessed the treatment of the patients.

### THE INTERNATIONAL PSYCHOLOGICAL INSTITUTE.

The Fourth International Congress of Psychology was very numerously attended, though both Professor Lombroso and Professor Ferri, from Italy, who had promised papers, were not able to come. The German professors, however, were in great force and read several papers. One of the most interesting features of this Congress was the contest that arose on several occasions between the materialist and spiritualist schools. The latter must not be confused with what in England is improperly called "spiritualism" instead of "spiritism." By "materialist" is meant the school that traces every mental phenomena to some condition of the physical body. The "spiritualist," on the contrary, conceives that the individual may possess some form of intelligent existence that can and does act independently of the animal body. This of course leads to the tremendous problem as to whether mind is the fruit of matter or matter the mere instrument of the mind. Consequently, if we wish to act upon the mind, must we deal with the body or can we act on both mind and body by dealing only with the mind? Then, to answer this fundamental question, have the experiments made in the domain of psychology been of any real service? It was generally felt that the scientific study of material things had progressed out of all proportion to the very slow advance of psychic research, that the whole tendency of western civilisation was to study and develop the knowledge of the material resources of nature rather than its psychic or spiritual powers and knowledge. Consequently when it was proposed to the Congress that an international society should be formed so as to establish an International Psychological Institute the suggestion was warmly supported. This institute has now been established and possesses a very influential committee, comprising, among many others, Mr. James Mark Baldwin, Professor of Psychology at the University of Princeton; Professor W. F. Barrett, F.R.S., of the Royal College of Science, Dublin; Dr. J. Milne Bramwell (London); Sir William Crookes, Professor Oliver J. Lodge, F.R.S. (Liverpool), and other English and American medical men. Nearly all the leading French authorities on this subject are members of the committee, such as Dr. Pierre Janet, Dr. Paul Joire, Dr. Bernheim Baraduc, Dr. E. Boirac, Dr. Bouchard, Dr. Duclaux (director of the Pasteur Institute at Paris), Dr. Durand-de-Gros, Dr. Liebeault of Nancy, Dr. E. Metchnikoff of the Pasteur Institute, Dr. Charles Richet, Dr. Ch. Ribot, and others. From other countries may be mentioned Professor Mendéleieff of St. Petersburg, Dr. Ochorowicz of Warsaw, Dr. F. von Schrenk-Nötzing of Munich, and Professor Flournoy of Geneva, Professor Lombroso of Turin, Dr. P. Visani Scozzi of Florence. Altogether there is here a list of men which gives good promise if instead of merely lending their names

to the institute they will also work in conjunction with one another to elucidate the problems taken in hand.

HUMAN VIBRATIONS.

To return to the Congress of Psychology, what is likely to interest the greatest number, at least of outsiders, are the material facts that can be brought forward. But before it is possible to reach a fact it is most necessary to be able to detect a fraud. In this respect Dr. Encausse, who for many years was a co-worker with Dr. Luys in the hypnotic wards of the Charité Hospital, submitted some drawings of tables, chairs, sofas, &c., which were so arranged with electric wires that they would at once reveal even in the dark any fraudulent movement on the part of a so-called medium. If such contrivances were in more general use much of the prevailing imposture would be rendered impossible. Then Dr. JOHN E. PURDON, from California, read a paper on the "Transfer of Sensori-Motor Impulses proved by the Sphygmograph." Dr. J. E. Purdon argued that Mr. John Beattie of Bristol, England, had demonstrated that "emanations from the living body which may provisionally be termed vital vibrations could and actually did under a variety of forms impress themselves" on photographic plates. Dr. Purdon, however, deemed that such action could be more readily studied upon another similar organism. For this purpose the sphygmograph was employed, and the tracing resulting from a great number of experiments showed, it was claimed, that "a forced vibration due to the dominance of a second person propagated in some unknown manner from his nervous system to that of the other person can be obtained."

Apart from the three congresses just mentioned and which are official congresses there have been other non-official congresses where notably "spiritists" have talked a good deal of nonsense and have made any number of affirmations they were absolutely unable to prove. But amid much of this sort of loose talk there have been read some thoughtful papers written by persons who have had lengthy scientific training, and it is all symptomatic of a great and widespread craving for more light on these mysterious questions. The Paris Universal Exhibition in gathering together people from all parts of the world has supplied the opportunity for rendering manifest this growing tendency, this desire to unravel past superstitions, and to bring all strange and as yet unexplained phenomena to the test of scientific investigation.

Paris, Sept. 23rd.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

*Plague in Foreign Ports.*

IN view of the possibility of the introduction of plague into the port of Liverpool the medical officer of health (Dr. E. W. Hope) has issued a short memorandum drawn up by Dr. Balfour Stewart of University College showing the salient features of the disease. Dr. Hope lays stress upon the fact that cases of pneumonia of uncertain character or patients suffering from bubo without apparent cause may seek medical advice. Having regard to these circumstances he has made arrangements for the isolation in the city hospitals of such cases, and the sputum of any doubtful case of pneumonia will be examined on application to Dr. Balfour Stewart at the Thompson-Yates Laboratories, University College. The names and addresses of all persons coming from infected ports are taken on arrival in the port, and Dr. Hope is prepared to give any information in his possession as to the antecedent movements of any stranger to the town. The "memorandum" points out that plague is generally associated with enlarged lymphatic glands, but not always. In the greater proportion of cases the enlarged glands are those of the groins, both the inguinal and femoral chains of glands being involved; next in frequency come the axillary glands; those in the cervical region are rarely enlarged. It is seldom possible to find a peripheral focus of infection; when it is found it is often a mere pimple. In an early case tenderness on pressure over one or other glandular region is found before the glands enlarge. There are two types of plague—pestis minor and pestis major. In *pestis minor* or *ambulatory plague* enlarged and tender glands are found; the constitutional symptoms are malaise and slight rise of temperature. In some such cases of exceptional mildness advice would probably not be sought. In *pestis major* three forms are found: (*a*) bubonic, (*b*) pneumonic, and (*c*) septicæmic. The *bubonic* (*a*) form in which enlarged lymphatic glands occur is the most common. The buboes may vary in size from that of an almond to that of a small orange. At first a hard and enlarged gland is felt, tender on pressure. Afterwards there is generally more or less œdema of the subcutaneous tissue around the gland, and the skin pits on pressure and appears sodden and of a dull red colour. Later the bubo begins to soften in the centre and a hard ring is felt around the breaking-down mass. The patient has an anxious and dazed expression; he appears dull and stupid, as if under the influence of a drug, and later there may be delirium. The conjunctivæ are injected. The temperature varies from about 101° to 104° F. The *pneumonic* (*b*) form is generally that of broncho-pneumonia. It may follow on the bubonic form or it may be primary, in which case buboes are seldom found. It is rapidly fatal. The *septicæmic* (*c*) form has no peculiar characteristics to show that the blood-poisoning is caused by specific infection. It is also rapidly fatal. The *bubonic* (*a*) form is the only form that would be likely to be diagnosed from the symptoms and signs *per se*. A case of broncho-pneumonia where the constitutional symptoms were severe in proportion to the amount of lung trouble or a case of septicæmia which could not be accounted for would suggest the advisability of questioning the family for any other case of illness. Should plague unfortunately come to this city it would be very important to discover the first case. To this end it would help, if the possibility were borne in mind, however remote, of (1) cases with enlarged glands appearing suddenly and without apparent cause; or (2) cases of pneumonia being due to this disease. The following resolution was carried by the council of the borough of Bootle:—

That this council, as the local authority for the borough under the Infectious Diseases (Notification) Act, 1889, doth hereby order that as a case of emergency the said Act shall apply within the borough to the infectious disease known as "plague"; that the cause of such emergency be declared to be (*inter alia*) the present outbreak of bubonic plague at Glasgow and the highly infectious nature of the disease; that such order shall continue in force for three months from its coming into operation at the expiration of one week from the date of the order being advertised; and that application be made to the Local Government Board for their approval of such order.

Sept. 25th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

*Aberdeen Royal Infirmary.*

THE servants of the municipal corporation have declined to accept a suggestion that each should contribute so much regularly to this hospital and, on the contrary, have resolved to contribute nothing at all, holding that the institution should be put on the rates and managed by a popularly-selected body.

*Aberdeen Royal Asylum.*

The managers of the Aberdeen Royal Lunatic Asylum are to purchase at the price of £7750 the lands of Ashgrove, adjoining the present grounds of Elmhill.

Sept. 25th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

*The late Sir William Stokes.*

IT is a sad coincidence that on the day when the account of the funeral of the late Sir William Stokes appeared in the Dublin papers the death of his accomplished sister, Miss Margaret Stokes, was also announced. She was widely known as the author of many standard works on Irish ecclesiastical architecture. Miss Stokes devoted a lifelong study to the subject and since the death of Dr. Petrie she was recognised as the highest authority on the matter.

*The New Veterinary College for Ireland.*

The site for the new Veterinary College in Dublin—already mentioned in THE LANCET—is causing some adverse criticism of the sanitary authorities who are accused of not being sufficiently alert. Mr. Meldon, D.L., F.R.C.S. Irel., writes that the College, if permanently established in its present position, will not alone be a source of great danger to the

public health, but prove an injury to all the valuable property in its immediate neighbourhood.

*Richmond District Lunatic Asylum.*

An epidemic of typhoid fever now prevails at the Richmond Asylum. The medical superintendent reported on Sept. 20th that there were then 22 cases, 14 being among the patients of the institution and eight among the nurses.

*The Samaritan Hospital, Belfast.*

As a result of the *fête* on behalf of this hospital, which was so well organised by Miss Henderson of Norwood Tower, Belfast, and which took place on July 6th and 7th, a net sum of £325 was raised. Dr. J. St. Clair Boyd, one of the hospital surgeons, in accordance with his generous promise that he would clear off whatever remained on the debt has added £125. The Samaritan Hospital has also received a sum of £1000 from the family of the Belfast millionaire—Mr. James Craig.

*The Proposed Technical Institute in Belfast.*

The city corporation of Belfast has very wisely decided to build a new technical school in Belfast and have selected an admirable site in the centre of the city on a portion of the grounds purchased from the Royal Academical Institution. They have also appointed an efficient architect and they very prudently arranged on Sept. 24th to go a little further and to appoint at once a principal for the institute at a salary of £600 per annum, whose coöperation and experienced practical advice would be of great value in settling the interior arrangements of the building and in organising during the interval of its construction. In this way the new principal would find a place in every way suited to his wants.

*Queen's College, Belfast: the President's Report.*

From the President's report just issued I find that during the Session 1899–1900 there were 353 students at Queen's College, Belfast, but as six attended in more than one faculty there was a net number of 347. In the Faculty of Medicine there were 214 students, an increase of eight over the preceding session. References are made to the loss the College has sustained in the deaths of Dr. Cuming, Dr. Hodges, and Dr. W. N. Watts, all of whom were professors, and a former librarian, the Rev. G. Hill. A full account is given of the success of the students at the various universities. Dr. W. A. Osborne has been appointed assistant professor of physiology at University College, London; Dr. B. Moore has been selected as lecturer on physiology at Charing-cross, London; Mr. F. G. Dennan, M.A., has been appointed assistant to Professor Ramsay in University College, London; and Dr. W. Hanna, sent out by the Government to India to inquire into the nature of the plague, now occupies a high position in the Plague Laboratory at Bombay. All of these old Belfast College students held research scholarships as founded by Her Majesty's Commissioners for the 1851 Exhibition. The various College museums have been well cared for during the year, and owing to the great and most praiseworthy exertions of Dr. H. O'Neill, the Museum of Hygiene and Sanitary Science has made the greatest progress. A mechanical workshop has been opened. While in the medical school the number of departments has been exactly doubled in the last 10 years a new physical and a new biological laboratory as well as the completion of the buildings erected for the department of chemistry are much needed. The present President has already done so much to improve Queen's College during his period of office that I am sure he will manage to get all these wants supplied.

*Commission in the Royal Army Medical Corps.*

Dr. J. W. West, house physician to the Royal Victoria Hospital, Belfast, has been given the commission in the Royal Army Medical Corps which was placed by Government at the disposal of the authorities of Queen's College, Belfast.

*New Medical Local Government Board Inspector.*

Dr. E. C. Bigger of Belfast has been appointed a medical inspector under the Irish Local Government Board. The appointment has not arisen from any vacancy, but it has been decided to add a new inspector for Ulster in addition to the present one—Dr. C. J. Clibborn—the work being very onerous. Dr. Bigger's district will comprise the northern part of Ulster and his headquarters will probably be Londonderry. Dr. Bigger was senior visiting medical officer to the Belfast Union Hospital and superintendent medical officer of health of the rural portion of the union. He in former years held a dispensary medical district in Belfast. He has thus had an admirable training in the work over which he will now act as inspector. Dr. Bigger was an alderman of the Belfast City Council and a prominent member of the Public Health Committee, and at a meeting of that committee on Sept. 20th a resolution was passed congratulating him on his promotion and speaking of his fitness and high qualifications for the inspectorship.

Sept. 25th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

*On Herpes in general and the rôle of Influenzal Herpes in Pneumonia and other Infectious Maladies.*

M. VIDAL of Hyères laid before the Academy of Medicine in July, 1899, some observations as to the frequency of zonal and other forms of herpes in influenza. During the latest epidemic of influenza he has been able to confirm these observations. M. Vidal has established the relation which exists between herpes, of which disease he gave a general definition, and the method of penetration of different organisms into the body. Localised groups of bacilli, according to M. Vidal, give rise to diseases of different organs which are thus laid open to attack by the secondary bacillary products, while the presence of bacilli in the blood-vessels gives rise to a general infection. M. Vidal related some experimental investigations which he considered to bear out his theory and concluded by describing the part played by herpes in influenzal pneumonia.

*The Physiological Action and Therapeutics of Compressed Air.*

At the meeting of the Academy of Sciences held on Sept. 3rd M. Mosso said that an atmosphere containing as much as 50 per cent.[1] of carbon monoxide was not fatal to mice provided that pure oxygen was also supplied at a pressure of two atmospheres. M. Mosso was able to establish the like facts with regard to larger animals such as monkeys, dogs, and rabbits. A mixture containing 6 per cent. of carbon monoxide showed no harmful effects provided that oxygen was present under a pressure of two atmospheres or air at a pressure of 10 atmospheres, whereas 0·5 per cent. of carbon monoxide will bring about death at ordinary pressures. M. Mosso also found that if the animals were brought straight out of the mixture of oxygen and carbon monoxide into the air they died at once, but that if the mixture were gradually purified the blood was regularly washed (*on produit un véritable lavage de leur sang*), and at the end of about half an hour they could without danger be placed in a normal atmosphere. M. Mosso considered this last fact to be particularly interesting from a therapeutical point of view. Take for instance the case of a mining accident where men live in a condition of partial asphyxiation for hours or even days; it is probable that many of these would be saved if immediately after they were brought up they were placed in an atmosphere containing oxygen under pressure.

*The Last Sign of Life.*

Mr. Augustus D. Waller has reported to the Academy of Sciences a distinctive sign which permits the recognition in a few moments whether any organ or tissue, animal or vegetable, is living or dead. The reaction is based upon the following principle. Living matter responds to an electrical excitation by a current in the same direction. This same substance killed by exposure to a high temperature no longer responds to the excitation, or if it does it shows a polarisation current in the opposite direction. This positive reaction proves, according to M. Waller, that the object examined is not lifeless; it is a general and characteristic phenomenon of living matter as such, and one which is found in the nerves, muscles, retina, skin, liver, &c., in animals, and in the leaves, roots, fruits, seeds, &c., in vegetables. It is their last sign of life by means of which it is possible to recognise immediately whether they are still alive and even, up to a certain point, to measure and to express in figures how much vitality they retain.

*Obituary.*

Dr. Alfred Lamoureux of Paris, Municipal Councillor and Member of the General Council of the Seine, died last week. He had for a long time been suffering from heart disease.

Sept. 25th.

[1] If this percentage is correctly quoted the statement is indeed remarkable.—ED. L.

## ROME.

(FROM OUR OWN CORRESPONDENT.)

*The Anti-Malaria Campaign.*

THE strenuous efforts now being put forth in Italy to combat malaria and tuberculosis make it necessary to return frequently to these topics in order to follow the progress of the campaign against them. In regard to malaria the *Accademia dei Lincei* publishes the first report of the experiments undertaken by Professor Grassi and others along the Battipaglia-Reggio line of railway from San Nicola Varco to Albanella, over a distance of some eight miles. The objects aimed at were two: (1) to prove that malaria can be contracted only through the bites of anopheles; and (2) to find means of overcoming the practical difficulties that stand in the way of an efficient prophylaxis. Altogether 104 persons, including 38 children under 10 years of age, were kept under observation, all of them being railway employés with their respective families, living at the two stations and in various houses, 10 in number, along the line. The locality chosen, the Plain of Capaccio, is among the most unhealthy in all Italy. The persons selected for the experiment had all been examined during the non-malarial season—that is to say, before the anopheles had become infected—and those found to be malarious had been treated with quinine. The preventive measures adopted were the protection of the houses from the entrance of mosquitoes by wire gauze over the windows and the wearing by any persons obliged to be on duty outside after sunset or during the night of a simple veil attached round the hat with elastic, and of thick cotton gloves with tight sleeves. All who could went indoors at sunset and did not come out again till after sunrise. It was found very difficult, especially at first, to induce the people to observe these simple precautions in the efficacy of which they had no faith, but, nevertheless, of the 104 individuals experimented upon, excepting three cases of relapses which had escaped the previous treatment by quinine, not one has so far been attacked by malaria. This is very fortunate, for in spite of all precautions some anopheles succeeded in inflicting their bites, and although the proportion of infected insects is small (1 per cent.) one of these latter might easily have found its way into a house and inoculated some of the inmates. The better to supervise the experiment Professor Grassi spent three days a week on his field of operations, sleeping at the station of Albanella with open windows (covered, of course, with the wire gauze), and the same was done, though for shorter periods, by Dr. Martirano and Dr. Blessich who assisted him. While the subjects of the experiment thus enjoyed a complete immunity from malarial fever the other inhabitants of the same locality, who may be regarded as so many control subjects, not having been protected in any way against the anopheles, fared very differently, having, it is stated, been all attacked, even those living under otherwise superior conditions. Other similar experiments have been carried out by Di Mattei in the Val Savoja[1] and by Dr. Fermi and Dr. Tonsini on the Island of Asinara,[2] near Sardinia. The former place is exceedingly malarious and the mosquitoes are numerous; nevertheless, by the aid of wire gauze over the windows of the house and the use of oil of turpentine on the hands and faces of the five inmates who carried out the experiment the mosquitoes were kept away and no case of malaria occurred during a period of four months. Elsewhere in the locality malaria was raging. In Asinara the conditions are peculiarly favourable for testing the practicability of entirely ridding a given area of malaria by destroying the mosquitoes infesting it. Dr. Fermi and Dr. Tonsini by destroying the larvæ with petroleum and the adult mosquitoes by means of pyrethrum, chrysanthemum, valerian, and zanzolina, succeeded in exterminating anopheles in the island and greatly diminishing the number of culex pipiens. At the same time use was made of wire gauze over the windows of the houses to protect the inhabitants from being bitten, with the result that no fresh case of malaria occurred in the island, although in the previous year 40 persons had contracted the disease there. The experiment was carried out last year from June to November and is being continued this season.

[1] Annali d'Igiene Sper., fasc. 2, 1900.
[2] Ibid.

*The "Sanatorio Umberto I."*

The commission charged with the selection of a site for the Milanese Sanatorium have recommended a place in the Valtellina (one of the valleys leading from Italy to the Engadine), named Sortenna, above the village of Sondalo and overlooking the whole of the valley from Tirano to Belladore. It is situated in the midst of woods at an elevation of close upon 4000 feet above the sea and has an excellent aspect to the south-west. The commune of Sondalo has offered to give all the ground required for the purpose gratuitously. The Novara commission appointed for a similar purpose has chosen a site at Gozzana, in the beautiful neighbourhood of the lake of Orta, at an altitude of 1140 feet above sea level. The aspect is full south and it is thoroughly sheltered from the only wind prevailing on the lake—namely, the north. It is instructive to note the considerations which guided the commissions in their choice of a suitable site. These were shortly as follow: (1) a central position for the different parts of the province; (2) vicinity to a railway station; (3) easy access to a town where all necessaries are readily procurable; (4) vicinity of a good carriage road; (5) ample grounds of a nature suitable for building purposes and varied in its character, partly wooded, partly cultivated, and in meadow; (6) moderate cost of the land; (7) a good elevation above the sea; (8) abundance and good quality of water-supply; (9) sunny aspect; (10) situation sheltered from prevailing winds; (11) choice of walks in all directions among numerous pine and other resinous trees without patients requiring to leave the grounds; (12) electric lighting at small cost; (13) absence in the neighbourhood of factories or densely populated spots; and (14) isolation (by a stretch of intervening ground) from adjoining habitations.

Sept. 24th.

# Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—In September the following candidates passed in the subjects indicated:—

*Surgery.*—J. Black, Manchester; J. W. Bowd, St. Bartholomew's Hospital; D. J. Ferris (Sections I. and II.), Manchester; J. Gallagher, Bombay; E. T. Longhurst, St. Mary's Hospital; C. C. Pratt, St. George's Hospital and Bristol; J. M. Ritchie, Durham; and H. V. Swindale (Sections I. and II.), Middlesex Hospital.

*Medicine.*—A. G. H. Anthonisz (Section I.), University College Hospital; M. A. Curry, Bombay; D. Davies, London Hospital; and M. R. Kapadia, Bombay.

*Forensic Medicine.*—A. G. H. Anthonisz, University College Hospital; D. Davies, London Hospital; D. J. Ferris, Manchester; and M. R. Kapadia, Bombay.

*Midwifery.*—J. C. Baggs, St. Thomas's Hospital; W. A. King, Charing Cross and St. George's Hospitals; and V. F. Wall, St. Mary's Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—D. Davies, J. Gallagher, C. C. Pratt, and J. M. Ritchie.

UNIVERSITY OF DURHAM.—At the Third Examination for the degree of Bachelor of Medicine, held at the College of Medicine, Newcastle-upon-Tyne, in September, the following candidates satisfied the examiners:—

*Second-Class Honours.*—Gayton Warwick Smith, Guy's Hospital; Thomas Corrie Rutherfoord, St. Thomas's Hospital; and James Bowden Waters, College of Medicine, Newcastle-upon-Tyne.

*Pass List.*—Edmund Howard Barrett, M.R.C.S., L.R.C.P., St. Mary's Hospital; Arthur John Spiller Brandon, St. Thomas's Hospital; Samuel Thomas Cochrane, College of Medicine, Newcastle-upon-Tyne; Charles Fisher, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; Ida Emilie Fox, London School of Medicine for Women; George Brittan Gill, Hugh Robert Kendal, John Herbert McDowall, Leonard Clark Newton, and Robert Reid Pirrie, College of Medicine, Newcastle-upon-Tyne; Monica Lucien Mary Robertson, London School of Medicine for Women; and Hermann Heinrich Ruffmann, Frederick George Wilson, Norman Bryan Walker, Thomas Wilson, and Robert Younger, College of Medicine, Newcastle-upon-Tyne.

FOREIGN UNIVERSITY INTELLIGENCE.—*Athens:* Dr. Constantin Savas has been appointed to the chair of Hygiene and Bacteriology.—*Berlin:* Dr. A. Buschke has been recognised as *privat-docent* of Dermatology and Syphiligraphy.—*Cagliari:* Dr. G. Pinna has been recognised as *privat-docent* of Medical Pathology.—*Breslau:* Dr. Richard Stern has been promoted to an Extraordinary Professorship of Internal Medicine.—*Copenhagen:* Dr. Oscar Wanscher has been promoted to an Extraordinary Professorship of

Medicine.—*Erlangen:* Dr. Oscar Schulz has been recognised as *privat-docent* on Physiological Chemistry.—*Genoa:* Dr. Giuseppe Ingianni has been recognised as *privat-docent* of Surgical Pathology.—*Gratz.* Dr. Theodor Pfeiffer has been recognised as *privat-docent* of the Pathology and Therapeutics of Internal Diseases.—*Munich:* Dr. O. Messerer, Extraordinary Professor of Forensic Medicine, has been appointed Honorary Professor.—*Naples:* Dr. Prospero Guidone has been recognised as *privat-docent* of Operative Medicine.—*Palermo:* Dr. Gaetano Lodato has been recognised as *privat-docent* of Ophthalmology.—*Parma:* Dr. Marco Pitzorno has been recognised as *privat-docent* of Anatomy.—*Strasburg:* Dr. W. A. Freund, the well-known gynæcologist, is about to retire from the chair of Diseases of Women. The names mentioned in connexion with the chair are those of Professor Fehling of Halle and Professor Frommel of Erlangen.—*Vienna:* The following *privat-docenten* have been promoted to be Extraordinary Professors: Dr. H. Ehrmann, Dr. J. Pal, Dr. E. Redlich, and Dr. A. Elschnig.

THREATENING A MEDICAL MAN.—At the Tredegar Police-court last week a collier was fined £5, or as an alternative one month's imprisonment, for threatening to assault Dr. Joseph Morgan Richey, who had refused to give a certificate enabling compensation to be claimed.

CARTWRIGHT MEDAL FOR ESSAY ON DENTAL SURGERY.—A scheme has been sanctioned by the Charity Commissioners by which £644 left to the Royal College of Surgeons of England in 1884 will be devoted to providing every four years a "Cartwright Medal" for an essay on Dental Surgery. The medal will be accompanied by an honorarium.

PRESENTATION TO A MEDICAL MAN.—At Newton Abbot, Devonshire, on Sept. 21st, Mr. R. Hambly, on behalf of the nursing class of the St. John Ambulance Association, presented Mr. Richard Henry Grimbly, M.R.C.S.Eng., L.S.A., with a silver fountain pen in appreciation of his services as honorary lecturer.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The Secretary of State for War having granted the President of the Royal College of Surgeons in Ireland two nominations for commissions in the Royal Army Medical Corps Mr. Myles has nominated Mr. J. Langdale Jones and Mr. G. Faber Sheehan, licentiates of the College and past pupils of the College school, for the vacancies.

PURE MILK FOR HOSPITAL PATIENTS.—With the view of procuring a perfectly pure supply of milk for the patients in the Infectious Hospital the Paisley Town Council on Sept. 11th formally opened a model byre for the purpose of providing milk free from tuberculous taint. The byre is managed by a local dairyman who purchased the cows. The corporation had them officially examined under a tuberculin test and all cows exhibiting tuberculous taint were slaughtered.

CHARING-CROSS HOSPITAL MEDICAL SCHOOL.—The students of the Charing-cross Hospital Medical School will open their session on Oct. 1st by giving a conversazione to their friends, commencing at 7.30, among the attractions being physiological, chemical and electrical experiments, and demonstrations of x-ray apparatus. Dr. Abercrombie will show some lantern-slides prepared from photographs taken during a recent visit to Egypt. During the evening concerts will be given and a new and original one-act play will be performed for the first time entitled, *An Unconventional Afternoon*, by Charles Willoughby Stanhope.

BRISTOL ROYAL INFIRMARY.—At the half-yearly board of the governors of this institution held on Sept. 25th it was unanimously resolved, on the motion of the Dean of Bristol (chairman), seconded by Dr. Shingleton Smith:—

That Mr. Richardson Cross having resigned the office of honorary ophthalmic surgeon the warmest thanks of the governors be accorded him in recognition of the very valuable services he has rendered to this institution throughout the last 22 years, during which period he has successively held the posts of honorary assistant surgeon, honorary surgeon, and honorary ophthalmic surgeon, and that he be appointed honorary and consulting ophthalmic surgeon.

At a subsequent meeting of the committee of election Dr. Alexander Ogilvy, B.A., M.D., B.S. Dub., F.R.C.S. Irel., was unanimously elected honorary ophthalmic surgeon in the place of Mr. F. Richardson Cross, M.B. Lond., F.R.C.S. Eng., resigned.

HOSPITAL COLLECTIONS AT FALMOUTH.—The receipts of the Hospital Saturday and Sunday recently held at Falmouth amounted to £78.

NEW WORKHOUSE FOR BARTON REGIS.—On Sept. 18th the Dowager-Duchess of Beaufort laid the foundation-stone of the workhouse for the Barton Regis (Bristol) Union. The total estimated cost is £32,852.

COCKLES AND TYPHOID FEVER.—At the meeting of the Honiton District Council the medical officer of health (Dr. F. M. Reynolds) reported two cases of typhoid fever at Sidbury which were caused by eating cockles obtained from Exmouth.

SELF-INDUCTION OF ABORTION.—An inquest was held in Bath on Sept. 20th upon a married woman aged 36 years. It was proved that deceased had taken drugs and used an instrument upon herself for the purpose of procuring a miscarriage. Medical evidence showed that the drugs were harmless but that the deceased had used an instrument. The coroner said the woman had paid the penalty of her own foolish act and evidently nobody else was implicated. The jury returned a verdict of "Death from septic poisoning."

PHARMACY FOR THE LONDON CONJOINT BOARD.—The Birkbeck Institution is holding classes with practical work in chemistry, physics, biology, and practical pharmacy for the first professional examination of the Conjoint Board. The pharmacy class is conducted by Mr. F. A. Upsher Smith, pharmaceutical chemist, member of the Pharmaceutical Society, and until recently demonstrator of pharmacy and materia medica at the Pharmaceutical Society's school. Preparations for the next Conjoint pharmacy examination will commence on Wednesday, Oct. 3rd, at 6 P.M.

HEALTH OF GLAMORGANSHIRE.—The annual report of Dr. W. Williams, the medical officer of health of the county of Glamorgan, which has just been issued, shows that in 1899 the population of the county was estimated at 616,270. The births during the year numbered 19,868 and the deaths 11,383, equal to a birth-rate of 32·2 and a death-rate of 18·4 per 1000. Of every 1000 children born 202 died under one year of age, the highest infantile mortality that Dr. Williams has had to record. The principal zymotic diseases caused 1753 deaths. Phthisis caused 531 deaths. Five cases of small-pox were notified during the year. Dr. Williams states that works of sewerage and sewage-disposal of considerable importance had been carried out during 1899, but he added that the inspection of dairies, cowsheds, and milkshops was carried out in a very lax way in most districts.

THE UNIVERSITY OF LONDON.—The committee concerned with the nomination of members to represent upon the Senate of the University of London the medical graduates of convocation (including amongst others Lord Lister, Sir Samuel Wilks, Sir William Broadbent, Sir John Williams, Sir Richard Douglas Powell, Mrs. Scharlieb, M.D. Lond., Dr. P. H. Pye-Smith, Dr. S. J. Gee, Dr. W. H. Allchin, Mr. H. G. Howse, Dr. H. Montague Murray, Dr. J. R. Bradford, Dr. W. Pasteur, and Dr. E. Lauriston Shaw) desire it to be known that the selection of Dr. J. F. Payne and Dr. T. Barlow as candidates was made essentially on the following grounds:—First, that these gentlemen are pledged to no party and are prepared to consider the many questions that will come before the new senate without prejudice and to support and strengthen the reconstituted university as a whole. Secondly, that Dr. Payne is a member of the existing senate and that Dr. Barlow was a member of the late statutory commission.

MEMORIAL HOSPITAL, BULAWAYO.—The report of the Memorial Hospital, Bulawayo, for the 12 months ending June 30th, 1899, shows that much activity has prevailed during that time, one of the events being the completion of extensive alterations and additions to the hospital buildings. The cost of maintenance of the institution during the 12 months was £9950. The income was £10,874, made up as follows:—Maintenance fees from paying patients, £3786; subscriptions, £2554; and grants from the British South Africa Company, £4534. The daily average cost for maintenance of all patients, European and white, was 9*s.* 11*d.* The hospital has a monthly grant of £300 from the Government—i.e., the British South Africa Company—

on condition of providing for a daily average of 20 white and 20 native free patients. The total number of patients treated during the 12 months was 1238, consisting of 865 white (836 men and 29 women) and 373 black (358 men and 15 women). Among the whites there were 41 deaths, or 4·7 per cent., and among the blacks 62 deaths, or 16·6 per cent. The most frequent disease was malarial fever, of which there were 461 cases, with 14 deaths. There were also 11 cases of blackwater fever, with three deaths; 48 cases of dysentery, with three deaths; 10 cases of typhoid fever, with one death; and two cases of Malta fever, both of which recovered. The resident surgeon (Dr. F. A. Arnold) was re-engaged for a further period of two years.

PLAISTOW AND CANNING TOWN MEDICAL SOCIETY.—A meeting of the above society was held on Sept. 20th, Mr. F. W. P. Holton presiding. After the transaction of the ordinary business Dr. Edmund Hay, in the absence of Mr. Percy Rose, opened a discussion upon Various Forms of Sore-throat, in which Mr. R. Buksh, Dr. Thomas Anderson, Mr. H. A. de B. Nelson, Dr. Reynolds, and Mr. P. Napier Jones took part.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—The autumn meeting of the South-Eastern Division of the above association will be held at Ticehurst House, Sussex, on Wednesday, Oct. 10th. Luncheon will be at 1 P.M. and members will inspect the asylum and grounds during the course of the afternoon. Members are invited to dinner by Dr. A. S. L. Newington, Mr. H. F. H. Newington, and Mr. T. Newington. The hour will be 6.30 P.M., and the place Ticehurst. Morning dress. The station is Wadhurst, on the South-Eastern Railway.

THE LONDON HOSPITAL MEDICAL COLLEGE.—The following are the results of recent scholarships:—Price Science Scholarship, value £120, J. Roberts; Entrance Science Scholarship, value £60, G. Worrall; Entrance Science Scholarship, value £35 (scholarship divided), A. Salmon and W. D. Hartley; Price Scholarship in Anatomy and Physiology (open to students of Oxford and Cambridge only), value £60, H. M. Turnbull (Oxford University); Epsom Scholarship, value £126, E. L. Sandiland.

# Births, Marriages, and Deaths.

## BIRTHS.

ATKINSON.—On Sept. 19th, at Elmhurst, Hampton-hill, Middlesex, the wife of G. L. Atkinson, M.R.C.S., L.R.C.P. Lond., of a son.

CRAWSHAW.—On Sept. 25th, at 15, Cobcar-street, Elsecar, the wife of J. H. Crawshaw, Surgeon, of a son.

DICKIE.—At Moriani, Assam, on August 28th, the wife of I. L. Dickie, M.B., of a daughter.

ODELL.—On the 23rd inst., at York House, Hertford, the wife of Robert Odell, of a son.

WATSON.—On Sept. 16th, at 1, York-road, Hove, Sussex, the wife of Solomon George Watson, M.R.C.S., of a son.

## MARRIAGES.

BAYLISS—SIMONS.—On the 20th inst., at St. James's Church, Boscombe, by the Rev. F. Cecil Bayliss, brother of the bridegroom, assisted by the Rev. Leofric Cutler, Richard Arthur Bayliss, M.R.C.S., L.R.C.P. Lond., youngest son of Richard Bayliss, of Spondon, Derbyshire, to Kate Diana Hester, second daughter of the late Nathaniel Wells Simons, J.P., of Hawkwood, Boscombe.

RAY—TAUBMAN.—On the 19th inst., at Holy Trinity Church, Bolton-le-Sands, Carnforth, by the Rev. H. T. Greaves, M.A. (brother-in-law of the bridegroom), assisted by the Rev. A. R. Tomlinson, M.A., vicar, John Howson Ray, Ch.M. (Vict.), F.R.C.S. (Eng.), fourth son of the late Wm. Ray, of Whalley Range, Manchester, to Edith, only daughter of the late Wm. Hy. Taubman, of Blackburn.

WILLCOCKS—DUNLOP.—On Sept. 25th, at St. Mary Magdalene's, Stoke Bishop, Arthur Durant Willcocks, M.R.C.S., of Taunton, to Martha ("Pattie"), daughter of the late Matthew Dunlop, of St. Michael's-hill, Bristol.

## DEATHS.

BRADSHAW.—On Sept. 23rd, at Avenue-road, Regent's-park, James Dixon Bradshaw, M.A., M.B. Oxon., in his 53rd year.

HAVILAND.—On Sept. 22nd, at Cedar House, Cheniston-gardens, W., Henry James Haviland, M.D., J.P. for Cambs., aged 74.

THOMSON.—On Sept. 25th, at 14, Coates-crescent, Edinburgh, Thomas Cleghorn, eldest son of John Thomson, M.D., F.R.C.P. Ed., in his 13th year.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Short Comments, and Answers to Correspondents.

## "PROFESSIONAL ORGANISATIONS."

OUR readers will have noticed the correspondence which has been taking place in our columns with reference to the subject of "Professional Organisations." The protagonists were Dr. James Ryley and the Yarmouth District Committee of the Incorporated Medical Practitioners' Association, through its secretary, Mr. W. E. Wyllys. The controversy was commenced by Dr. James Ryley in THE LANCET of August 25th, p. 627. Mr. W. E. Wyllys, on behalf of the Incorporated Medical Practitioners' Association, replied to Dr. Ryley in our issue of Sept. 8th, forwarding to us at the same time some correspondence which had passed between the association and Dr. Ryley at various dates between June 16th and August 26th. We stated in a note to Mr. Wyllys's letter that we had read the correspondence, which was, however, incomplete as the association was waiting for a reply from Dr. Ryley, but that reading the letters had left the impression on our minds that Dr. Ryley ought to have no difficulty in remaining a member of the association without any sacrifice of his principles. It may be as well here to record the fact that the subject in each correspondence was whether or no the medical men attached to the institute in Yarmouth founded by the friendly societies should be met in consultation. Cases of emergency were to be seen in consultation without any doubt, a fact which, so far as we understand, Dr. Ryley does not seem to have realised. A further letter from Dr. Ryley appeared in THE LANCET of Sept. 15th to which the association replied through Mr. Wyllys in THE LANCET of Sept. 22nd, and another appears at p. 968 of our issue of to-day. More letters passed between Dr. Ryley and the association at dates varying from Sept. 8th to Sept. 10th, but their tenour may be reduced to the simple statement that Dr. Ryley resigned his membership of the association and that this resignation was formally accepted. We have therefore nothing to add to our former opinion expressed in our note to Mr. Wyllys's letter in THE LANCET of Sept. 8th, p. 769.

## GERMAN TEXT-BOOKS ON ANATOMY.

*To the Editors of* THE LANCET.

SIRS,—Will you kindly name in your next issue a German text-book of anatomy of moderate size which can be relied on; also publisher of same. I am, Sirs, yours faithfully,

Sept. 24th, 1900. COOL SHADE.

*** Any one of the following works would probably meet the requirements of our correspondent:—A. Voll: Kompendium der normalen Anatomie (eight marks); Fr. Reinke: Anatomie des menschen (14 marks); Ed. Richter: Grundriss der normalen menschlichen Anatomie (15 marks); C. von Langer: Lehrbuch der systematischen und topographischen Anatomie (17 marks). The first of these works is rather condensed. Any of them can be obtained in London from Muller of Star Yard, Carey-street, W.C., or from Dulau and Co., Soho-square.—ED. L.

## "WANTED—A HOME FOR AN EPILEPTIC."

*To the Editors of* THE LANCET.

SIRS,—I am writing to say that there is a good home for invalided Roman Catholic clergy in Clifton kept by the Nursing Sisters Clifton-wood Convent, Clifton. I am, Sirs, yours faithfully,

Bristol, Sept. 25th, 1900. LAURA HEATH.

## FOR RIDERS IN HANSOM CABS.

ON the afternoon of Friday, Sept. 21st, two inventions for use in hansom cabs were exhibited on the Thames Embankment by the inventor, Captain Dickson. One was a modification of the ordinary gravel iron, a wheel taking the place of the usual loop. This wheel in case of the horse stumbling makes a half revolution, thus assisting the horse to recover his footing and lessening the liability of the driver to be thrown from the box. The other invention was a safety strap intended to pass in front of the "fare" and so to keep him from being shot out of the cab in case of an accident.

## "WANTED—A DIAGNOSIS."

*To the Editors of* THE LANCET.

SIRS,—In THE LANCET of Sept. 8th there was a letter from "Inquirer" asking for a diagnosis of a case in which the principal symptom was an iridescent colouration of the urine, looking like blood and yet not being due to blood. I have lately had a similar case which I think may interest "Inquirer" and others of your readers. A boy, aged 13 years, was brought to me with no particular complaint except that his urine seemed to contain blood. He was quite well and comfortable in himself. His urine presented a beautiful pinkish colour and was clear and strongly iridescent. Examination failed to detect any abnormal constituent in the urine, though phosphates were deposited on heating. The pigment, whatever it was, was soluble in chloroform. Inquiry failed to elicit any history that could account for the phenomenon and on the following day the urine was free from unusual colour. Three days later the boy returned and told me that he had discovered the cause of the colouration, which had again followed the eating of some of the ordinary "musk" lozenges such as children commonly buy. There is no doubt that this is the cause in my patient's case, and it surprises me very much that I should never have seen or heard of the occurrence before, for pink musk sweets have been familiar to me from my childhood and are largely consumed every day by children, and yet I have never heard of their producing this effect until now. The appearance of the urine was most distinctive and could hardly have escaped observation. Anyone would have thought that it contained blood. The questions as to what the pigment is and how it affects the urine are of much interest, and I have submitted a sample both of the urine and the sweets to Dr. W. D'Este Emery, of the Birmingham University, who is kindly investigating the matter. The result of his researches I hope may be communicated to you in due time.

I am, Sirs, yours faithfully,

Bromsgrove, Sept. 25th, 1900. CAMERON KIDD.

## "IS IT A COMPANY?"

WE have had forwarded to us a four-page handbill of an institution called The Progressive Medical Alliance. Page 1 is embellished with a view of the building where the Alliance is housed, 57 and 59, Oxford-street, W., and gives the addresses where men only and where women only are seen. Pages 2 and 3 we print below:—

*DISEASES OF MEN.*

The P. M. A.

EXPERTS AND SPECIALISTS

Absolutely Cure all Nervous Complaints, Physical Exhaustion, Fits, Skin, and Blood Diseases and Genito-Urinary Troubles.

Remember . . .

that we are a reputable Medical firm, engaged in a noble calling and that experience has taught us to cure many cases which others have pronounced hopeless, and to use many effective remedies of which ordinary practitioners are ignorant.

The Physicians and Specialists on the Staff of the PROGRESSIVE MEDICAL ALLIANCE are graduates of British, Continental, and American Universities, and have attained a high eminence in their Specialities.

*Nervous, Private, Blood, Skin, and Chronic Diseases specially invited.*

ALL CASES STRICTLY CONFIDENTIAL.

*DISEASES OF WOMEN.*

The P. M. A.

Ladies' Department, 7, Soho Street, is now open for the Scientific Treatment and Cure of all FEMALE COMPLAINTS and is under the Supervision of a Lady Physician of the widest experience and highest qualifications. Amongst the numerous examinations she has passed are the Staats-Examen of the University of Berne, the M.D. Turicensis, the Examination of Physician and Licentiate in Medicine of the King and Queen's College of Physicians in Ireland and the Licentiate in Midwifery of the King and Queen's College of Physicians, Dublin. Having held hospital appointments and enjoyed a large practice, her experience has not only been wide, but practical, and ladies will do well to consult her upon all diseases peculiar to their sex.

HOURS 11 TO 2 AND 6 TO 9.

FRAUEN KRANKHEITEN.

Eine Frau Doktor. Praktische Arzt.

Stunden 11 - 2. 6 - 9.

*Sonntags Keine Sprechstunden.*

ON PARLE FRANCAIS. DEUTSCH WIRD GESPROCHEN

We think it would be as well for the General Medical Council to ascertain who are the graduates of British universities on the staff of the Progressive Medical Alliance. The Council might also take notice of the lady who has passed "the M.D. Turicensis" and also the examination of the Physician and Licentiate in Medicine of the King and Queen's College of Physicians in Ireland and the Licentiate in Midwifery of the King and Queen's College of Physicians, Dublin.

## THE CLUB QUESTION IN LANCASTER.

WE are pleased to note that the dispute between the medical men of Lancaster and the medical clubs has ended in a complete victory for the former. They have obtained an advance in fees from 3*s.* 6*d.* per head per annum to 5*s.* The little campaign has been carried out quietly and with little ill-feeling through the medium of the local medical society, which includes all members of the profession in the

town. Those not directly affected supported their colleagues and thus enabled them to achieve a result that they would have otherwise been powerless to attain. It may serve as an inducement to others to try what a little organisation will do.

## "A SUBSTITUTE FOR BRANDY."

OUR remarks upon the temperance workers substitute for brandy seem to have given Mrs. Oliver and Dr. R. Watson a certain amount of pain. Mrs. Oliver argues that granting that her mixture contains 83 per cent. of alcohol as against 50 per cent. in brandy, both by volume, it does not follow that the patient will imbibe that percentage. She says: "It requires to be very copiously diluted with from eight to 16 times its bulk of water, so that if it contains 83 per cent. when made up by a chemist it only contains 5 to 10 per cent. when used." Mrs. Oliver further says that the value of alcohol in her preparation is not as a drug but as a preservative, and that she must employ an alcoholic tincture as a medium until such time as it may be replaced by another. She further says that several of the constituents of the substitute, such as carbonate of ammonia, ginger, oil of nutmeg, are, singularly or collectively, more potent or efficacious as a tonic and stimulant than brandy. We will take the last of Mrs. Oliver's remarks first. It is true that ginger, carbonate of ammonia, and various essential oils are both stimulant and tonic, but the value of brandy, as we pointed out in our issue of Sept. 22nd (p. 856), lies not in the alcohol which it contains, but in the ethers. We think it quite possible that ginger and carbonate of ammonia, administered in hot water, would be quite as valuable a stimulant as alcohol, if not more so. Dr. Watson, in a signed article in the *League Journal* for Sept. 22nd, argues that the virtue of the mixture is utterly independent of alcohol, but it seems to us that both Mrs. Oliver and Dr. Watson miss the point of our argument. The original prescription was given, according to the *League Journal*, to influence people against resorting to an *alcoholic* remedy, and we repeat that the substitute recommended being much more alcoholic than ordinary brandy is in no way a substitute for it. We are quite willing to allow that a draught given out of a medicine bottle is less attractive than out of an ordinary brandy bottle or that obtained from a public-house; but, as they both contain alcohol, for the one to be put down as containing incalculable possibilities for evil and the other to be recommended to every member of "our guild" is inconsistent, to call it nothing else. The following letters show that we are not alone in this view.

*To the Editors of* THE LANCET.

SIRS,—The short-sighted logic and characteristic righteous indignation exhibited at your matter-of-fact and truthful criticism of the utterly ineffectual and even injurious methods of unscientific temperance reformers recall to my mind another amusing experience of the same order. A friend of mine in Central America used long to distress his sober-minded wife with the too frequent imbibition of his favourite "four crown." All of a sudden he developed strongly-marked total abstinence principles, much to the consolation of his wife and friends. He became, and probably is to-day, a rabid total abstainer, lecturing and arguing that alcohol is always a virulent poison! But in all probability only I and the chemist who made up the pick-me-ups know that our worthy friend and staunch teetotaler took daily a dozen or more drinks of a mixture of the tinctures of ginger, capsicums, cardamoms, and the liquor of the acetate of ammonium with the aromatic spirits of ammonia, in which the proportion of alcohol is much the same as in the substitute for brandy Mrs. Oliver's friend intends distributing broadcast in the cause of temperance—or is it total abstinence? But a nod's as good as a wink to a blind horse!

I am, Sirs, yours faithfully,

Sept. 24th, 1900. J. W. C.

*To the Editors of* THE LANCET.

SIRS,—Your remarks in regard to the prescribing of sal volatile and chloric ether mixtures for dipsomaniacs are perfectly just. I recollect dispensing the following prescription for a lady: Compound tincture of cardamoms, three ounces; compound spirit of ammonia, three ounces; and spirit of chloroform, two ounces; a small spoonful in water every three hours. The lady consumed three or four bottles of this per day when the dyspeptic flatulence (!) was particularly bad. This was done while the medical attendant was in charge of the case. It was really an instance of substituting one tipple for another. Two other instances in my own experience of the abuse of hysteria and flatulence mixtures might also be mentioned, but the cause and effect were the same—addiction to the brandy bottle. In all cases the original intention of the prescriber was at first adhered to, but the alcohol in the physic soon made its presence felt.

I am, Sirs, yours faithfully,

Sept. 24th, 1900. PHAR. CHEM.

## A SINGULAR STORY OF HYPNOTISM.

MEDICAL subjects are, with few exceptions, unsuitable for discussion in the columns of ordinary newspapers, and nothing but harm is likely to result from this kind of publicity being given to clinical reports of hospital cases. Journalistic enterprise, which has on many occasions carried its votaries too far, concerns itself but little with questions of medical etiquette. This may, perhaps, be the reason why the *Daily Mail* of Sept. 24th devotes rather more than a column to the description of a visit to the British Hospital for Mental Disorders and Brain Diseases ("Forbes Winslow Memorial"), 208, Euston-road, N.W. The article has no signature of any kind nor anything to indicate the writer's position; his condemnation of what he professes to have seen is very emphatic, so it will be better to quote his own words rather than to attempt a summary of them.

"..... I had been invited to witness a night or two ago the hypnotic transferences which take place regularly at this institution, and been assured that the physician who attends 'adopts the same experiments as followed out by the late Professor Charcot at the Salpêtrière School, Paris, with equal success.' ..... It was the night of the week upon which Dr. Forbes Winslow himself attends to see the patients. ..... The doctor sat ..... in a ..... room on the first-floor front; and waiting in readiness behind him was a clean-shaven youth, thick-set, with his hair plastered over his forehead and the general cut of the valet. This turned out to be a 'professional medium' and the doctor called him 'May.' The first patient shown in was a melancholy looking, feeble, vacant man, who was under treatment for depression. ..... May, the medium, was seated opposite to the patient and was, the doctor asserted, hypnotised. The pair joined hands, and May pulled and contorted and grimaced until the good doctor cried 'Wake!' when the medium instantly ..... emerged from the hypnosis in which he purported to have been. 'Now you are better,' said the doctor to the patient. 'Look at the change,' he cried to me; and truly a weary smile was for the time evicting the gloom from the sufferer's face. ..... Then came ..... a woman of 30 whose mind was obsessed with what is known as an 'imperative idea.' ..... The ..... physician ..... did not hypnotise this patient at all, any more than he had hypnotised any other patient. He did not even profess to do so. What he did profess to do was to hypnotise May and to assure that unfortunate medium that he, the medium, had the woman's confused feelings now. ..... There were other patients, but here the doctor switched off to hypnotise May for my special benefit and to explain that while he was in a state of hypnosis he could feel the various symptoms which had been transferred from patients. ....."

The following letter appeared in the *Daily Mail* of Sept. 26th:—

"*To the Editor of the 'Daily Mail.'*

"It is the duty of the physician to endeavour to relieve suffering in the way which appears to him to be the most advisable.

"In the remarks referring to this subject which appeared in your issue of yesterday you apparently regard this treatment of nervous diseases by transference as novel and 'strange.' The first physicians who brought this to my personal knowledge were Prof. Lombroso of Turin and Dr. Gorodichze of Paris. It was the opinion of these gentlemen that some cases of nervous disease, which in the old days would become chronic in their nature, were now amenable to the methods I am adopting at my hospital.

"Transference was largely used by Dr. Luys at La Charité Hospital, Paris, and an article which appears in the *Fortnightly Review* for August of 1890 shows that even 10 years ago this treatment was recognised in France. In cases where an indirect 'suggestion' is required it can only be obtained by transference.

"33, Devonshire-street, W., Sept. 25th." "FORBES WINSLOW.

## TO MEDICAL FREEMASONS.

*To the Editors of* THE LANCET.

SIRS,—Will you allow me to point out to those who are brother Masons as well as brothers in the medical profession that at the elections to be held at the Royal Masonic Institution for Girls and the Royal Masonic Institution for Boys on Oct. 11th and Oct. 12th respectively there are two "medical" girl candidates (No. 17 and No. 24 on the list) and one "medical" boy candidate (No. 13). I have reason to think that previous appeals such as this in your columns have done much good and trust you will find room for these few lines.

I am, Sirs, yours faithfully,

Sept. 24th, 1900. P. Z.

## CHRONIC URETHRITIS.

*To the Editors of* THE LANCET.

SIRS,—A B contracted urethritis 18 months ago. After using all the remedies—protargol, largine, &c.—without any avail everything was stopped. Microscopic examination showed only streptococci and pus. At present with the slight running drop of pus, and that only occasionally, he suffers from intense painless chordee every morning with headache. I shall feel grateful if any of my *confrères* will give me the benefit of their advice. The patient is 40 years of age, grand physique, and most abstemious, and he has means.

I am, Sirs, yours faithfully,

Sept. 6th, 1900. SOUTH AFRICAN.

---

*Bowers.*—The gentleman mentioned by our correspondent had better apply to one of the usual agents. We should not advise anyone to go to South Africa at present on the chance of picking up work, but if he went out to fill some definite post matters would be different. We presume the qualification was obtained prior to 1886.

*A. F.*—Our correspondent will find our opinion of the preparations in THE LANCET of June 16th (p. 1750) and August 11th, 1900 (pp. 406 and 454). Some correspondence on this subject will also be found in THE LANCET of June 30th (p. 1908) and July 7th, 1900 (p. 52).

*B. B. G.*—The address of the Society for the Relief of Widows and Orphans of Medical Men is 11, Chandos-street, Cavendish-square, W.

*Sixty.*—Our correspondent must consult his usual medical attendant. We never give medical advice.

ERRATUM.—We regret that in our report of the meeting of the Section of Physiology at the meeting of the British Medical Association published in THE LANCET of August 18th, p. 505, the name of Dr. L. J. J. Muskins was erroneously printed as Maskens.

## METEOROLOGICAL READINGS.

# Medical Diary for the ensuing Week.

## OPERATIONS.

### METROPOLITAN HOSPITALS.

**MONDAY (1st).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.).

**TUESDAY (2nd).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

**WEDNESDAY (3rd).**—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.)

**THURSDAY (4th).**—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.) University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

**FRIDAY (5th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

**SATURDAY (6th).**—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

## SOCIETIES.

**WEDNESDAY (3rd).**—OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Dr. Roberts and others. Paper:—Dr. Herman: On Subcutaneous Symphysectomy.

**FRIDAY (5th).**—WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith, W.).—8.30 P.M. The President (Dr. F. F. Schacht): A Few Observations on the Early Treatment of Abdominal Symptoms. (Inaugural Address.)

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich-road, S.E.).—8.45 P.M. Election of Officers and Members. Exhibition of Clinical Cases and Specimens by Dr. Scholefield, Dr. Toogood, and Mr. G. C. Williams.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**MONDAY (1st).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. T. Colcott Fox: Consultation. (Skin.)

**TUESDAY (2nd).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. J. E. Squire: Consultation. (Medical.)

**WEDNESDAY (3rd).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. A. Hillier: Consultation. Medical. 5-7 P.M. Dr. W. J. Horne: Class. Practical Rhinology and Laryngology. Demonstration II.

**THURSDAY (4th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. Hutchinson: Consultation. (Surgical.)

**FRIDAY (5th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. R. Lake: Consultation. (Ear.)

# EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Lectures, original articles, and reports should be written on one side of the paper only,* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

# MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1900, which was completed with the issue of June 30th, and the Title-page to the Volume, were given in THE LANCET of July 7th.

### VOLUMES AND CASES.

VOLUMES for the first half of the year 1900 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

| FOR THE UNITED KINGDOM. | | TO THE COLONIES AND ABROAD. | |
|---|---|---|---|
| One Year ... ... ... | £1 12 6 | One Year ... ... ... | £1 14 8 |
| Six Months ... ... ... | 0 16 3 | Six Months ... ... ... | 0 17 4 |
| Three Months ... ... | 0 8 2 | Three Months ... ... | 0 8 2 |

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

**During the week marked copies of the following newspapers have been received:** *Health, Cork Herald, Sussex Daily News, Perthshire Courier, Literary Digest, Bristol Times, Times of India, Pioneer Mail, Citizen, Architect, Builder, Scotsman, Liverpool Daily Post, Leeds Mercury, Nottingham Guardian, Bristol Mercury, Yorkshire Post, Essex Herald, Manchester Guardian, Birmingham Daily Post, Sheffield Independent, East Dorset Herald, Norfolk Standard, Hertfordshire Mercury, Daily Gleaner (Kingston, Jamaica), Mining Journal, City Press, Staffordshire Sentinel, Essex County Chronicle, Inquirer, Warwick Times, North Middlesex Chronicle, Country Sport, Local Government Chronicle, Local Government Journal, Surrey Advertiser, Midland Weekly News, Australasian Medical Gazette, Cambridge Times, Sanitary Record, Springburn Express, Retford Times, Hereford Times, Folkestone Express, Oxford Chronicle, Scarborough Post, Herne Bay Press, Leicester Post, &c.*

## Communications, Letters, &c., have been received from—

A.—Mr. G. M. Asher, Lond.; Dr. J. F. Armstrong, South Shields; Dr. S. M. Alcántara, La Guaira, South America; M. Pierre Apéry, Constantinople; Messrs. Armour and Co., Lond.; Messrs. Allen and Hanburys, Lond.; A. W. S.

B.—Dr. J. Barr, Liverpool; Mr. R. R. Bugtani, Karachi, India; T. B. Browne, Ltd., Lond.; Bexhill Publishing Co.; Mrs. Blackmore, Lond.; Birkbeck Institute, Lond.; Bowers, Bedford; Dr. J. C. Buckley, Nottingham; Mr. L. E Brancher, Leamington; *British Food Journal*, Editor of; Messrs. Burroughs Wellcome and Co., Lond.

Quarter Page, £1 10s. Half a Page, £2 15s. An Entire Page, £5 5s.

Terms for Position Pages and Serial Insertions on application.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France,—J. ASTIER, 8, Rue Traversière, Asnières, Paris.
